angr.calling_conventions.**register_syscall_cc**(*arch*, *os*, *cc*)

angr.calling_conventions.**cls_**

alias of *SimCCUsercall*

angr.calling_conventions.**is_stack_probe**(*func*)

Return True if `func` is a Windows stack-probe / alloca-probe helper (`__chkstk` / `__alloca_probe`).

**Return type**
bool

**Parameters**
**func** (Function)

angr.calling_conventions.**call_clobbered_regs**(*cc*, *target*, *arch*)

Return the caller-saved (clobbered) register names for a call to `target` under calling convention `cc`.

This function is aware of special behaviors of functions, such as stack-probe callees (`__chkstk` / `__alloca_probe`). Future logic for other special functions may be added to this function as needed.

**Return type**
list[str]

**Parameters**

- **cc** (SimCC)
- **target** (Function | *None*)
- **arch** (*archinfo.Arch*)

## 10.10 angr.code_location

**class** angr.code_location.**CodeLocation**

Bases: Generic[BlockAddr, StmtIdx, Context]

Stands for a specific program point by specifying basic block address and statement ID (for IRSBs), or SimProcedure name (for SimProcedures).

**__init__**(*block_addr*, *stmt_idx*, *sim_procedure=None*, *ins_addr=None*, *context=None*, *block_idx=None*, ***kwargs*)

Constructor.

**Parameters**

- **block_addr** (BlockAddr) – Address of the block
- **stmt_idx** (StmtIdx) – Statement ID. None for SimProcedures or if the code location is meant to refer to the entire block.
- **sim_procedure** (*class*) – The corresponding SimProcedure class.
- **ins_addr** (int | None) – The instruction address.
- **context** (Context) – A tuple that represents the context of this CodeLocation in contextual mode, or None in contextless mode.
- **kwargs** – Optional arguments, will be stored, but not used in __eq__ or __hash__.
- **block_idx** (*int | None*)

**block_addr**

**stmt_idx**

**sim_procedure**

**ins_addr**

**context**

**block_idx**

**info: dict[str, Any] | None**

**property short_repr**

**class** angr.code_location.**ExternalCodeLocation**

Bases: *CodeLocation*

Stands for a program point that originates from outside an analysis' scope. i.e. a value loaded from rdi in a callee where the caller has not been analyzed.

**call_string**

**class** angr.code_location.**AILCodeLocation**

Bases: object

A code location that refers precisely to a statement of an AIL block, with an optional instruction address.

**addr: int**

**block_idx: int**

**stmt_idx:** *int*

**insn_addr:** *int | None = None*

**static make_extern**(*idx*)

**Parameters**
**idx** (*int*)

**property insn_addr_unwrap:** *int*

**property is_extern:** *bool*

**property extern_idx_unwrap:** *int*

**property extern_idx:** *int | None*

**static from_codeloc**(*codeloc*)

**Return type**
*AILCodeLocation*

**Parameters**
**codeloc** (CodeLocation)

**property bbl_addr**

**property block_addr**

**property ins_addr**

**__init__**(*addr*, *block_idx*, *stmt_idx*, *insn_addr=None*)

**Parameters**

- **addr** (*int*)
- **block_idx** (*int*)
- **stmt_idx** (*int*)
- **insn_addr** (*int | None*)

**Return type**
None

## 10.11 angr.codenode

angr.codenode.**repr_addr**[*K: (int, SootMethodDescriptor)*](*addr*)

**Return type**
str

**Parameters**
**addr** (*K*)

**class** angr.codenode.**CodeNode**

Bases: Generic[K]

The base class of nodes in a function graph.

__init__(*addr*, *size*, *thumb=False*)

**Parameters**

- **addr** (*K*)
- **size** (*int*)

addr

size: int

thumb

set_owner(*func*)

**Return type**
None

property owner: *Function* | None

The Function this node belongs to, or None if it was never registered with one or that Function is gone.

successors()

**Return type**
list[*CodeNode*]

predecessors()

**Return type**
list[*CodeNode*]

is_hook = None

class angr.codenode.**BlockNode**

Bases: *CodeNode*[K], Generic[K]

Represents a block of code in a function graph.

is_hook = False

__init__(*addr*, *size*, *bytestr=None*, *thumb=False*, *delta=None*)

**Parameters**

- **bytestr** (bytes | None) – The bytes of the block, given only when the bytes are from user-specified binary code.
- **delta** (int | None) – The block's bytes are at addr + delta. Defaults to -1 for ARM Thumb nodes. Note that delta is not part of the identity of a BlockNode.
- **addr** (*K*)
- **size** (*int*)
- **thumb** (*bool*)

delta

property manual_bytes: bool

True if the node has user-supplied bytes rather than reading bytes from the loader.

**property raw_bytestr: bytes | None**

The bytes of the block if they were supplied by the user. None otherwise.

**bytestr**(*project*, *original=True*)

Get the bytes of the block.

**Parameters**

- **project** (*Project*) – The angr Project to use to read the bytes if they are not user-supplied.
- **original** (bool) – Whether to read the original bytes from the loader (True) or the potentially patched bytes (False).

**Return type**
bytes | None

**class** angr.codenode.**SootBlockNode**

Bases: *BlockNode*[SootMethodDescriptor]

Represents a Soot block of code in a function graph.

**stmts**

**class** angr.codenode.**FuncNode**

Bases: *CodeNode*[K], Generic[K]

Represents a function callee in a function graph.

**__init__**(*addr*, *func_name=None*, ***kwargs*)

**Parameters**

- **addr** (*K*)
- **func_name** (*str | None*)

**func_name**

**property is_addr_known: bool**

**class** angr.codenode.**HookNode**

Bases: *CodeNode*[K], Generic[K]

Represents a hook in a function graph.

**is_hook = True**

**__init__**(*addr*, *size*, *sim_procedure*, ***kwargs*)

**Parameters**
**sim_procedure** (*SimProcedure* | None) – the the sim_procedure class

**sim_procedure**

**class** angr.codenode.**SyscallNode**

Bases: *HookNode*[K], Generic[K]

Represents a syscall in a function graph.

**is_hook = False**

**sim_procedure**

## 10.12 angr.concretization_strategies

**class** angr.concretization_strategies.**SimConcretizationStrategy**

Bases: object

Concretization strategies control the resolution of symbolic memory indices in SimuVEX. By subclassing this class and setting it as a concretization strategy (on state.memory.read_strategies and state.memory.write_strategies), SimuVEX's memory index concretization behavior can be modified.

**__init__**(*filter=None*, *exact=True*)

Initializes the base SimConcretizationStrategy.

**Parameters**

- **filter** – A function, taking arguments of (SimMemory, claripy.AST) that determines if this strategy can handle resolving the provided AST.
- **exact** – A flag (default: True) that determines if the convenience resolution functions provided by this class use exact or approximate resolution.

**concretize**(*memory*, *addr*, ***kwargs*)

Concretizes the address into a list of values. If this strategy cannot handle this address, returns None.

**copy**()

Returns a copy of the strategy, if there is data that should be kept separate between states. If not, returns self.

**merge**(*others*)

Merges this strategy with others (if there is data that should be kept separate between states. If not, is a no-op.

**class** angr.concretization_strategies.**SimConcretizationStrategyAny**

Bases: *SimConcretizationStrategy*

Concretization strategy that returns any single solution.

**class** angr.concretization_strategies.**SimConcretizationStrategyControlledData**

Bases: *SimConcretizationStrategy*

Concretization strategy that constraints the address to controlled data. Controlled data consists of symbolic data and the addresses given as arguments. memory.

**class** angr.concretization_strategies.**SimConcretizationStrategyEval**

Bases: *SimConcretizationStrategy*

Concretization strategy that resolves an address into some limited number of solutions. Always handles the concretization, but only returns a maximum of limit number of solutions. Therefore, should only be used as the fallback strategy.

**class** angr.concretization_strategies.**SimConcretizationStrategyMax**

Bases: *SimConcretizationStrategy*

Concretization strategy that returns the maximum address.

**class** angr.concretization_strategies.**SimConcretizationStrategyNonzero**

Bases: *SimConcretizationStrategy*

Concretization strategy that returns any non-zero solution.

**class** angr.concretization_strategies.**SimConcretizationStrategyNonzeroRange**

Bases: *SimConcretizationStrategy*

Concretization strategy that resolves a range in a non-zero location.

**class** angr.concretization_strategies.**SimConcretizationStrategyNorepeats**

Bases: *SimConcretizationStrategy*

Concretization strategy that resolves addresses, without repeating.

**class** angr.concretization_strategies.**SimConcretizationStrategyNorepeatsRange**

Bases: *SimConcretizationStrategy*

Concretization strategy that resolves a range, with no repeats.

**class** angr.concretization_strategies.**SimConcretizationStrategyRange**

Bases: *SimConcretizationStrategy*

Concretization strategy that resolves addresses to a range.

**class** angr.concretization_strategies.**SimConcretizationStrategySingle**

Bases: *SimConcretizationStrategy*

Concretization strategy that ensures a single solution for an address.

**class** angr.concretization_strategies.**SimConcretizationStrategySolutions**

Bases: *SimConcretizationStrategy*

Concretization strategy that resolves an address into some limited number of solutions.

**class** angr.concretization_strategies.**SimConcretizationStrategyUnlimitedRange**

Bases: *SimConcretizationStrategy*

Concretization strategy that resolves addresses to a range without checking if the number of possible addresses is within the limit.

### 10.12.1 angr.concretization_strategies.any

**class** angr.concretization_strategies.any.**SimConcretizationStrategyAny**

Bases: *SimConcretizationStrategy*

Concretization strategy that returns any single solution.

### 10.12.2 angr.concretization_strategies.any_named

**class** angr.concretization_strategies.any_named.**SimConcretizationStrategyAnyNamed**

Bases: *SimConcretizationStrategy*

Concretization strategy that returns any single solution and creates a BVS at the resulting address.

### 10.12.3 angr.concretization_strategies.base

**class** angr.concretization_strategies.base.**SimConcretizationStrategy**

Bases: object

Concretization strategies control the resolution of symbolic memory indices in SimuVEX. By subclassing this class and setting it as a concretization strategy (on state.memory.read_strategies and state.memory.write_strategies), SimuVEX's memory index concretization behavior can be modified.

**__init__**(*filter=None*, *exact=True*)

Initializes the base SimConcretizationStrategy.

**Parameters**

- **filter** – A function, taking arguments of (SimMemory, claripy.AST) that determines if this strategy can handle resolving the provided AST.
- **exact** – A flag (default: True) that determines if the convenience resolution functions provided by this class use exact or approximate resolution.

**concretize**(*memory*, *addr*, ***kwargs*)

Concretizes the address into a list of values. If this strategy cannot handle this address, returns None.

**copy**()

Returns a copy of the strategy, if there is data that should be kept separate between states. If not, returns self.

**merge**(*others*)

Merges this strategy with others (if there is data that should be kept separate between states. If not, is a no-op.

### 10.12.4 angr.concretization_strategies.controlled_data

**class** angr.concretization_strategies.controlled_data.**SimConcretizationStrategyControlledData**

Bases: *SimConcretizationStrategy*

Concretization strategy that constraints the address to controlled data. Controlled data consists of symbolic data and the addresses given as arguments. memory.

### 10.12.5 angr.concretization_strategies.eval

**class** angr.concretization_strategies.eval.**SimConcretizationStrategyEval**

Bases: *SimConcretizationStrategy*

Concretization strategy that resolves an address into some limited number of solutions. Always handles the concretization, but only returns a maximum of limit number of solutions. Therefore, should only be used as the fallback strategy.

### 10.12.6 angr.concretization_strategies.logging

**class** angr.concretization_strategies.logging.**SimConcretizationStrategyLogging**

Bases: *SimConcretizationStrategy*

Concretization strategy that logs concretization results from another strategy.

### 10.12.7 angr.concretization_strategies.max

**class** angr.concretization_strategies.max.**SimConcretizationStrategyMax**

Bases: *SimConcretizationStrategy*

Concretization strategy that returns the maximum address.

### 10.12.8 angr.concretization_strategies.nonzero

**class** angr.concretization_strategies.nonzero.**SimConcretizationStrategyNonzero**

Bases: *SimConcretizationStrategy*

Concretization strategy that returns any non-zero solution.

### 10.12.9 angr.concretization_strategies.nonzero_range

**class** angr.concretization_strategies.nonzero_range.**SimConcretizationStrategyNonzeroRange**

Bases: *SimConcretizationStrategy*

Concretization strategy that resolves a range in a non-zero location.

### 10.12.10 angr.concretization_strategies.norepeats

**class** angr.concretization_strategies.norepeats.**SimConcretizationStrategyNorepeats**

Bases: *SimConcretizationStrategy*

Concretization strategy that resolves addresses, without repeating.

### 10.12.11 angr.concretization_strategies.norepeats_range

**class**
angr.concretization_strategies.norepeats_range.**SimConcretizationStrategyNorepeatsRange**

Bases: *SimConcretizationStrategy*

Concretization strategy that resolves a range, with no repeats.

### 10.12.12 angr.concretization_strategies.range

**class** angr.concretization_strategies.range.**SimConcretizationStrategyRange**

Bases: *SimConcretizationStrategy*

Concretization strategy that resolves addresses to a range.

### 10.12.13 angr.concretization_strategies.signed_add

**class** angr.concretization_strategies.signed_add.**SimConcretizationStrategySignedAdd**

Bases: *SimConcretizationStrategy*

Concretization strategy that changes additions of big offsets to subtractions of small offsets.

### 10.12.14 angr.concretization_strategies.single

**class** angr.concretization_strategies.single.**SimConcretizationStrategySingle**

Bases: *SimConcretizationStrategy*

Concretization strategy that ensures a single solution for an address.

### 10.12.15 angr.concretization_strategies.solutions

**class** angr.concretization_strategies.solutions.**SimConcretizationStrategySolutions**

Bases: *SimConcretizationStrategy*

Concretization strategy that resolves an address into some limited number of solutions.

### 10.12.16 angr.concretization_strategies.unlimited_range

**class** angr.concretization_strategies.unlimited_range.**SimConcretizationStrategyUnlimitedRange**

Bases: *SimConcretizationStrategy*

Concretization strategy that resolves addresses to a range without checking if the number of possible addresses is within the limit.

## 10.13 angr.distributed

angr.distributed provides a simple implementation for conducting long-running symbolic-execution-based tasks.

**class** angr.distributed.**Server**

Bases: object

Server implements the analysis server with a series of control interfaces exposed.

**Variables**

- **project** – An instance of angr.Project.
- **spill_yard** (*str*) – A directory to store spilled states.
- **db** (*str*) – Path of the database that stores information about spilled states.
- **max_workers** (*int*) – Maximum number of workers. Each worker starts a new process.
- **max_states** (*int*) – Maximum number of active states for each worker.

- **staging_max** (*int*) – Maximum number of inactive states that are kept into memory before spilled onto the disk and potentially be picked up by another worker.
- **bucketizer** (*bool*) – Use the Bucketizer exploration strategy.
- **_worker_exit_callback** – A method that will be called upon the exit of each worker.

**__init__**(*project*, *spill_yard=None*, *db=None*, *max_workers=None*, *max_states=10*, *staging_max=10*, *bucketizer=True*, *recursion_limit=1000*, *worker_exit_callback=None*, *techniques=None*, *add_options=None*, *remove_options=None*)

**inc_active_workers**()

**dec_active_workers**()

**stop**()

**property active_workers**

**property stopped**

**on_worker_exit**(*worker_id*, *stashes*)

**run**()

### Submodules

*server*
*worker*

## 10.13.1 angr.distributed.server

**class** angr.distributed.server.**Server**

Bases: object

Server implements the analysis server with a series of control interfaces exposed.

**Variables**

- **project** – An instance of angr.Project.
- **spill_yard** (*str*) – A directory to store spilled states.
- **db** (*str*) – Path of the database that stores information about spilled states.
- **max_workers** (*int*) – Maximum number of workers. Each worker starts a new process.
- **max_states** (*int*) – Maximum number of active states for each worker.
- **staging_max** (*int*) – Maximum number of inactive states that are kept into memory before spilled onto the disk and potentially be picked up by another worker.
- **bucketizer** (*bool*) – Use the Bucketizer exploration strategy.
- **_worker_exit_callback** – A method that will be called upon the exit of each worker.

**__init__**(*project*, *spill_yard=None*, *db=None*, *max_workers=None*, *max_states=10*, *staging_max=10*, *bucketizer=True*, *recursion_limit=1000*, *worker_exit_callback=None*, *techniques=None*, *add_options=None*, *remove_options=None*)

**inc_active_workers**()

**dec_active_workers**()

**stop**()

**property active_workers**

**property stopped**

**on_worker_exit**(*worker_id*, *stashes*)

**run**()

### 10.13.2 angr.distributed.worker

**class** angr.distributed.worker.**BadStatesDropper**

Bases: *ExplorationTechnique*

Dumps and drops states that are not "active".

**__init__**(*vault*, *db*)

**class** angr.distributed.worker.**ExplorationStatusNotifier**

Bases: *ExplorationTechnique*

Force the exploration to stop if the server.stop is True.

**__init__**(*server_state*)

**Parameters**
**server_state** (*dict*)

**class** angr.distributed.worker.**Worker**

Bases: object

Worker implements a worker thread/process for conducting a task.

**__init__**(*worker_id*, *server*, *server_state*, *recursion_limit=None*, *techniques=None*, *add_options=None*, *remove_options=None*)

**start**()

**run**(*initializer*)

**Parameters**
**initializer** (Initializer)

## 10.14 angr.emulator

**class** angr.emulator.**Emulator**

Bases: object

Emulator is a utility that adapts an angr *SuccessorsEngine* to a more user-friendly interface for concrete execution. It only supports concrete execution.

Saftey: This class is not thread-safe. It should only be used in a single-threaded context. It can be safely shared between multiple threads, provided that only one thread is using it at a time.

**__init__**(*engine*, *init_state*)

**Parameters**

- **engine** (*SuccessorsEngine*) – The *SuccessorsEngine* to use for emulation.
- **init_state** (*SimState*) – The initial state to use for emulation.

**property state: *SimState***

The current state of the emulator.

**property breakpoints: set[int]**

The set of currently set breakpoints.

**add_breakpoint**(*addr*)

Add a breakpoint at the given address.

**Parameters**
**addr** (int) – The address to set the breakpoint at.

**Return type**
None

**remove_breakpoint**(*addr*)

Remove a breakpoint at the given address, if present.

**Parameters**
**addr** (int) – The address to remove the breakpoint from.

**Return type**
None

**run**(*num_inst=None*)

Execute the emulator.

**Return type**
*EmulatorStopReason*

**Parameters**
**num_inst** (*int | None*)

**exception** angr.emulator.**EmulatorException**

Bases: *AngrError*

Base class for exceptions raised by the Emulator.

**class** angr.emulator.**EmulatorStopReason**

Bases: Enum

Enum representing the reason for stopping the emulator.

**INSTRUCTION_LIMIT = 'instruction_limit'**

**BREAKPOINT = 'breakpoint'**

**NO_SUCCESSORS = 'no_successors'**

**MEMORY_ERROR = 'memory_error'**

**FAILURE = 'failure'**

**EXIT = 'exit'**

**exception** angr.emulator.**EngineException**

Bases: *EmulatorException*

Exception raised when the emulator encounters an unhandlable error in the engine.

**exception** angr.emulator.**StateDivergedException**

Bases: *EmulatorException*

Exception raised when an engine returns multiple successors.

## 10.15 angr.engines

**class** angr.engines.**HeavyResilienceMixin**

Bases: *VEXResilienceMixin*, *ClaripyDataMixin*

**class** angr.engines.**HeavyVEXMixin**

Bases: *SuccessorsEngine*, *ClaripyDataMixin*, *SimStateStorageMixin*, *VEXMixin*, *VEXLifter*

Execution engine based on VEX, Valgrind's IR.

Responds to the following parameters to the step stack:

- irsb: The PyVEX IRSB object to use for execution. If not provided one will be lifted.
- skip_stmts: The number of statements to skip in processing
- last_stmt: Do not execute any statements after this statement
- whitelist: Only execute statements in this set
- thumb: Whether the block should be force to be lifted in ARM's THUMB mode.
- **extra_stop_points:**
  An extra set of points at which to break basic blocks
- opt_level: The VEX optimization level to use.
- insn_bytes: A string of bytes to use for the block instead of the project.
- size: The maximum size of the block, in bytes.
- num_inst: The maximum number of instructions.
- traceflags: traceflags to be passed to VEX. (default: 0)

**class** angr.engines.**HooksMixin**

Bases: *SuccessorsEngine*, *ProcedureMixin*

A SimEngine mixin which adds a SimSuccessors handler which will look into the project's hooks and run the hook at the current address.

Will respond to the following parameters provided to the step stack:

- procedure: A SimProcedure instance to force-run instead of consulting the current hooks
- ret_to: An address to force-return-to at the end of the procedure

**class** angr.engines.**ProcedureEngine**

Bases: *ProcedureMixin*, *SuccessorsEngine*

A SimEngine that you may use if you only care about processing SimProcedures. *Requires* the procedure kwarg to be passed to process.

**class** angr.engines.**ProcedureMixin**

Bases: object

A mixin for SimEngine which adds the `process_procedure` method for calling a SimProcedure and adding its results to a SimSuccessors.

**process_procedure**(*state*, *successors*, *procedure*, *ret_to=None*, *arguments=None*, ***kwargs*)

**class** angr.engines.**SimEngine**

Bases: Generic[StateType, ResultType]

A SimEngine is a type which understands how to perform execution on a state.

**state: StateType**

**__init__**(*project*)

**Parameters**
**project** (Project)

**class** angr.engines.**SimEngineFailure**

Bases: *SuccessorsEngine*, *ProcedureMixin*

**class** angr.engines.**SimEngineSyscall**

Bases: *SuccessorsEngine*, *ProcedureMixin*

A SimEngine mixin which adds a successors handling step that checks if a syscall was just requested and if so handles it as a step.

**class** angr.engines.**SimEngineUnicorn**

Bases: *SuccessorsEngine*

Concrete execution in the Unicorn Engine, a fork of qemu.

Responds to the following parameters in the step stack:

- step: How many basic blocks we want to execute
- extra_stop_points: A collection of addresses at which execution should halt

**__init__**(*project*)

**Parameters**
**project** (Project)

**class** angr.engines.**SimInspectMixin**

Bases: *VEXMixin*

**handle_vex_block**(*irsb*)

**class** angr.engines.**SimSuccessors**

Bases: object

This class serves as a categorization of all the kinds of result states that can come from a SimEngine run.

**Variables**

- **addr** (*int*) – The address at which execution is taking place, as a python int
- **initial_state** – The initial state for which execution produced these successors
- **engine** – The engine that produced these successors
- **sort** (str | None) – A string identifying the type of engine that produced these successors

- **processed** (*bool*) – Whether or not the processing succeeded
- **description** (*str*) – A textual description of the execution step

The successor states produced by this run are categorized into several lists:

**Variables**

- **artifacts** (*dict*) – Any analysis byproducts (for example, an IRSB) that were produced during execution
- **successors** (list[]) – The "normal" successors. IP may be symbolic, but must have reasonable number of solutions
- **unsat_successors** (list[]) – Any successor which is unsatisfiable after its guard condition is added.
- **all_successors** (list[]) – successors + unsat_successors
- **flat_successors** (list[]) – The normal successors, but any symbolic IPs have been concretized. There is one state in this list for each possible value an IP may be concretized to for each successor state.
- **unconstrained_successors** (list[]) – Any state for which during the flattening process we find too many solutions.

A more detailed description of the successor lists may be found here: https://docs.angr.io/core-concepts/simulation#simsuccessors

**__init__**(*addr*, *initial_state*)

**Parameters**

- **addr** (*int* | *SootAddressDescriptor* | *None*)
- **initial_state** (HeavyState | *None*)

**property is_empty**

**add_successor**(*state*, *target*, *guard*, *jumpkind*, *add_guard=True*, *exit_stmt_idx=None*, *exit_ins_addr=None*, *source=None*)

Add a successor state of the SimRun. This procedure stores method parameters into state.scratch, does some housekeeping, and calls out to helper functions to prepare the state and categorize it into the appropriate successor lists.

**Parameters**

- **state** (SimState) – The successor state.
- **target** – The target (of the jump/call/ret).
- **guard** – The guard expression.
- **jumpkind** (*str*) – The jumpkind (call, ret, jump, or whatnot).
- **add_guard** (*bool*) – Whether to add the guard constraint (default: True).
- **exit_stmt_idx** (*int*) – The ID of the exit statement, an integer by default. 'default' stands for the default exit, and None means it's not from a statement (for example, from a SimProcedure).
- **exit_ins_addr** (*int*) – The instruction pointer of this exit, which is an integer by default.
- **source** (*int*) – The source of the jump (i.e., the address of the basic block).

class angr.engines.**SootMixin**

Bases: *SuccessorsEngine*, *ProcedureMixin*

Execution engine based on Soot.

**lift_soot**(*addr=None*, *the_binary=None*, ***kwargs*)

**get_unconstrained_simprocedure**()

**classmethod setup_callsite**(*state*, *args*, *ret_addr*, *ret_var=None*)

**static setup_arguments**(*state*, *args*)

**static prepare_return_state**(*state*, *ret_value=None*)

**static terminate_execution**(*statement*, *state*, *successors*)

**static prepare_native_return_state**(*native_state*)

Hook target for native function call returns.

Recovers and stores the return value from native memory and toggles the state, s.t. execution continues in the Soot engine.

class angr.engines.**SuccessorsEngine**

Bases: *SimEngine*[, *SimSuccessors*]

A mixin for SimEngine which implements `process` to perform common operations related to symbolic execution and dispatches to a `process_successors` method to fill a SimSuccessors object with the results.

**__init__**(*project*)

**Parameters**
**project** (*Project*)

**process**(*state*, ***kwargs*)

Perform execution with a state.

You should only override this method in a subclass in order to provide the correct method signature and docstring. You should override the `_process` method to do your actual execution.

**Parameters**

- **state** () – The state with which to execute. This state will be copied before modification.
- **inline** – This is an inline execution. Do not bother copying the state.
- **force_addr** – Force execution to pretend that we're working at this concrete address

**Return type**
*SimSuccessors*

**Returns**
A SimSuccessors object categorizing the execution's successor states

**process_successors**(*successors*, ***kwargs*)

Implement this function to fill out the SimSuccessors object with the results of stepping state.

In order to implement a model where multiple mixins can potentially handle a request, a mixin may implement this method and then perform a super() call if it wants to pass on handling to the next mixin.

Keep in mind python's method resolution order when composing multiple classes implementing this method. In short: left-to-right, depth-first, but deferring any base classes which are shared by multiple subclasses (the merge point of a diamond pattern in the inheritance graph) until the last point where they

would be encountered in this depth-first search. For example, if you have classes A, B(A), C(B), D(A), E(C, D), then the method resolution order will be E, C, B, D, A.

**Parameters**

- **state** – The state to manipulate
- **successors** (*SimSuccessors*) – The successors object to fill out
- **kwargs** – Any extra arguments. Do not fail if you are passed unexpected arguments.

**class** angr.engines.**SuperFastpathMixin**

Bases: *VEXSlicingMixin*

This mixin implements the superfastpath execution mode, which skips all but the last four instructions.

**handle_vex_block**(*irsb*)

**class** angr.engines.**TrackActionsMixin**

Bases: *HeavyVEXMixin*

**__init__**(**args*, ***kwargs*)

**handle_vex_block**(*irsb*)

**class** angr.engines.**UberEngine**

Bases: *SimEngineFailure*, *SimEngineSyscall*, *HooksMixin*, *SimEngineUnicorn*, *SuperFastpathMixin*, *TrackActionsMixin*, *SimInspectMixin*, *HeavyResilienceMixin*, *SootMixin*, *AILMixin*, *HeavyVEXMixin*

The default execution engine for angr. This engine includes mixins for most common functionality in angr, including VEX IR, unicorn, syscall handling, and simprocedure handling.

For some performance-sensitive applications, you may want to create a custom engine with only the necessary mixins.

**class** angr.engines.**UberEnginePcode**

Bases: *SimEngineFailure*, *SimEngineSyscall*, *HooksMixin*, *HeavyPcodeMixin*

### 10.15.1 angr.engines.ail

**class** angr.engines.ail.**AILCallStack**

Bases: *CallStack*

An implementation of state.callstack for AIL symbolic execution

Contains extra state for local vars and AIL calling conventions

**__init__**(**args*, ***kwargs*)

**copy_without_tail**(*memo*)

**class** angr.engines.ail.**AILMixin**

Bases: *SuccessorsEngine*

The SuccessorsEngine mixin for providing AIL symbolic execution support

**class** angr.engines.ail.**SimEngineAILSimState**

Bases: *SimEngineLightAIL*[, , bool, None]

A light engine for symbolically executing AIL

**__init__**(*project*, *successors*)

**Parameters**

- **project** (Project)
- **successors** (SimSuccessors)

**process**(*state*, ***, *block=None*, *whitelist=None*, ***kwargs*)

**Return type**
None

**Parameters**

- **state** (StateType)
- **block** (*Block | None*)
- **whitelist** (*set[int] | None*)

**property frame:** *AILCallStack*

**lift_addr**(*addr*)

**Return type**
*Clinic*

**Parameters**
**addr** (*int*)

**lift**(*state*)

**Return type**
Block

**Parameters**
**state** (*StateType | int | Address*)

angr.engines.ail.**ail_call_state**(*project*, *start_addr*, *args*, *lifter*, *mode='symbolic'*, *options=None*, *add_options=None*, *remove_options=None*, *plugin_preset='default'*, *memory_cls=None*, *callstack_cls=None*)

**Parameters**

- **project** (Project)
- **start_addr** (*int | Address | str*)
- **args** (*Iterable[claripy.ast.Bits]*)
- **lifter** (*Callable[[int], Clinic]*)
- **mode** (*str*)
- **options** (*set[str] | None*)
- **add_options** (*set[str] | None*)
- **remove_options** (*set[str] | None*)
- **plugin_preset** (*str*)
- **memory_cls** (*type[MemoryMixin] | None*)
- **callstack_cls** (*type[AILCallStack] | None*)

## Submodules

*callstack*
*engine_light*
*engine_successors*
*setup*

### angr.engines.ail.callstack

**class** angr.engines.ail.callstack.**AILCallStack**

Bases: *CallStack*

An implementation of state.callstack for AIL symbolic execution

Contains extra state for local vars and AIL calling conventions

**__init__**(**args*, ***kwargs*)

**copy_without_tail**(*memo*)

### angr.engines.ail.engine_light

**type** angr.engines.ail.engine_light.**StateType** = *SimState*[int, BV]

**type** angr.engines.ail.engine_light.**DataType** = Bits | Bool

**exception** angr.engines.ail.engine_light.**CallReached**

Bases: Exception

An exception to abort executing a block if we need to restart it with a call result

**class** angr.engines.ail.engine_light.**SimEngineAILSimState**

Bases: *SimEngineLightAIL*[, , bool, None]

A light engine for symbolically executing AIL

**__init__**(*project*, *successors*)

**Parameters**

- **project** (Project)
- **successors** (SimSuccessors)

**process**(*state*, *, *block=None*, *whitelist=None*, **kwargs*)

**Return type**
None

**Parameters**

- **state** (StateType)
- **block** (*Block | None*)
- **whitelist** (*set[int] | None*)

**property frame:** *AILCallStack*

**lift_addr**(*addr*)

**Return type**
*Clinic*

**Parameters**
**addr** (*int*)

**lift**(*state*)

**Return type**
Block

**Parameters**
**state** (StateType | *int* | *Address*)

### angr.engines.ail.engine_successors

**class** angr.engines.ail.engine_successors.**AILMixin**

Bases: *SuccessorsEngine*

The SuccessorsEngine mixin for providing AIL symbolic execution support

### angr.engines.ail.setup

angr.engines.ail.setup.**ail_call_state**(*project*, *start_addr*, *args*, *lifter*, *mode='symbolic'*, *options=None*, *add_options=None*, *remove_options=None*, *plugin_preset='default'*, *memory_cls=None*, *callstack_cls=None*)

**Parameters**

- **project** (Project)
- **start_addr** (*int | Address | str*)
- **args** (*Iterable[claripy.ast.Bits]*)
- **lifter** (*Callable[[int], Clinic]*)
- **mode** (*str*)

- **options** (*set[str] | None*)
- **add_options** (*set[str] | None*)
- **remove_options** (*set[str] | None*)
- **plugin_preset** (*str*)
- **memory_cls** (*type[MemoryMixin] | None*)
- **callstack_cls** (*type[AILCallStack] | None*)

### 10.15.2 angr.engines.engine

**class** angr.engines.engine.**SimEngine**

Bases: Generic[StateType, ResultType]

A SimEngine is a type which understands how to perform execution on a state.

**state: StateType**

**__init__**(*project*)

**Parameters**
**project** (*Project*)

### 10.15.3 angr.engines.failure

**class** angr.engines.failure.**SimEngineFailure**

Bases: *SuccessorsEngine*, *ProcedureMixin*

### 10.15.4 angr.engines.hook

**class** angr.engines.hook.**HooksMixin**

Bases: *SuccessorsEngine*, *ProcedureMixin*

A SimEngine mixin which adds a SimSuccessors handler which will look into the project's hooks and run the hook at the current address.

Will respond to the following parameters provided to the step stack:

- procedure: A SimProcedure instance to force-run instead of consulting the current hooks
- ret_to: An address to force-return-to at the end of the procedure

### 10.15.5 angr.engines.icicle

icicle.py: An angr engine that uses Icicle to execute code.

**class** angr.engines.icicle.**IcicleEngine**

Bases: *SuccessorsEngine*

An angr engine that uses Icicle to execute concrete states. The purpose of this implementation is to provide a high-performance concrete execution engine in angr. While historically, angr has focused on symbolic execution, better support for concrete execution enables new use cases such as fuzzing in angr. This is ideal for testing bespoke binary targets, such as microcontroller firmware, which may be difficult to correctly harness for use with traditional fuzzing engines.

This class is the base class for the Icicle engine. It implements execution by creating an Icicle instance, copying the state from angr to Icicle, and then running the Icicle instance. The results are then copied back to the angr state. The Icicle instance is cached on the engine and reused across runs: the first call takes a snapshot of the fresh

VM, and subsequent calls either continue with the cached emu (same-run successors) or restore the snapshot and delta-sync the input state (branches).

For a more complete implementation, use the UberIcicleEngine class, which intends to provide a more complete set of features, such as hooks and syscalls.

**class** angr.engines.icicle.**UberIcicleEngine**

Bases: *SimEngineFailure*, *SimEngineSyscall*, *HooksMixin*, *IcicleEngine*

An extension of the IcicleEngine that uses mixins to add support for syscalls and hooks. Most users will prefer to use this engine instead of the IcicleEngine directly.

### 10.15.6 angr.engines.light

**class** angr.engines.light.**ArithmeticExpression**

Bases: object

**Add = 0**

**Sub = 1**

**Or = 2**

**And = 4**

**RShift = 8**

**LShift = 16**

**Mul = 32**

**Xor = 64**

**CONST_TYPES = (<class 'int'>, <class 'angr.ailment.expression.Const'>)**

**__init__**(*op*, *operands*)

**op**

**operands**

**static try_unpack_const**(*expr*)

**class** angr.engines.light.**RegisterOffset**

Bases: object

**__init__**(*bits*, *reg*, *offset*)

**reg**

**offset**

**property bits**

**property symbolic**

**class** angr.engines.light.**SimEngineLight**

Bases: *SimEngine*[StateType, ResultType], Generic[StateType, DataType_co, BlockType, ResultType]

A full-featured engine base class, suitable for static analysis

**block:** BlockType

**state:** StateType

**stmt_idx:** int

**ins_addr:** int

**tmps:** dict[int, DataType_co]

**__init__**(*project*, *logger=None*)

**Parameters**
**project** (Project)

**abstractmethod process**(*state*, *, *block=None*, **kwargs*)

**Return type**
ResultType

**Parameters**

- **state** (StateType)
- **block** (*BlockType | None*)

**lift**(*state*)

**Return type**
BlockType

**Parameters**
**state** (StateType)

**static sp_offset**(*bits*, *offset*)

**Return type**
BV

**Parameters**

- **bits** (*int*)
- **offset** (*int*)

**static extract_offset_to_sp**(*spoffset_expr*)

Extract the offset to the original stack pointer.

**Parameters**
**spoffset_expr** (Base) – The claripy AST to parse.

**Return type**
int | None

**Returns**
The offset to the original stack pointer, or None if *spoffset_expr* is not a supported type of SpOffset expression.

**class** angr.engines.light.**SimEngineLightAIL**

Bases: *SimEngineLight*[StateType, DataType_co, Block, ResultType], Generic[StateType, DataType_co, StmtDataType, ResultType]

A mixin for doing static analysis on AIL

**__init__**(**args*, ***kwargs*)

**process**(*state*, ***, *block=None*, *whitelist=None*, ***kwargs*)

**Return type**
ResultType

**Parameters**

- **state** (StateType)
- **block** (*ailment.Block | None*)
- **whitelist** (*set[int] | None*)

**class** angr.engines.light.**SimEngineLightVEX**

Bases: *SimEngineLight*[StateType, DataType_co, *Block*, ResultType], Generic[StateType, DataType_co, ResultType, StmtDataType]

A mixin for doing static analysis on VEX

**tyenv:** IRTypeEnv

**static unop_handler**(*f*)

**Return type**
Callable[[, Unop], DataType_co]

**Parameters**
**f** (*Callable[[T, pyvex.expr.Unop], DataType_co]*)

**static binop_handler**(*f*)

**Return type**
Callable[[, Binop], DataType_co]

**Parameters**
**f** (*Callable[[T, pyvex.expr.Binop], DataType_co]*)

**static binopv_handler**(*f*)

**Return type**
Callable[[, int, int, Binop], DataType_co]

**Parameters**
**f** (*Callable[[T, int, int, pyvex.expr.Binop], DataType_co]*)

**static triop_handler**(*f*)

**Return type**
Callable[[, Triop], DataType_co]

**Parameters**
**f** (*Callable[[T, pyvex.expr.Triop], DataType_co]*)

**static qop_handler**(*f*)

**Return type**
Callable[[, Qop], DataType_co]

**Parameters**
**f** (*Callable[[T, pyvex.expr.Qop], DataType_co]*)

**static ccall_handler**(*f*)

**Return type**
Callable[[, CCall], DataType_co]

**Parameters**
**f** (Callable[[T, *pyvex.expr.CCall*], DataType_co])

**static dirty_handler**(*f*)

**Return type**
Callable[[, Dirty], StmtDataType]

**Parameters**
**f** (Callable[[T, *pyvex.stmt.Dirty*], StmtDataType])

**__init__**(**args*, ***kwargs*)

**process**(*state*, *, *block=None*, *whitelist=None*, ***kwargs*)

**Return type**
ResultType

**Parameters**

- **state** (StateType)
- **block** (Block | *None*)
- **whitelist** (*set[int]* | *None*)

**class** angr.engines.light.**SimEngineNoexprAIL**

Bases: *SimEngineLightAIL*[StateType, Optional[DataType_co], StmtDataType, ResultType], Generic[StateType, DataType_co, StmtDataType, ResultType]

A base class of SimEngineLightAIL that has default handlers for expressions if they just need to return None, so you don't have to implement every single expression handler as `return None`.

**class** angr.engines.light.**SimEngineNostmtAIL**

Bases: *SimEngineLightAIL*[StateType, DataType_co, Optional[StmtDataType], ResultType], Generic[StateType, DataType_co, StmtDataType, ResultType]

A base class of SimEngineLightAIL that has default handlers for statements if they just need to return None, so you don't have to implement every single statement handler as `return None`.

**class** angr.engines.light.**SimEngineNostmtVEX**

Bases: *SimEngineLightVEX*[StateType, DataType_co, ResultType, None], Generic[StateType, DataType_co, ResultType]

A base class of SimEngineLightVEX that has default handlers for statements if they just need to return None, so you don't have to implement every single statement handler as `return None`.

**class** angr.engines.light.**SpOffset**

Bases: *RegisterOffset*

**__init__**(*bits*, *offset*, *is_base=False*)

**is_base**

### Submodules

*data*
*engine*

### angr.engines.light.data

class angr.engines.light.data.**ArithmeticExpression**

Bases: object

**Add = 0**

**Sub = 1**

**Or = 2**

**And = 4**

**RShift = 8**

**LShift = 16**

**Mul = 32**

**Xor = 64**

**CONST_TYPES = (<class 'int'>, <class 'angr.ailment.expression.Const'>)**

**__init__**(*op*, *operands*)

**op**

**operands**

**static try_unpack_const**(*expr*)

class angr.engines.light.data.**RegisterOffset**

Bases: object

**__init__**(*bits*, *reg*, *offset*)

**reg**

**offset**

**property bits**

**property symbolic**

class angr.engines.light.data.**SpOffset**

Bases: *RegisterOffset*

**__init__**(*bits*, *offset*, *is_base=False*)

**is_base**

### angr.engines.light.engine

class angr.engines.light.engine.**BlockProtocol**

Bases: Protocol

The minimum protocol that a block an engine can process should adhere to. Requires just an addr attribute.

**addr:** int

**__init__**(**args*, ***kwargs*)

class angr.engines.light.engine.**IRTop**

Bases: IRExpr

A dummy IRExpr used for intra-engine communication and code-reuse.

**__init__**(*ty*)

**Parameters**
**ty** (*str*)

**result_type**(*tyenv*)

class angr.engines.light.engine.**SimEngineLight**

Bases: *SimEngine*[StateType, ResultType], Generic[StateType, DataType_co, BlockType, ResultType]

A full-featured engine base class, suitable for static analysis

**block:** BlockType

**state:** StateType

**stmt_idx:** int

**ins_addr:** int

**tmps:** dict[int, DataType_co]

**__init__**(*project*, *logger=None*)

**Parameters**
**project** (Project)

**abstractmethod process**(*state*, *, *block=None*, ***kwargs*)

**Return type**
ResultType

**Parameters**

- **state** (StateType)
- **block** (*BlockType | None*)

**lift**(*state*)

**Return type**
BlockType

**Parameters**
**state** (StateType)

**static sp_offset**(*bits*, *offset*)

**Return type**
BV

**Parameters**

- **bits** (*int*)
- **offset** (*int*)

**static extract_offset_to_sp**(*spoffset_expr*)

Extract the offset to the original stack pointer.

**Parameters**
**spoffset_expr** (Base) – The claripy AST to parse.

**Return type**
int | None

**Returns**
The offset to the original stack pointer, or None if *spoffset_expr* is not a supported type of SpOffset expression.

angr.engines.light.engine.**longest_prefix_lookup**[*T*](*haystack*, *mapping*)

**Return type**
Optional[T]

**Parameters**

- **haystack** (*str*)
- **mapping** (*dict[str, T]*)

**class** angr.engines.light.engine.**SimEngineLightVEX**

Bases: *SimEngineLight*[StateType, DataType_co, *Block*, ResultType], Generic[StateType, DataType_co, ResultType, StmtDataType]

A mixin for doing static analysis on VEX

**tyenv:** IRTypeEnv

**static unop_handler**(*f*)

**Return type**
Callable[[, Unop], DataType_co]

**Parameters**
**f** (Callable[[T, *pyvex.expr.Unop*], DataType_co])

**static binop_handler**(*f*)

**Return type**
Callable[[, Binop], DataType_co]

**Parameters**
**f** (Callable[[T, *pyvex.expr.Binop*], DataType_co])

**static binopv_handler**(*f*)

**Return type**
Callable[[, int, int, Binop], DataType_co]

**Parameters**
**f** (Callable[[T, int, int, pyvex.expr.Binop], DataType_co])

**static triop_handler**(*f*)

**Return type**
Callable[[, Triop], DataType_co]

**Parameters**
**f** (Callable[[T, pyvex.expr.Triop], DataType_co])

**static qop_handler**(*f*)

**Return type**
Callable[[, Qop], DataType_co]

**Parameters**
**f** (Callable[[T, pyvex.expr.Qop], DataType_co])

**static ccall_handler**(*f*)

**Return type**
Callable[[, CCall], DataType_co]

**Parameters**
**f** (Callable[[T, pyvex.expr.CCall], DataType_co])

**static dirty_handler**(*f*)

**Return type**
Callable[[, Dirty], StmtDataType]

**Parameters**
**f** (Callable[[T, pyvex.stmt.Dirty], StmtDataType])

**__init__**(**args*, ***kwargs*)

**process**(*state*, *, *block=None*, *whitelist=None*, ***kwargs*)

**Return type**
ResultType

**Parameters**

- **state** (StateType)
- **block** (Block | None)
- **whitelist** (set[int] | None)

**class** angr.engines.light.engine.**SimEngineNostmtVEX**

Bases: SimEngineLightVEX[StateType, DataType_co, ResultType, None], Generic[StateType, DataType_co, ResultType]

A base class of SimEngineLightVEX that has default handlers for statements if they just need to return None, so you don't have to implement every single statement handler as `return None`.

**class** angr.engines.light.engine.**SimEngineLightAIL**

Bases: SimEngineLight[StateType, DataType_co, Block, ResultType], Generic[StateType, DataType_co, StmtDataType, ResultType]

A mixin for doing static analysis on AIL

**__init__**(**args*, ***kwargs*)

**process**(*state*, *, *block=None*, *whitelist=None*, ***kwargs*)

**Return type**
ResultType

**Parameters**

- **state** (StateType)
- **block** (*ailment.Block | None*)
- **whitelist** (*set[int] | None*)

**class** angr.engines.light.engine.**SimEngineNostmtAIL**

Bases: *SimEngineLightAIL*[StateType, DataType_co, Optional[StmtDataType], ResultType], Generic[StateType, DataType_co, StmtDataType, ResultType]

A base class of SimEngineLightAIL that has default handlers for statements if they just need to return None, so you don't have to implement every single statement handler as `return None`.

**class** angr.engines.light.engine.**SimEngineNoexprAIL**

Bases: *SimEngineLightAIL*[StateType, Optional[DataType_co], StmtDataType, ResultType], Generic[StateType, DataType_co, StmtDataType, ResultType]

A base class of SimEngineLightAIL that has default handlers for expressions if they just need to return None, so you don't have to implement every single expression handler as `return None`.

### 10.15.7 angr.engines.pcode

**class** angr.engines.pcode.**HeavyPcodeMixin**

Bases: *SuccessorsEngine*, *PcodeLifterEngineMixin*, *PcodeEmulatorMixin*

Execution engine based on P-code, Ghidra's IR.

Responds to the following parameters to the step stack:

- irsb: The P-Code IRSB object to use for execution. If not provided one will be lifted.
- skip_stmts: The number of statements to skip in processing
- last_stmt: Do not execute any statements after this statement
- thumb: Whether the block should be force to be lifted in ARM's THUMB mode. (FIXME)
- **extra_stop_points:**
  An extra set of points at which to break basic blocks
- insn_bytes: A string of bytes to use for the block instead of the project.
- size: The maximum size of the block, in bytes.
- num_inst: The maximum number of instructions.

**__init__**(**args*, ***kwargs*)

angr.engines.pcode.**register_pcode_arch_default_cc**(*arch*)

**Parameters**
**arch** (*ArchPcode*)

### Submodules

behavior
cc
emulate
engine
lifter

### angr.engines.pcode.behavior

angr.engines.pcode.behavior.**make_bv_sizes_equal**(*bv1*, *bv2*, *zero_ext=False*)

Makes two BVs equal in length through sign extension.

**Return type**
tuple[BV, BV]

**Parameters**

- **bv1** (*BV*)
- **bv2** (*BV*)
- **zero_ext** (*bool*)

**class** angr.engines.pcode.behavior.**OpBehavior**

Bases: object

Base class for all operation behaviors.

**__init__**(*opcode*, *is_unary*, *is_special=False*)

**Parameters**

- **opcode** (*OpCode*)
- **is_unary** (*bool*)
- **is_special** (*bool*)

**Return type**
None

**opcode:** OpCode

**is_unary:** bool

**is_special:** bool

**evaluate_unary**(*size_out*, *size_in*, *in1*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)
- **in2** (*BV*)

**static generic_compare**(*args*, *comparison*)

**Return type**
BV

**Parameters**

- **args** (*Iterable[BV]*)
- **comparison** (*Callable[[BV, BV], BV]*)

**classmethod booleanize**(*in1*)

Reduce input BV to a single bit of truth: out <- 1 if (in1 != 0) else 0.

**Return type**
BV

**Parameters**
**in1** (*BV*)

**class** angr.engines.pcode.behavior.**OpBehaviorCopy**

Bases: *OpBehavior*

Behavior for the COPY operation.

**__init__**()

**evaluate_unary**(*size_out*, *size_in*, *in1*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

**class** angr.engines.pcode.behavior.**OpBehaviorEqual**

Bases: *OpBehavior*

Behavior for the INT_EQUAL operation.

__init__()

evaluate_binary(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)
- **in2** (*BV*)

is_special: bool

is_unary: bool

opcode: OpCode

class angr.engines.pcode.behavior.**OpBehaviorNotEqual**

Bases: *OpBehavior*

Behavior for the INT_NOTEQUAL operation.

__init__()

evaluate_binary(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)
- **in2** (*BV*)

is_special: bool

is_unary: bool

opcode: OpCode

class angr.engines.pcode.behavior.**OpBehaviorIntSless**

Bases: *OpBehavior*

Behavior for the INT_SLESS operation.

__init__()

evaluate_binary(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)

- **size_in** (*int*)
- **in1** (*BV*)
- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorIntSlessEqual**

Bases: *OpBehavior*

Behavior for the INT_SLESSEQUAL operation.

**__init__**()

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)
- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorIntLess**

Bases: *OpBehavior*

Behavior for the INT_LESS operation.

**__init__**()

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)
- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

**class** angr.engines.pcode.behavior.**OpBehaviorIntLessEqual**

Bases: *OpBehavior*

Behavior for the INT_LESSEQUAL operation.

**__init__**()

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)
- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

**class** angr.engines.pcode.behavior.**OpBehaviorIntZext**

Bases: *OpBehavior*

Behavior for the INT_ZEXT operation.

**__init__**()

**evaluate_unary**(*size_out*, *size_in*, *in1*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

**class** angr.engines.pcode.behavior.**OpBehaviorIntSext**

Bases: *OpBehavior*

Behavior for the INT_SEXT operation.

**__init__**()

**evaluate_unary**(*size_out*, *size_in*, *in1*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

**class** angr.engines.pcode.behavior.**OpBehaviorIntAdd**

Bases: *OpBehavior*

Behavior for the INT_ADD operation.

**__init__**()

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)
- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

**class** angr.engines.pcode.behavior.**OpBehaviorIntSub**

Bases: *OpBehavior*

Behavior for the INT_SUB operation.

**__init__**()

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)

- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorIntCarry**

Bases: *OpBehavior*

Behavior for the INT_CARRY operation.

**__init__**()

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)
- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorIntScarry**

Bases: *OpBehavior*

Behavior for the INT_SCARRY operation.

**__init__**()

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)
- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorIntSborrow**

Bases: *OpBehavior*

Behavior for the INT_SBORROW operation.

**__init__**()

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)
- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorInt2Comp**

Bases: *OpBehavior*

Behavior for the INT_2COMP operation.

**__init__**()

**evaluate_unary**(*size_out*, *size_in*, *in1*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorIntNegate**

Bases: *OpBehavior*

Behavior for the INT_NEGATE operation.

**__init__**()

**evaluate_unary**(*size_out*, *size_in*, *in1*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

**class** angr.engines.pcode.behavior.**OpBehaviorIntXor**

Bases: *OpBehavior*

Behavior for the INT_XOR operation.

**__init__**()

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)
- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

**class** angr.engines.pcode.behavior.**OpBehaviorIntAnd**

Bases: *OpBehavior*

Behavior for the INT_AND operation.

**__init__**()

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)

- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

**class** angr.engines.pcode.behavior.**OpBehaviorIntOr**

Bases: *OpBehavior*

Behavior for the INT_OR operation.

**__init__**()

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)
- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

**class** angr.engines.pcode.behavior.**OpBehaviorIntLeft**

Bases: *OpBehavior*

Behavior for the INT_LEFT operation.

**__init__**()

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)
- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorIntRight**

Bases: *OpBehavior*

Behavior for the INT_RIGHT operation.

**__init__**()

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)
- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorIntSright**

Bases: *OpBehavior*

Behavior for the INT_SRIGHT operation.

**__init__**()

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)
- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorIntMult**

Bases: *OpBehavior*

Behavior for the INT_MULT operation.

**__init__**()

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)
- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

**class** angr.engines.pcode.behavior.**OpBehaviorIntDiv**

Bases: *OpBehavior*

Behavior for the INT_DIV operation.

**__init__**()

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)
- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

**class** angr.engines.pcode.behavior.**OpBehaviorIntSdiv**

Bases: *OpBehavior*

Behavior for the INT_SDIV operation.

**__init__**()

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)

- **in1** (*BV*)
- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorIntRem**

Bases: *OpBehavior*

Behavior for the INT_REM operation.

**__init__**()

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)
- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorIntSrem**

Bases: *OpBehavior*

Behavior for the INT_SREM operation.

**__init__**()

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)
- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorBoolNegate**

Bases: *OpBehavior*

Behavior for the BOOL_NEGATE operation.

**__init__**()

**evaluate_unary**(*size_out*, *size_in*, *in1*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorBoolXor**

Bases: *OpBehavior*

Behavior for the BOOL_XOR operation.

**__init__**()

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)
- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorBoolAnd**

Bases: *OpBehavior*

Behavior for the BOOL_AND operation.

**__init__**()

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)
- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

**class** angr.engines.pcode.behavior.**OpBehaviorBoolOr**

Bases: *OpBehavior*

Behavior for the BOOL_OR operation.

**__init__**()

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)
- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

**class** angr.engines.pcode.behavior.**OpBehaviorFloatEqual**

Bases: *OpBehavior*

Behavior for the FLOAT_EQUAL operation.

**__init__**()

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorFloatNotEqual**

Bases: *OpBehavior*

Behavior for the FLOAT_NOTEQUAL operation.

**__init__**()

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorFloatLess**

Bases: *OpBehavior*

Behavior for the FLOAT_LESS operation.

**__init__**()

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorFloatLessEqual**

Bases: *OpBehavior*

Behavior for the FLOAT_LESSEQUAL operation.

**__init__**()

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorFloatNan**

Bases: *OpBehavior*

Behavior for the FLOAT_NAN operation.

**__init__**()

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorFloatAdd**

Bases: *OpBehavior*

Behavior for the FLOAT_ADD operation.

**__init__**()

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

**class** angr.engines.pcode.behavior.**OpBehaviorFloatDiv**

Bases: *OpBehavior*

Behavior for the FLOAT_DIV operation.

**__init__**()

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

**class** angr.engines.pcode.behavior.**OpBehaviorFloatMult**

Bases: *OpBehavior*

Behavior for the FLOAT_MULT operation.

**__init__**()

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

**class** angr.engines.pcode.behavior.**OpBehaviorFloatSub**

Bases: *OpBehavior*

Behavior for the FLOAT_SUB operation.

**__init__**()

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

**class** angr.engines.pcode.behavior.**OpBehaviorFloatNeg**

Bases: *OpBehavior*

Behavior for the FLOAT_NEG operation.

**__init__**()

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

**class** angr.engines.pcode.behavior.**OpBehaviorFloatAbs**

Bases: *OpBehavior*

Behavior for the FLOAT_ABS operation.

**__init__**()

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorFloatSqrt**

Bases: *OpBehavior*

Behavior for the FLOAT_SQRT operation.

**__init__**()

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorFloatInt2Float**

Bases: *OpBehavior*

Behavior for the FLOAT_INT2FLOAT operation.

**__init__**()

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorFloatFloat2Float**

Bases: *OpBehavior*

Behavior for the FLOAT_FLOAT2FLOAT operation.

**__init__**()

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorFloatTrunc**

Bases: *OpBehavior*

Behavior for the FLOAT_TRUNC operation.

**__init__**()

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorFloatCeil**

Bases: *OpBehavior*

Behavior for the FLOAT_CEIL operation.

**__init__**()

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorFloatFloor**

Bases: *OpBehavior*

Behavior for the FLOAT_FLOOR operation.

**__init__**()

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorFloatRound**

Bases: *OpBehavior*

Behavior for the FLOAT_ROUND operation.

**__init__**()

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorPiece**

Bases: *OpBehavior*

Behavior for the PIECE operation.

**__init__**()

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

class angr.engines.pcode.behavior.**OpBehaviorSubpiece**

Bases: *OpBehavior*

Behavior for the SUBPIECE operation.

**__init__**()

**evaluate_binary**(*size_out*, *size_in*, *in1*, *in2*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)

- **in2** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

**class** angr.engines.pcode.behavior.**OpBehaviorPopcount**

Bases: *OpBehavior*

Behavior for the POPCOUNT operation.

**__init__**()

**evaluate_unary**(*size_out*, *size_in*, *in1*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

**class** angr.engines.pcode.behavior.**OpBehaviorLzcount**

Bases: *OpBehavior*

Behavior for the LZCOUNT operation.

**__init__**()

**evaluate_unary**(*size_out*, *size_in*, *in1*)

**Return type**
BV

**Parameters**

- **size_out** (*int*)
- **size_in** (*int*)
- **in1** (*BV*)

**is_special:** bool

**is_unary:** bool

**opcode:** OpCode

**class** angr.engines.pcode.behavior.**BehaviorFactory**

Bases: object

Returns the behavior object for a given opcode.

__init__()

get_behavior_for_opcode(*opcode*)

**Return type**
*OpBehavior*

**Parameters**
**opcode** (*OpCode*)

### angr.engines.pcode.cc

class angr.engines.pcode.cc.**SimCCPCodeBase**

Bases: *SimCC*

Base class for all pcode calling conventions.

LANGUAGE = None

classmethod ARCH()

class angr.engines.pcode.cc.**SimCCM68k**

Bases: *SimCCPCodeBase*

Default CC for M68k

LANGUAGE = '68000:BE:32:default'

**RETURN_ADDR**: *SimFunctionArgument* | None = <a0>

**RETURN_VAL**: *SimFunctionArgument* | None = <a2>

angr.engines.pcode.cc.**register_pcode_arch_default_cc**(*arch*)

**Parameters**

**arch** (*ArchPcode*)

### angr.engines.pcode.emulate

**class** angr.engines.pcode.emulate.**PcodeEmulatorMixin**

Bases: *SimEngine*

Mixin for p-code execution.

**__init__**(**args*, ***kwargs*)

**handle_pcode_block**(*irsb*)

Execute a single P-Code IRSB.

**Parameters**
**irsb** (*IRSB*) – Block to be executed.

**Return type**
None

### angr.engines.pcode.engine

**class** angr.engines.pcode.engine.**HeavyPcodeMixin**

Bases: *SuccessorsEngine*, *PcodeLifterEngineMixin*, *PcodeEmulatorMixin*

Execution engine based on P-code, Ghidra's IR.

Responds to the following parameters to the step stack:

- irsb: The P-Code IRSB object to use for execution. If not provided one will be lifted.
- skip_stmts: The number of statements to skip in processing
- last_stmt: Do not execute any statements after this statement
- thumb: Whether the block should be force to be lifted in ARM's THUMB mode. (FIXME)
- **extra_stop_points:**
  An extra set of points at which to break basic blocks
- insn_bytes: A string of bytes to use for the block instead of the project.
- size: The maximum size of the block, in bytes.
- num_inst: The maximum number of instructions.

**__init__**(**args*, ***kwargs*)

### angr.engines.pcode.lifter

**class** angr.engines.pcode.lifter.**ExitStatement**

Bases: object

This class exists to ease compatibility with CFGFast's processing of exit_statements. See _scan_irsb method.

**__init__**(*dst*, *jumpkind*)

**Parameters**
- **dst** (*int | None*)
- **jumpkind** (*str*)

**dst:** int | None

**jumpkind:** str

class angr.engines.pcode.lifter.**PcodeDisassemblerBlock**

Bases: *DisassemblerBlock*

Helper class to represent a block of disassembled target architecture instructions

**addr**

**arch**

**insns**

**thumb**

class angr.engines.pcode.lifter.**PcodeDisassemblerInsn**

Bases: *DisassemblerInsn*

Helper class to represent a disassembled target architecture instruction

**__init__**(*pcode_insn*)

**property size:** int

**property address:** int

**property mnemonic:** str

**property op_str:** str

class angr.engines.pcode.lifter.**IRSB**

Bases: object

IRSB stands for *Intermediate Representation Super-Block*. An IRSB in is a single-entry, multiple-exit code block.

**Variables**

- **arch** (archinfo.Arch) – The architecture this block is lifted under
- **statements** (list of IRStmt) – The statements in this block
- **next** (IRExpr) – The expression for the default exit target of this block
- **offsIP** (*int*) – The offset of the instruction pointer in the VEX guest state
- **stmts_used** (*int*) – The number of statements in this IRSB
- **jumpkind** (*str*) – The type of this block's default jump (call, boring, syscall, etc) as a VEX enum string
- **direct_next** (*bool*) – Whether this block ends with a direct (not indirect) jump or branch
- **size** (*int*) – The size of this block in bytes
- **addr** (*int*) – The address of this basic block, i.e. the address in the first IMark

**MAX_EXITS = 400**

**MAX_DATA_REFS = 2000**

**__init__**(*data*, *mem_addr*, *arch*, *max_inst=None*, *max_bytes=None*, *bytes_offset=0*, *traceflags=0*, *opt_level=1*, *num_inst=None*, *num_bytes=None*, *strict_block_end=False*, *skip_stmts=False*, *collect_data_refs=False*)

**Parameters**

- **data** (str | bytes | None) – The bytes to lift. Can be either a string of bytes or a cffi buffer object. You may also pass None to initialize an empty IRSB.
- **mem_addr** (int) – The address to lift the data at.
- **arch** (Arch) – The architecture to lift the data as.
- **max_inst** (int | None) – The maximum number of instructions to lift. (See note below)
- **max_bytes** (int | None) – The maximum number of bytes to use.
- **num_inst** (int | None) – Replaces max_inst if max_inst is None. If set to None as well, no instruction limit is used.
- **num_bytes** (int | None) – Replaces max_bytes if max_bytes is None. If set to None as well, no byte limit is used.
- **bytes_offset** (int) – The offset into *data* to start lifting at. Note that for ARM THUMB mode, both *mem_addr* and *bytes_offset* must be odd (typically *bytes_offset* is set to 1).
- **traceflags** (int) – Unused by P-Code lifter
- **opt_level** (int) – Unused by P-Code lifter
- **strict_block_end** (bool) – Unused by P-Code lifter
- **skip_stmts** (*bool*)
- **collect_data_refs** (*bool*)

**Return type**
None

> **Note**
>
> Explicitly specifying the number of instructions to lift (*max_inst*) may not always work exactly as expected. For example, on MIPS, it is meaningless to lift a branch or jump instruction without its delay slot. VEX attempts to Do The Right Thing by possibly decoding fewer instructions than requested. Specifically, this means that lifting a branch or jump on MIPS as a single instruction (*max_inst=1*) will result in an empty IRSB, and subsequent attempts to run this block will raise *SimIRSBError('Empty IRSB passed to SimIRSB.')*.

> **Note**
>
> If no instruction and byte limit is used, the lifter will continue lifting the block until the block ends properly or until it runs out of data to lift.

**addr:** int

**arch:** Arch

**behaviors:** *BehaviorFactory* | None

**data_refs:** Sequence

**const_vals:** Sequence

**default_exit_target:** Any

**jumpkind:** str | None

**next:** IRExpr | None

**static empty_block**(*arch*, *addr*, *statements=None*, *nxt=None*, *tyenv=None*, *jumpkind=None*, *direct_next=None*, *size=None*)

**Return type**
*IRSB*

**Parameters**

- **arch** (*Arch*)
- **addr** (*int*)
- **statements** (*Sequence | None*)
- **nxt** (*int | None*)
- **jumpkind** (*str | None*)
- **direct_next** (*bool | None*)
- **size** (*int | None*)

**property has_statements:** bool

**property exit_statements:** Sequence[tuple[int, int, *ExitStatement*]]

**copy**()

Copy by creating an empty IRSB and then filling in the leftover attributes. Copy is made as deep as possible

**Return type**
*IRSB*

**extend**(*extendwith*)

Appends an irsb to the current irsb. The irsb that is appended is invalidated. The appended irsb's jumpkind and default exit are used. :type extendwith: *IRSB* :param extendwith: The IRSB to append to this IRSB

**Return type**
*IRSB*

**Parameters**
**extendwith** (IRSB)

**invalidate_direct_next**()

**Return type**
None

**pp**()

Pretty-print the IRSB to stdout.

**Return type**
None

**property tyenv**

**property stmts_used:** int

**property offsIP:** int | None

**property direct_next:** bool

**property expressions**

Return an iterator of all expressions contained in the IRSB.

**property instructions:** int

The number of instructions in this block

**property instruction_addresses:** Sequence[int]

Addresses of instructions in this block.

**property size:** int

The size of this block, in bytes

**property operations**

A list of all operations done by the IRSB, as libVEX enum names

**property all_constants**

Returns all constants in the block (including incrementing of the program counter) as pyvex.const.IRConst.

**property constants**

The constants (excluding updates of the program counter) in the IRSB as pyvex.const.IRConst.

**property constant_jump_targets**

A set of the static jump targets of the basic block.

**property constant_jump_targets_and_jumpkinds**

A dict of the static jump targets of the basic block to their jumpkind.

**property is_noop_block:** bool

Returns True if this block is a no-op block (i.e. it has no instructions and no jumps).

**property statements:** list

**property disassembly:** *PcodeDisassemblerBlock*

**class** angr.engines.pcode.lifter.**Lifter**

Bases: object

A lifter is a class of methods for processing a block.

**Variables**

- **data** (str | bytes | None) – The bytes to lift as either a python string of bytes or a cffi buffer object.
- **bytes_offset** (int | None) – The offset into *data* to start lifting at.
- **max_bytes** (int | None) – The maximum number of bytes to lift. If set to None, no byte limit is used.
- **max_inst** (int | None) – The maximum number of instructions to lift. If set to None, no instruction limit is used.
- **opt_level** (int) – Unused by P-Code lifter
- **traceflags** (int | None) – Unused by P-Code lifter
- **allow_arch_optimizations** (bool | None) – Unused by P-Code lifter
- **strict_block_end** (bool | None) – Unused by P-Code lifter

- **skip_stmts** (bool) – Unused by P-Code lifter

REQUIRE_DATA_C = False

REQUIRE_DATA_PY = False

__init__(*arch*, *addr*)

**Parameters**

- **arch** (*Arch*)
- **addr** (*int*)

arch: Arch

addr: int

data: str | bytes | None

bytes_offset: int | None

opt_level: int

traceflags: int | None

allow_arch_optimizations: bool | None

strict_block_end: bool | None

collect_data_refs: bool

max_inst: int | None

max_bytes: int | None

skip_stmts: bool

irsb: *IRSB*

lift()

Lifts the data using the information passed into _lift. Should be overridden in child classes.

Should set the lifted IRSB to self.irsb. If a lifter raises a LiftingException on the data, this signals that the lifter cannot lift this data and arch and the lifter is skipped. If a lifter can lift any amount of data, it should lift it and return the lifted block with a jumpkind of Ijk_NoDecode, signalling to pyvex that other lifters should be used on the undecodable data.

**Return type**
None

angr.engines.pcode.lifter.**lift**(*data*, *addr*, *arch*, *max_bytes=None*, *max_inst=None*, *bytes_offset=0*, *opt_level=1*, *traceflags=0*, *strict_block_end=True*, *inner=False*, *skip_stmts=False*, *collect_data_refs=False*, *block_lifter=None*)

Lift machine code in *data* to a P-code IRSB.

If a lifter raises a LiftingException on the data, it is skipped. If it succeeds and returns a block with a jumpkind of Ijk_NoDecode, all of the lifters are tried on the rest of the data and if they work, their output is appended to the first block.

**Parameters**

- **arch** (Arch) – The arch to lift the data as.

- **addr** (int) – The starting address of the block. Effects the IMarks.
- **data** (str | bytes | None) – The bytes to lift as either a python string of bytes or a cffi buffer object.
- **max_bytes** (int | None) – The maximum number of bytes to lift. If set to None, no byte limit is used.
- **max_inst** (int | None) – The maximum number of instructions to lift. If set to None, no instruction limit is used.
- **bytes_offset** (int) – The offset into *data* to start lifting at.
- **opt_level** (int) – Unused by P-Code lifter
- **traceflags** (int) – Unused by P-Code lifter
- **block_lifter** (*PcodeBasicBlockLifter* | None) – The basic block lifter, and therefore the Sleigh context, to decode with. A private one is created when it is not given.
- **strict_block_end** (*bool*)
- **inner** (*bool*)
- **skip_stmts** (*bool*)
- **collect_data_refs** (*bool*)

**Return type**
*IRSB*

**Note**

Explicitly specifying the number of instructions to lift (*max_inst*) may not always work exactly as expected. For example, on MIPS, it is meaningless to lift a branch or jump instruction without its delay slot. VEX attempts to Do The Right Thing by possibly decoding fewer instructions than requested. Specifically, this means that lifting a branch or jump on MIPS as a single instruction (*max_inst=1*) will result in an empty IRSB, and subsequent attempts to run this block will raise *SimIRSBError('Empty IRSB passed to SimIRSB.')*.

**Note**

If no instruction and byte limit is used, the lifter will continue lifting the block until the block ends properly or until it runs out of data to lift.

**class** angr.engines.pcode.lifter.**PcodeBasicBlockLifter**

Bases: object

Lifts basic blocks to P-code

Sleigh records context variables per address, so an instance must stay with one binary. See *angr.project.Project.pcode_block_lifter()*.

**__init__**(*arch*)

**Parameters**
**arch** (*Arch*)

**arch:** Arch

**context:** *Context*

**behaviors:** *BehaviorFactory*

**lift**(*irsb*, *baseaddr*, *data*, *bytes_offset=0*, *max_bytes=None*, *max_inst=None*, *branch_delay_slot=False*, *is_sparc32=False*)

**Return type**
None

**Parameters**

- **irsb** (IRSB)
- **baseaddr** (*int*)
- **data** (bytes | *bytearray*)
- **bytes_offset** (*int*)
- **max_bytes** (*int* | *None*)
- **max_inst** (*int* | *None*)
- **branch_delay_slot** (*bool*)
- **is_sparc32** (*bool*)

**class** angr.engines.pcode.lifter.**PcodeLifter**

Bases: *Lifter*

Handles calling into pypcode to lift a block

**__init__**(*arch*, *addr*, *block_lifter*)

**Parameters**

- **arch** (*Arch*)
- **addr** (*int*)
- **block_lifter** (PcodeBasicBlockLifter)

**block_lifter:** *PcodeBasicBlockLifter*

**class** angr.engines.pcode.lifter.**PcodeLifterEngineMixin**

Bases: *SimEngine*

Lifter mixin to lift from machine code to P-Code.

**__init__**(*project=None*, *use_cache=None*, *cache_size=50000*, *default_opt_level=1*, *selfmodifying_code=None*, *single_step=False*, *default_strict_block_end=False*, ***kwargs*)

**Parameters**

- **use_cache** (*bool* | *None*)
- **cache_size** (*int*)
- **default_opt_level** (*int*)
- **selfmodifying_code** (*bool* | *None*)
- **single_step** (*bool*)
- **default_strict_block_end** (*bool*)

clear_cache()

**Return type**
None

lift_vex(*addr=None*, *state=None*, *clemory=None*, *insn_bytes=None*, *arch=None*, *size=None*, *num_inst=None*, *traceflags=0*, *thumb=False*, *extra_stop_points=None*, *opt_level=None*, *strict_block_end=None*, *skip_stmts=False*, *collect_data_refs=False*, *load_from_ro_regions=False*, *cross_insn_opt=None*, *const_prop=None*)

Temporary compatibility interface for integration with block code.

**Return type**
*IRSB*

**Parameters**

- **addr** (*int | None*)
- **state** (SimState | *None*)
- **clemory** (*Clemory | ClemoryReadOnlyView | None*)
- **insn_bytes** (bytes | *None*)
- **arch** (*Arch | None*)
- **size** (*int | None*)
- **num_inst** (*int | None*)
- **traceflags** (*int*)
- **thumb** (*bool*)
- **extra_stop_points** (*Iterable[int] | None*)
- **opt_level** (*int | None*)
- **strict_block_end** (*bool | None*)
- **skip_stmts** (*bool*)
- **collect_data_refs** (*bool*)
- **load_from_ro_regions** (*bool*)
- **cross_insn_opt** (*bool | None*)
- **const_prop** (*bool | None*)

lift_pcode(*addr=None*, *state=None*, *clemory=None*, *insn_bytes=None*, *arch=None*, *size=None*, *num_inst=None*, *traceflags=0*, *thumb=False*, *extra_stop_points=None*, *opt_level=None*, *strict_block_end=None*, *skip_stmts=False*, *collect_data_refs=False*, *load_from_ro_regions=False*, *cross_insn_opt=None*, *const_prop=None*)

Lift an IRSB.

There are many possible valid sets of parameters. You at the very least must pass some source of data, some source of an architecture, and some source of an address.

Sources of data in order of priority: insn_bytes, clemory, state

Sources of an address, in order of priority: addr, state

Sources of an architecture, in order of priority: arch, clemory, state

**Parameters**

- **state** (*SimState* | None) – A state to use as a data source.
- **clemory** (Clemory | ClemoryReadOnlyView | None) – A cle.memory.Clemory object to use as a data source.
- **addr** (int | None) – The address at which to start the block.
- **thumb** (bool) – Whether the block should be lifted in ARM's THUMB mode.
- **opt_level** (int | None) – Unused for P-Code lifter
- **insn_bytes** (bytes | None) – A string of bytes to use as a data source.
- **size** (int | None) – The maximum size of the block, in bytes.
- **num_inst** (int | None) – The maximum number of instructions.
- **traceflags** (int) – Unused by P-Code lifter
- **strict_block_end** (bool | None) – Unused by P-Code lifter
- **load_from_ro_regions** (bool) – Unused by P-Code lifter
- **arch** (*Arch* | *None*)
- **extra_stop_points** (*Iterable[int]* | *None*)
- **skip_stmts** (*bool*)
- **collect_data_refs** (*bool*)
- **cross_insn_opt** (*bool* | *None*)
- **const_prop** (*bool* | *None*)

**Return type**
*IRSB*

### 10.15.8 angr.engines.procedure

**class** angr.engines.procedure.**ProcedureMixin**

Bases: object

A mixin for SimEngine which adds the process_procedure method for calling a SimProcedure and adding its results to a SimSuccessors.

**process_procedure**(*state*, *successors*, *procedure*, *ret_to=None*, *arguments=None*, ***kwargs*)

**class** angr.engines.procedure.**ProcedureEngine**

Bases: *ProcedureMixin*, *SuccessorsEngine*

A SimEngine that you may use if you only care about processing SimProcedures. *Requires* the procedure kwarg to be passed to process.

### 10.15.9 angr.engines.soot

**class** angr.engines.soot.**SootMixin**

Bases: *SuccessorsEngine*, *ProcedureMixin*

Execution engine based on Soot.

**lift_soot**(*addr=None*, *the_binary=None*, ***kwargs*)

**get_unconstrained_simprocedure**()

**classmethod setup_callsite**(*state*, *args*, *ret_addr*, *ret_var=None*)

**static setup_arguments**(*state*, *args*)

**static prepare_return_state**(*state*, *ret_value=None*)

**static terminate_execution**(*statement*, *state*, *successors*)

**static prepare_native_return_state**(*native_state*)

Hook target for native function call returns.

Recovers and stores the return value from native memory and toggles the state, s.t. execution continues in the Soot engine.

### Submodules

classmethod from_field_id(*field_id*)

classmethod from_sootvalue(*soot_value*, *state*)

classmethod get_ref(*state*, *field_class_name*, *field_name*, *field_type*)

Resolve the field within the given state.

class angr.engines.soot.values.SimSootValue_StringRef

Bases: SimSootValue

__init__(*heap_alloc_id*)

id

type

classmethod from_sootvalue(*soot_value*, *state*)

**static new_string**(*state*, *value*)

Allocate and initialize a new string in the context of the state passed.

The method returns the reference to the newly allocated string

**Parameters**

- **state** (SimState) – angr state where we want to allocate the string
- **value** (*claripy.String*) – value of the string to initialize

**Returns**
SimSootValue_StringRef

**class** angr.engines.soot.values.**SimSootValue_ThisRef**

Bases: *SimSootValue*

**__init__**(*heap_alloc_id*, *type_*, *symbolic=False*)

**property id**

**set_field**(*state*, *field_name*, *field_type*, *field_value*)

Sets an instance field.

**Parameters**

- **state** (SimState) – angr state where we want to allocate the object attribute
- **field_name** (*str*) – name of the attribute
- **field_type** (*str*) – type of the attribute
- **field_value** (SimSootValue) – attribute's value

**get_field**(*state*, *field_name*, *field_type*)

Gets the value of an instance field.

**Parameters**

- **state** (SimState) – angr state where we want to allocate the object attribute
- **field_name** (*str*) – name of the attribute
- **field_type** (*str*) – type of the attribute

**store_field**(*state*, *field_name*, *field_type*, *value*)

Store a field of a given object, WITHOUT RESOLVING HIERARCHY

**Parameters**

- **state** (SimState) – angr state where we want to allocate the object attribute
- **field_name** (*str*) – name of the attribute
- **field_value** (SimSootValue) – attribute's value

**load_field**(*state*, *field_name*, *field_type*)

Load a field of a given object, without resolving HIERARCHY

**Parameters**

- **tastate** (SimState) – angr state where we want to load the object attribute
- **field_name** (*str*) – name of the attribute
- **field_type** (*str*) – type of the attribute

**classmethod from_sootvalue**(*soot_value*, *state*)

**classmethod new_object**(*state*, *type_*, *symbolic=False*, *init_object=False*, *init_class=False*)

Creates a new object reference.

**Parameters**

- **state** – State associated to the object.
- **type_** – Class of the object.
- **init_object** – Whether the objects initializer method should be run.
- **init_class** – Whether the class initializer method should be run.

**Returns**

Reference to the new object.

angr.engines.soot.values.**translate_value**(*value*, *state*)

**classmethod from_field_id**(*field_id*)

**classmethod from_sootvalue**(*soot_value*, *state*)

**classmethod get_ref**(*state*, *field_class_name*, *field_name*, *field_type*)

Resolve the field within the given state.

### angr.engines.soot.values.strref

class angr.engines.soot.values.strref.**SimSootValue_StringRef**

Bases: *SimSootValue*

**__init__**(*heap_alloc_id*)

**id**

**type**

**classmethod from_sootvalue**(*soot_value*, *state*)

**static new_string**(*state*, *value*)

Allocate and initialize a new string in the context of the state passed.

The method returns the reference to the newly allocated string

**Parameters**

- **state** (SimState) – angr state where we want to allocate the string
- **value** (*claripy.String*) – value of the string to initialize

**Returns**

SimSootValue_StringRef

### angr.engines.soot.values.thisref

**class** angr.engines.soot.values.thisref.**SimSootValue_ThisRef**

Bases: *SimSootValue*

**__init__**(*heap_alloc_id*, *type_*, *symbolic=False*)

**property id**

**set_field**(*state*, *field_name*, *field_type*, *field_value*)

Sets an instance field.

**Parameters**

- **state** (SimState) – angr state where we want to allocate the object attribute
- **field_name** (*str*) – name of the attribute
- **field_type** (*str*) – type of the attribute
- **field_value** (SimSootValue) – attribute's value

**get_field**(*state*, *field_name*, *field_type*)

Gets the value of an instance field.

**Parameters**

- **state** (SimState) – angr state where we want to allocate the object attribute
- **field_name** (*str*) – name of the attribute
- **field_type** (*str*) – type of the attribute

**store_field**(*state*, *field_name*, *field_type*, *value*)

Store a field of a given object, WITHOUT RESOLVING HIERARCHY

**Parameters**

- **state** (SimState) – angr state where we want to allocate the object attribute
- **field_name** (*str*) – name of the attribute
- **field_value** (SimSootValue) – attribute's value

**load_field**(*state*, *field_name*, *field_type*)

Load a field of a given object, without resolving HIERARCHY

**Parameters**

- **tastate** (SimState) – angr state where we want to load the object attribute
- **field_name** (*str*) – name of the attribute
- **field_type** (*str*) – type of the attribute

**classmethod from_sootvalue**(*soot_value*, *state*)

**classmethod new_object**(*state*, *type_*, *symbolic=False*, *init_object=False*, *init_class=False*)

Creates a new object reference.

**Parameters**

- **state** – State associated to the object.
- **type_** – Class of the object.
- **init_object** – Whether the objects initializer method should be run.
- **init_class** – Whether the class initializer method should be run.

**Returns**

Reference to the new object.

### 10.15.10 angr.engines.successors

**class** angr.engines.successors.**SimSuccessors**

Bases: object

This class serves as a categorization of all the kinds of result states that can come from a SimEngine run.

**Variables**

- **addr** (*int*) – The address at which execution is taking place, as a python int
- **initial_state** – The initial state for which execution produced these successors
- **engine** – The engine that produced these successors
- **sort** (str | None) – A string identifying the type of engine that produced these successors
- **processed** (*bool*) – Whether or not the processing succeeded
- **description** (*str*) – A textual description of the execution step

The successor states produced by this run are categorized into several lists:

**Variables**

- **artifacts** (*dict*) – Any analysis byproducts (for example, an IRSB) that were produced during execution
- **successors** (list[]) – The "normal" successors. IP may be symbolic, but must have reasonable number of solutions
- **unsat_successors** (list[]) – Any successor which is unsatisfiable after its guard condition is added.
- **all_successors** (list[]) – successors + unsat_successors

- **flat_successors** (list[]) – The normal successors, but any symbolic IPs have been concretized. There is one state in this list for each possible value an IP may be concretized to for each successor state.
- **unconstrained_successors** (list[]) – Any state for which during the flattening process we find too many solutions.

A more detailed description of the successor lists may be found here: https://docs.angr.io/core-concepts/simulation#simsuccessors

**__init__**(*addr*, *initial_state*)

**Parameters**

- **addr** (*int* | *SootAddressDescriptor* | *None*)
- **initial_state** (HeavyState | *None*)

**property is_empty**

**add_successor**(*state*, *target*, *guard*, *jumpkind*, *add_guard=True*, *exit_stmt_idx=None*, *exit_ins_addr=None*, *source=None*)

Add a successor state of the SimRun. This procedure stores method parameters into state.scratch, does some housekeeping, and calls out to helper functions to prepare the state and categorize it into the appropriate successor lists.

**Parameters**

- **state** (SimState) – The successor state.
- **target** – The target (of the jump/call/ret).
- **guard** – The guard expression.
- **jumpkind** (*str*) – The jumpkind (call, ret, jump, or whatnot).
- **add_guard** (*bool*) – Whether to add the guard constraint (default: True).
- **exit_stmt_idx** (*int*) – The ID of the exit statement, an integer by default. 'default' stands for the default exit, and None means it's not from a statement (for example, from a SimProcedure).
- **exit_ins_addr** (*int*) – The instruction pointer of this exit, which is an integer by default.
- **source** (*int*) – The source of the jump (i.e., the address of the basic block).

**type** angr.engines.successors.**HeavyState** = *SimState*[int | SootAddressDescriptor, claripy.ast.BV | SootAddressDescriptor]

**class** angr.engines.successors.**SuccessorsEngine**

Bases: *SimEngine*[, *SimSuccessors*]

A mixin for SimEngine which implements `process` to perform common operations related to symbolic execution and dispatches to a `process_successors` method to fill a SimSuccessors object with the results.

**__init__**(*project*)

**Parameters**

**project** (Project)

**process**(*state*, ***kwargs*)

Perform execution with a state.

You should only override this method in a subclass in order to provide the correct method signature and docstring. You should override the `_process` method to do your actual execution.

**Parameters**

- **state** () – The state with which to execute. This state will be copied before modification.
- **inline** – This is an inline execution. Do not bother copying the state.
- **force_addr** – Force execution to pretend that we're working at this concrete address

**Return type**
*SimSuccessors*

**Returns**
A SimSuccessors object categorizing the execution's successor states

**process_successors**(*successors*, ***kwargs*)

Implement this function to fill out the SimSuccessors object with the results of stepping state.

In order to implement a model where multiple mixins can potentially handle a request, a mixin may implement this method and then perform a super() call if it wants to pass on handling to the next mixin.

Keep in mind python's method resolution order when composing multiple classes implementing this method. In short: left-to-right, depth-first, but deferring any base classes which are shared by multiple subclasses (the merge point of a diamond pattern in the inheritance graph) until the last point where they would be encountered in this depth-first search. For example, if you have classes A, B(A), C(B), D(A), E(C, D), then the method resolution order will be E, C, B, D, A.

**Parameters**

- **state** – The state to manipulate
- **successors** (*SimSuccessors*) – The successors object to fill out
- **kwargs** – Any extra arguments. Do not fail if you are passed unexpected arguments.

### 10.15.11 angr.engines.syscall

**class** angr.engines.syscall.**SimEngineSyscall**

Bases: *SuccessorsEngine*, *ProcedureMixin*

A SimEngine mixin which adds a successors handling step that checks if a syscall was just requested and if so handles it as a step.

### 10.15.12 angr.engines.unicorn

**class** angr.engines.unicorn.**SimEngineUnicorn**

Bases: *SuccessorsEngine*

Concrete execution in the Unicorn Engine, a fork of qemu.

Responds to the following parameters in the step stack:

- step: How many basic blocks we want to execute
- extra_stop_points: A collection of addresses at which execution should halt

**__init__**(*project*)

**Parameters**
**project** (Project)

### 10.15.13 angr.engines.vex

**class** angr.engines.vex.**ClaripyDataMixin**

Bases: *VEXMixin*

This mixin provides methods that makes the vex engine process guest code using claripy ASTs as the data domain.

**class** angr.engines.vex.**HeavyResilienceMixin**

Bases: *VEXResilienceMixin*, *ClaripyDataMixin*

**class** angr.engines.vex.**HeavyVEXMixin**

Bases: *SuccessorsEngine*, *ClaripyDataMixin*, *SimStateStorageMixin*, *VEXMixin*, *VEXLifter*

Execution engine based on VEX, Valgrind's IR.

Responds to the following parameters to the step stack:

- irsb: The PyVEX IRSB object to use for execution. If not provided one will be lifted.
- skip_stmts: The number of statements to skip in processing
- last_stmt: Do not execute any statements after this statement
- whitelist: Only execute statements in this set
- thumb: Whether the block should be force to be lifted in ARM's THUMB mode.
- **extra_stop_points:**
  An extra set of points at which to break basic blocks
- opt_level: The VEX optimization level to use.
- insn_bytes: A string of bytes to use for the block instead of the project.
- size: The maximum size of the block, in bytes.
- num_inst: The maximum number of instructions.
- traceflags: traceflags to be passed to VEX. (default: 0)

**class** angr.engines.vex.**SimInspectMixin**

Bases: *VEXMixin*

**handle_vex_block**(*irsb*)

**class** angr.engines.vex.**SuperFastpathMixin**

Bases: *VEXSlicingMixin*

This mixin implements the superfastpath execution mode, which skips all but the last four instructions.

**handle_vex_block**(*irsb*)

**class** angr.engines.vex.**TrackActionsMixin**

Bases: *HeavyVEXMixin*

**__init__**(**args*, ***kwargs*)

**handle_vex_block**(*irsb*)

class angr.engines.vex.**VEXLifter**

Bases: *SimEngine*

Implements the VEX lifter engine mixin.

**__init__**(*project*, *use_cache=None*, *cache_size=5000*, *default_opt_level=1*, *selfmodifying_code=None*, *single_step=False*, *default_strict_block_end=False*, ***kwargs*)

**clear_cache**()

**lift_vex**(*addr=None*, *state=None*, *clemory=None*, *insn_bytes=None*, *offset=None*, *arch=None*, *size=None*, *num_inst=None*, *traceflags=0*, *thumb=False*, *extra_stop_points=None*, *opt_level=None*, *strict_block_end=None*, *skip_stmts=False*, *collect_data_refs=False*, *cross_insn_opt=None*, *load_from_ro_regions=False*, *const_prop=False*)

Lift an IRSB.

There are many possible valid sets of parameters. You at the very least must pass some source of data, some source of an architecture, and some source of an address.

Sources of data in order of priority: insn_bytes, clemory, state

Sources of an address, in order of priority: addr, state

Sources of an architecture, in order of priority: arch, clemory, state

**Parameters**

- **state** – A state to use as a data source.
- **clemory** (Clemory | ClemoryReadOnlyView | None) – A cle.memory.Clemory object to use as a data source.
- **addr** – The address at which to start the block.
- **thumb** – Whether the block should be lifted in ARM's THUMB mode.
- **opt_level** – The VEX optimization level to use. The final IR optimization level is determined by (ordered by priority): - Argument opt_level - opt_level is set to 1 if OPTIMIZE_IR exists in state options - self._default_opt_level
- **insn_bytes** (bytes | None) – A string of bytes to use as a data source.
- **offset** – If using insn_bytes, the number of bytes in it to skip over.
- **size** – The maximum size of the block, in bytes.
- **num_inst** – The maximum number of instructions.
- **traceflags** – traceflags to be passed to VEX. (default: 0)
- **strict_block_end** – Whether to force blocks to end at all conditional branches (default: false)

**Return type**
IRSB

class angr.engines.vex.**VEXMixin**

Bases: *SimEngine*

**__init__**(*project*, ***kwargs*)

**handle_vex_block**(*irsb*)

**Parameters**
**irsb** (*IRSB*)

**class** angr.engines.vex.**VEXResilienceMixin**

Bases: *VEXMixin*

**class** angr.engines.vex.**VEXSlicingMixin**

Bases: *VEXMixin*

**__init__**(**args*, ***kwargs*)

**process**(*state*, *block=None*, *skip_stmts=0*, *last_stmt=None*, *whitelist=None*, ***kwargs*)

**handle_vex_block**(*irsb*)

**Parameters**
**platform** (Platform)

angr.engines.vex.claripy.ccall.**pc_actions_UMUL**(*state*, *nbits*, *cc_dep1*, *cc_dep2*, *cc_ndep*, *platform*)

**Parameters**
**platform** (Platform)

angr.engines.vex.claripy.ccall.**pc_actions_UMULQ**(**args*, ***kwargs*)

angr.engines.vex.claripy.ccall.**pc_actions_SMUL**(*state*, *nbits*, *cc_dep1*, *cc_dep2*, *cc_ndep*, *platform*)

**Parameters**
**platform** (Platform)

angr.engines.vex.claripy.ccall.**pc_actions_SMULQ**(**args*, ***kwargs*)

angr.engines.vex.claripy.ccall.**pc_calculate_rdata_all_WRK**(*state*, *cc_op*, *cc_dep1_formal*, *cc_dep2_formal*, *cc_ndep_formal*, *platform*)

**Parameters**
**platform** (Platform)

angr.engines.vex.claripy.ccall.**pc_calculate_rdata_all**(*state*, *cc_op*, *cc_dep1*, *cc_dep2*, *cc_ndep*, *platform*)

**Parameters**
**platform** (Platform)

angr.engines.vex.claripy.ccall.**pc_calculate_condition**(*state*, *cond*, *cc_op*, *cc_dep1*, *cc_dep2*, *cc_ndep*, *platform*)

**Parameters**
**platform** (Platform)

angr.engines.vex.claripy.ccall.**pc_actions_op_SUB**(*arg_l*, *arg_r*, *cc_ndep*)

angr.engines.vex.claripy.ccall.**pc_actions_op_DEC**(*arg_l*, *arg_r*, *cc_ndep*)

angr.engines.vex.claripy.ccall.**pc_actions_op_INC**(*arg_l*, *arg_r*, *cc_ndep*)

angr.engines.vex.claripy.ccall.**pc_actions_op_SHR**(*arg_l*, *arg_r*, *cc_ndep*)

angr.engines.vex.claripy.ccall.**pc_actions_op_SHL**(*arg_l*, *arg_r*, *cc_ndep*)

angr.engines.vex.claripy.ccall.**pc_actions_op_ADD**(*arg_l*, *arg_r*, *cc_ndep*)

angr.engines.vex.claripy.ccall.**pc_actions_op_LOGIC**(*arg_l*, *arg_r*, *cc_ndep*)

angr.engines.vex.claripy.ccall.**pc_actions_cond_CondZ**(*state*, *cc_expr*)

angr.engines.vex.claripy.ccall.**pc_actions_cond_CondNZ**(*state*, *cc_expr*)

angr.engines.vex.claripy.ccall.**pc_actions_cond_CondS**(*state*, *cc_expr*)

angr.engines.vex.claripy.ccall.**pc_actions_cond_CondB**(*state*, *cc_expr*)

angr.engines.vex.claripy.ccall.**pc_actions_cond_CondBE**(*state*, *cc_expr*)

angr.engines.vex.claripy.ccall.**pc_actions_cond_CondNBE**(*state*, *cc_expr*)

angr.engines.vex.claripy.ccall.**pc_actions_cond_CondL**(*state*, *cc_expr*)

angr.engines.vex.claripy.ccall.**pc_actions_cond_CondLE**(*state*, *cc_expr*)

angr.engines.vex.claripy.ccall.**pc_actions_cond_CondNLE**(*state*, *cc_expr*)

angr.engines.vex.claripy.ccall.**pc_actions_SUB_CondZ**(*state*, *arg_l*, *arg_r*, *cc_ndep*)

angr.engines.vex.claripy.ccall.**pc_actions_SUB_CondNZ**(*state*, *arg_l*, *arg_r*, *cc_ndep*)

angr.engines.vex.claripy.ccall.**pc_actions_SUB_CondB**(*state*, *arg_l*, *arg_r*, *cc_ndep*)

angr.engines.vex.claripy.ccall.**pc_actions_SUB_CondBE**(*state*, *arg_l*, *arg_r*, *cc_ndep*)

angr.engines.vex.claripy.ccall.**pc_actions_SUB_CondNBE**(*state*, *arg_l*, *arg_r*, *cc_ndep*)

angr.engines.vex.claripy.ccall.**pc_actions_SUB_CondL**(*state*, *arg_l*, *arg_r*, *cc_ndep*)

angr.engines.vex.claripy.ccall.**pc_actions_SUB_CondLE**(*state*, *arg_l*, *arg_r*, *cc_ndep*)

angr.engines.vex.claripy.ccall.**pc_actions_SUB_CondNLE**(*state*, *arg_l*, *arg_r*, *cc_ndep*)

angr.engines.vex.claripy.ccall.**pc_calculate_condition_simple**(*state*, *cond*, *cc_op*, *cc_dep1*, *cc_dep2*, *cc_ndep*, *platform*)

A simplified version of pc_calculate_condition(). Please refer to the documentation of Simplified CCalls above.

Limitation: symbolic flags are not supported for now.

**Parameters**
**platform** (Platform)

angr.engines.vex.claripy.ccall.**pc_calculate_rdata_c**(*state*, *cc_op*, *cc_dep1*, *cc_dep2*, *cc_ndep*, *platform*)

**Parameters**
**platform** (Platform)

angr.engines.vex.claripy.ccall.**generic_rotate_with_carry**(*state*, *left*, *arg*, *rot_amt*, *carry_bit_in*, *sz*)

angr.engines.vex.claripy.ccall.**amd64g_check_ldmxcsr**(*state*, *mxcsr*)

### angr.engines.vex.claripy.datalayer

angr.engines.vex.claripy.datalayer.**value**(*ty*, *val*, *size=None*)

**Parameters**

- **ty** (*str*)
- **val** (*float*)
- **size** (*int | None*)

angr.engines.vex.claripy.datalayer.**value_bv**(*ty*, *val*, *size=None*)

Like value(), but floating-point constants are returned as bitvectors holding their IEEE bit pattern.

**Return type**
BV

**Parameters**

- **ty** (*str*)
- **val** (*float*)
- **size** (*int | None*)

angr.engines.vex.claripy.datalayer.**symbol**(*ty*, *name*)

**class** angr.engines.vex.claripy.datalayer.**ClaripyDataMixin**

Bases: *VEXMixin*

This mixin provides methods that makes the vex engine process guest code using claripy ASTs as the data domain.

### angr.engines.vex.claripy.irop

This module contains symbolic implementations of VEX operations.

angr.engines.vex.claripy.irop.**op_attrs**(*p*)

angr.engines.vex.claripy.irop.**make_operations**()

angr.engines.vex.claripy.irop.**translate_rm**(*rm_num*)

angr.engines.vex.claripy.irop.**supports_vector**(*f*)

**class** angr.engines.vex.claripy.irop.**SimIROp**

Bases: object

A symbolic version of a Vex IR operation.

**__init__**(*name*, ***attrs*)

**name**

**op_attrs**

**calculate**(**args*)

**extend_size**(*o*)

**property is_signed**

**NO_RM = {'Abs', 'Neg'}**

**vector_args**(*args*)

Yields each of the individual lane pairs from the arguments, in order from most significan to least significant

**generic_minmax**(*args*, *cmp_op*)

**generic_compare**(*args*, *comparison*)

**generic_shift_thing**(*args*, *op*)

**static pow**(*rm*, *arg*, *n*)

angr.engines.vex.claripy.irop.**vexop_to_simop**(*op*, *extended=True*, *fp=True*)

### angr.engines.vex.heavy

**class** angr.engines.vex.heavy.**HeavyResilienceMixin**

Bases: *VEXResilienceMixin*, *ClaripyDataMixin*

**class** angr.engines.vex.heavy.**HeavyVEXMixin**

Bases: *SuccessorsEngine*, *ClaripyDataMixin*, *SimStateStorageMixin*, *VEXMixin*, *VEXLifter*

Execution engine based on VEX, Valgrind's IR.

Responds to the following parameters to the step stack:

- irsb: The PyVEX IRSB object to use for execution. If not provided one will be lifted.
- skip_stmts: The number of statements to skip in processing
- last_stmt: Do not execute any statements after this statement
- whitelist: Only execute statements in this set
- thumb: Whether the block should be force to be lifted in ARM's THUMB mode.
- **extra_stop_points:**
  An extra set of points at which to break basic blocks
- opt_level: The VEX optimization level to use.
- insn_bytes: A string of bytes to use for the block instead of the project.
- size: The maximum size of the block, in bytes.
- num_inst: The maximum number of instructions.
- traceflags: traceflags to be passed to VEX. (default: 0)

**class** angr.engines.vex.heavy.**SimInspectMixin**

Bases: *VEXMixin*

**handle_vex_block**(*irsb*)

**class** angr.engines.vex.heavy.**SuperFastpathMixin**

Bases: *VEXSlicingMixin*

This mixin implements the superfastpath execution mode, which skips all but the last four instructions.

**handle_vex_block**(*irsb*)

**class** angr.engines.vex.heavy.**TrackActionsMixin**

Bases: *HeavyVEXMixin*

**__init__**(**args*, ***kwargs*)

**handle_vex_block**(*irsb*)

### Submodules

*actions*
*concretizers*
*dirty*
*heavy*

### angr.engines.vex.heavy.heavy

**exception** angr.engines.vex.heavy.heavy.**VEXEarlyExit**

Bases: Exception

**class** angr.engines.vex.heavy.heavy.**SimStateStorageMixin**

Bases: *VEXMixin*

**class** angr.engines.vex.heavy.heavy.**HeavyVEXMixin**

Bases: *SuccessorsEngine*, *ClaripyDataMixin*, *SimStateStorageMixin*, *VEXMixin*, *VEXLifter*

Execution engine based on VEX, Valgrind's IR.

Responds to the following parameters to the step stack:

- irsb: The PyVEX IRSB object to use for execution. If not provided one will be lifted.
- skip_stmts: The number of statements to skip in processing
- last_stmt: Do not execute any statements after this statement
- whitelist: Only execute statements in this set
- thumb: Whether the block should be force to be lifted in ARM's THUMB mode.
- **extra_stop_points:**
  An extra set of points at which to break basic blocks
- opt_level: The VEX optimization level to use.
- insn_bytes: A string of bytes to use for the block instead of the project.
- size: The maximum size of the block, in bytes.
- num_inst: The maximum number of instructions.
- traceflags: traceflags to be passed to VEX. (default: 0)

### angr.engines.vex.heavy.inspect

**class** angr.engines.vex.heavy.inspect.**SimInspectMixin**

Bases: *VEXMixin*

**handle_vex_block**(*irsb*)

### angr.engines.vex.heavy.resilience

**class** angr.engines.vex.heavy.resilience.**HeavyResilienceMixin**

Bases: *VEXResilienceMixin*, *ClaripyDataMixin*

### angr.engines.vex.heavy.super_fastpath

**class** angr.engines.vex.heavy.super_fastpath.**SuperFastpathMixin**

Bases: *VEXSlicingMixin*

This mixin implements the superfastpath execution mode, which skips all but the last four instructions.

**handle_vex_block**(*irsb*)

### angr.engines.vex.lifter

**class** angr.engines.vex.lifter.**VEXLifter**

Bases: *SimEngine*

Implements the VEX lifter engine mixin.

**__init__**(*project*, *use_cache=None*, *cache_size=5000*, *default_opt_level=1*, *selfmodifying_code=None*, *single_step=False*, *default_strict_block_end=False*, ***kwargs*)

**clear_cache**()

**lift_vex**(*addr=None*, *state=None*, *clemory=None*, *insn_bytes=None*, *offset=None*, *arch=None*, *size=None*, *num_inst=None*, *traceflags=0*, *thumb=False*, *extra_stop_points=None*, *opt_level=None*, *strict_block_end=None*, *skip_stmts=False*, *collect_data_refs=False*, *cross_insn_opt=None*, *load_from_ro_regions=False*, *const_prop=False*)

Lift an IRSB.

There are many possible valid sets of parameters. You at the very least must pass some source of data, some source of an architecture, and some source of an address.

Sources of data in order of priority: insn_bytes, clemory, state

Sources of an address, in order of priority: addr, state

Sources of an architecture, in order of priority: arch, clemory, state

**Parameters**

- **state** – A state to use as a data source.
- **clemory** (Clemory | ClemoryReadOnlyView | None) – A cle.memory.Clemory object to use as a data source.
- **addr** – The address at which to start the block.
- **thumb** – Whether the block should be lifted in ARM's THUMB mode.
- **opt_level** – The VEX optimization level to use. The final IR optimization level is determined by (ordered by priority): - Argument opt_level - opt_level is set to 1 if OPTIMIZE_IR exists in state options - self._default_opt_level
- **insn_bytes** (bytes | None) – A string of bytes to use as a data source.
- **offset** – If using insn_bytes, the number of bytes in it to skip over.
- **size** – The maximum size of the block, in bytes.
- **num_inst** – The maximum number of instructions.
- **traceflags** – traceflags to be passed to VEX. (default: 0)
- **strict_block_end** – Whether to force blocks to end at all conditional branches (default: false)

**Return type**
IRSB

### angr.engines.vex.light

Bases: *AngrDecompilationError*

Raised when a function exceeds one of the decompiler's complexity limits. The decompiler gives up before starting the expensive work instead of running for an unbounded amount of time.

**Variables**

- **limit_name** – Name of the decompilation option that sets the limit, e.g. "max_function_blocks".
- **limit** – The configured limit.
- **actual** – The measured size that exceeded the limit.
- **func_addr** – Address of the offending function, if known.
- **unit** – What `actual` counts, e.g. "basic blocks".

**exception** angr.errors.**UnsupportedNodeTypeError**

Bases: *AngrError*, NotImplementedError

**exception** angr.errors.**AngrAIError**

Bases: *AngrError*

## 10.18 angr.exploration_techniques

**class** angr.exploration_techniques.**DFS**

Bases: *ExplorationTechnique*

Depth-first search.

Will only keep one path active at a time, any others will be stashed in the 'deferred' stash. When we run out of active paths to step, we take the longest one from deferred and continue.

**__init__**(*deferred_stash='deferred'*)

**class** angr.exploration_techniques.**Bucketizer**

Bases: *ExplorationTechnique*

Loop bucketization: Pick log(n) paths out of n possible paths, and stash (or drop) everything else.

**class** angr.exploration_techniques.**CallFunctionGoal**

Bases: *BaseGoal*

A goal that prioritizes states reaching certain function, and optionally with specific arguments. Note that constraints on arguments (and on function address as well) have to be identifiable on an accurate CFG. For example, you may have a CallFunctionGoal saying "call printf with the first argument being 'Hello, world'", and CFGEmulated must be able to figure our the first argument to printf is in fact "Hello, world", not some symbolic strings that will be constrained to "Hello, world" during symbolic execution (or simulation, however you put it).

**REQUIRE_CFG_STATES = True**

**__init__**(*function*, *arguments*)

**check**(*cfg*, *state*, *peek_blocks*)

Check if the specified function will be reached with certain arguments.

**Parameters**

- **cfg**
- **state**
- **peek_blocks**

**Returns**

**check_state**(*state*)

Check if the specific function is reached with certain arguments

**Parameters**
**state** (*angr.SimState*) – The state to check

**Returns**
True if the function is reached with certain arguments, False otherwise.

**Return type**
bool

**class** angr.exploration_techniques.**DirectedSearch**

Bases: *ExplorationTechnique*

Best-first search toward a target address, ranked by distance in a CFG.

After every step, the states in the stepped stash and in `deferred_stash` are ranked together by their distance to `target_addr`, and the `beam_width` closest stay in the stepped stash. The rest wait in `deferred_stash`, so a deferred state comes back as soon as it is among the closest. Ties keep the earlier-deferred state first. The technique keeps `deferred_stash` sorted by distance.

The distance of a state is the fewest CFG edges from the block holding its address to the block holding the target. It is a heuristic: every block counts as one hop, and it ignores calling context, so from inside a function the shortest return to *any* caller counts. States whose address is not in the CFG, or that cannot reach the target, rank last.

A state that loops close to the target stays ahead of farther ones indefinitely; pair this technique with `LoopSeer` or `LengthLimiter` when that can happen. Use one instance per stepped stash: states in `deferred_stash` can move into whichever stash is stepped, and successors sent elsewhere with `target_stash` are not ranked.

**__init__**(*cfg*, *target_addr*, *beam_width=1*, *deferred_stash='directed_deferred'*)

**Parameters**

- **cfg** – A CFG analysis (e.g. `project.analyses.CFGFast()`) or its `CFGModel`.
- **target_addr** (`int`) – The address to steer toward. It need not start a block.
- **beam_width** (`int`) – How many of the closest states to keep after each step (at least 1).
- **deferred_stash** (`str`) – The stash for states that are not among the closest.

**Raises**
`ValueError` – If `beam_width` is below 1, or no CFG node contains `target_addr`.

**distance**(*addr*)

The CFG distance from `addr` to the target, or `inf` when `addr` is not in the CFG or cannot reach it.

**Return type**
`float`

**Parameters**
**addr** (*int*)

**class** angr.exploration_techniques.**Director**

Bases: *ExplorationTechnique*

An exploration technique for directed symbolic execution.

A control flow graph (using CFGEmulated) is built and refined during symbolic execution. Each time the execution reaches a block that is outside of the CFG, the CFG recovery will be triggered with that state, with a maximum recovery depth (100 by default). If we see a basic block during state stepping that is not yet in the control flow graph, we go back to control flow graph recovery and "peek" more blocks forward.

When stepping a simulation manager, all states are categorized into three different categories:

- Might reach the destination within the peek depth. Those states are prioritized.
- Will not reach the destination within the peek depth. Those states are de-prioritized. However, there is a little chance for those states to be explored as well in order to prevent over-fitting.

**__init__**(*peek_blocks=100*, *peek_functions=5*, *goals=None*, *cfg_keep_states=False*, *goal_satisfied_callback=None*, *num_fallback_states=5*)

Constructor.

**step**(*simgr*, *stash='active'*, ***kwargs*)

**Parameters**

- **simgr**
- **stash**
- **kwargs**

**Returns**

**add_goal**(*goal*)

Add a goal.

**Parameters**
**goal** (BaseGoal) – The goal to add.

**Returns**
None

**class** angr.exploration_techniques.**DrillerCore**

Bases: *ExplorationTechnique*

An exploration technique that symbolically follows an input looking for new state transitions.

It has to be used with Tracer exploration technique. Results are put in 'diverted' stash.

**__init__**(*trace*, *fuzz_bitmap=None*)

:param trace : The basic block trace. :type fuzz_bitmap: :param fuzz_bitmap: AFL's bitmap of state transitions. Defaults to saying every transition is worth satisfying.

**class** angr.exploration_techniques.**ExecuteAddressGoal**

Bases: *BaseGoal*

A goal that prioritizes states reaching (or are likely to reach) certain address in some specific steps.

**__init__**(*addr*)

**check**(*cfg*, *state*, *peek_blocks*)

Check if the specified address will be executed

**Parameters**

- **cfg**
- **state**
- **peek_blocks** (*int*)

**Returns**

**Return type**
bool

**check_state**(*state*)

Check if the current address is the target address.

**Parameters**
**state** (*angr.SimState*) – The state to check.

**Returns**
True if the current address is the target address, False otherwise.

**Return type**
bool

**class** angr.exploration_techniques.**ExplorationTechnique**

Bases: object

An ExplorationTechnique is a set of hooks for a simulation manager that assists in the implementation of new techniques in symbolic exploration.

Any number of these methods may be overridden by a subclass. To use an exploration technique, call `simgr.use_technique` with an *instance* of the technique.

**__init__**()

**setup**(*simgr*)

Perform any initialization on this manager you might need to do.

**Parameters**
**simgr** (*angr.SimulationManager*) – The simulation manager to which you have just been added

**step**(*simgr*, *stash='active'*, ***kwargs*)

Hook the process of stepping a stash forward. Should call `simgr.step(stash, **kwargs)` in order to do the actual processing.

**Parameters**

- **simgr** (*angr.SimulationManager*)
- **stash** (*str*)

**filter**(*simgr*, *state*, ***kwargs*)

Perform filtering on which stash a state should be inserted into.

If the state should be filtered, return the name of the stash to move the state to. If you want to modify the state before filtering it, return a tuple of the stash to move the state to and the modified state. To defer to the original categorization procedure, return the result of `simgr.filter(state, **kwargs)`

If the user provided a `filter_func` in their step or run command, it will appear here.

**Parameters**

- **simgr** (*angr.SimulationManager*)
- **state** (*angr.SimState*)

**selector**(*simgr*, *state*, ***kwargs*)

Determine if a state should participate in the current round of stepping. Return True if the state should be stepped, and False if the state should not be stepped. To defer to the original selection procedure, return the result of `simgr.selector(state, **kwargs)`.

If the user provided a `selector_func` in their step or run command, it will appear here.

**Parameters**

- **simgr** (*angr.SimulationManager*)
- **state** (*angr.SimState*)

**step_state**(*simgr*, *state*, ***kwargs*)

Determine the categorization of state successors into stashes. The result should be a dict mapping stash names to the list of successor states that fall into that stash, or None as a stash name to use the original stash name.

If you would like to directly work with a *SimSuccessors* object, you can obtain it with `simgr.successors(state, **kwargs)`. This is not recommended, as it denies other hooks the opportunity to look at the successors. Therefore, the usual technique is to call `simgr.step_state(state, **kwargs)` and then mutate the returned dict before returning it yourself.

..note:: This takes precedence over the *filter* hook - *filter* is only applied to states returned from here in the None stash.

**Parameters**

- **simgr** (*angr.SimulationManager*)
- **state** (*angr.SimState*)

**successors**(*simgr*, *state*, ***kwargs*)

Perform the process of stepping a state forward, returning a SimSuccessors object.

To defer to the original succession procedure, return the result of `simgr.successors(state, **kwargs)`. Be careful about not calling this method (e.g. calling `project.factory.successors` manually) as it denies other hooks the opportunity to instrument the step. Instead, you can mutate the kwargs for the step before calling the original, and mutate the result before returning it yourself.

If the user provided a `successor_func` in their step or run command, it will appear here.

**Parameters**

- **simgr** (*angr.SimulationManager*)
- **state** (*angr.SimState*)

**complete**(*simgr*)

Return whether or not this manager has reached a "completed" state, i.e. `SimulationManager.run()` should halt.

This is the one hook which is *not* subject to the nesting rules of hooks. You should *not* call `simgr.complete`, you should make your own decision and return True or False. Each of the techniques' completion checkers will be called and the final result will be compted with `simgr.completion_mode`.

**Parameters**

**simgr** (*angr.SimulationManager*)

class angr.exploration_techniques.**Explorer**

Bases: *ExplorationTechnique*

Search for up to "num_find" paths that satisfy condition "find", avoiding condition "avoid". Stashes found paths into "find_stash' and avoided paths into "avoid_stash".

The "find" and "avoid" parameters may be any of:

- An address to find
- A set or list of addresses to find
- A function that takes a path and returns whether or not it matches.

If an angr CFG is passed in as the "cfg" parameter and "find" is either a number or a list or a set, then any paths which cannot possibly reach a success state without going through a failure state will be preemptively avoided.

If either the "find" or "avoid" parameter is a function returning a boolean, and a path triggers both conditions, it will be added to the find stash, unless "avoid_priority" is set to True.

**__init__**(*find=None*, *avoid=None*, *find_stash='found'*, *avoid_stash='avoid'*, *cfg=None*, *num_find=1*, *avoid_priority=False*)

class angr.exploration_techniques.**LengthLimiter**

Bases: *ExplorationTechnique*

Length limiter on paths.

**__init__**(*max_length*, *drop=False*)

class angr.exploration_techniques.**LocalLoopSeer**

Bases: *ExplorationTechnique*

LocalLoopSeer monitors exploration and maintains all loop-related data without relying on a control flow graph.

**__init__**(*bound=None*, *bound_reached=None*, *discard_stash='spinning'*)

**Parameters**

- **bound** – Limit the number of iterations a loop may be executed.
- **bound_reached** – If provided, should be a function that takes the LoopSeer and the succ_state. Will be called when loop execution reach the given bound. Default to moving states that exceed the loop limit to a discard stash.
- **discard_stash** – Name of the stash containing states exceeding the loop limit.

class angr.exploration_techniques.**LoopSeer**

Bases: *ExplorationTechnique*

This exploration technique monitors exploration and maintains all loop-related data (well, currently it is just the loop trip counts, but feel free to add something else).

**__init__**(*cfg=None*, *functions=None*, *loops=None*, *use_header=False*, *bound=None*, *bound_reached=None*, *discard_stash='spinning'*, *limit_concrete_loops=True*)

**Parameters**

- **cfg** – Normalized CFG is required.
- **functions** – Function(s) containing the loop(s) to be analyzed.
- **loops** – Specific group of Loop(s) to be analyzed, if this is None we run the LoopFinder analysis.

- **use_header** – Whether to use header based trip counter to compare with the bound limit.
- **bound** – Limit the number of iterations a loop may be executed.
- **bound_reached** – If provided, should be a function that takes the LoopSeer and the succ_state. Will be called when loop execution reach the given bound. Default to moving states that exceed the loop limit to a discard stash.
- **discard_stash** – Name of the stash containing states exceeding the loop limit.
- **limit_concrete_loops** – If False, do not limit a loop back-edge if it is the only successor (Defaults to True to maintain the original behavior)

class angr.exploration_techniques.**ManualMergepoint**

Bases: *ExplorationTechnique*

**__init__**(*address*, *wait_counter=10*, *prune=True*)

**mark_nofilter**(*simgr*, *stash*)

**mark_okfilter**(*simgr*, *stash*)

class angr.exploration_techniques.**MemoryWatcher**

Bases: *ExplorationTechnique*

Memory Watcher

**Parameters**

- **min_memory** (*int*, optional) – Minimum amount of free memory in MB before stopping execution (default: 95% memory use)
- **memory_stash** (*str*, optional) – What to call the low memory stash (default: 'lowmem')

At each step, keep an eye on how much memory is left on the system. Stash off states to effectively stop execution if we're below a given threshold.

**__init__**(*min_memory=512*, *memory_stash='lowmem'*)

class angr.exploration_techniques.**Oppologist**

Bases: *ExplorationTechnique*

The Oppologist is an exploration technique that forces uncooperative code through qemu.

**__init__**()

class angr.exploration_techniques.**Slicecutor**

Bases: *ExplorationTechnique*

The Slicecutor is an exploration that executes provided code slices.

**__init__**(*annotated_cfg*, *force_taking_exit=False*, *force_sat=False*)

All parameters except *annotated_cfg* are optional.

**Parameters**

- **annotated_cfg** – The AnnotatedCFG that provides the code slice.
- **force_taking_exit** – Set to True if you want to create a successor based on our slice in case of unconstrained successors.
- **force_sat** (bool) – If a branch specified by the slice is unsatisfiable, set this option to True if you want to force it to be satisfiable and be taken anyway.

class angr.exploration_techniques.**Spiller**

Bases: *ExplorationTechnique*

Automatically spill states out. It can spill out states to a different stash, spill them out to ANA, or first do the former and then (after enough states) the latter.

**__init__**(*src_stash='active'*, *min=5*, *max=10*, *staging_stash='spill_stage'*, *staging_min=10*, *staging_max=20*, *pickle_callback=None*, *unpickle_callback=None*, *post_pickle_callback=None*, *priority_key=None*, *vault=None*, *states_collection=None*)

Initializes the spiller.

**Parameters**

- **max** – the number of states that are *not* spilled
- **src_stash** – the stash from which to spill states (default: active)
- **staging_stash** – the stash *to* which to spill states (default: "spill_stage")
- **staging_max** – the number of states that can be in the staging stash before things get spilled to ANA (default: None. If staging_stash is set, then this means unlimited, and ANA will not be used).
- **priority_key** – a function that takes a state and returns its numerical priority (MAX_INT is lowest priority). By default, self.state_priority will be used, which prioritizes by object ID.
- **vault** – an angr.Vault object to handle storing and loading of states. If not provided, an angr.vaults.VaultShelf will be created with a temporary file.

**static state_priority**(*state*)

class angr.exploration_techniques.**StochasticSearch**

Bases: *ExplorationTechnique*

Stochastic Search.

Will only keep one path active at a time, any others will be discarded. Before each pass through, weights are randomly assigned to each basic block. These weights form a probability distribution for determining which state remains after splits. When we run out of active paths to step, we start again from the start state.

**__init__**(*start_state*, *restart_prob=0.0001*)

**Parameters**

- **start_state** – The initial state from which exploration stems.
- **restart_prob** – The probability of randomly restarting the search (default 0.0001).

class angr.exploration_techniques.**StubStasher**

Bases: *ExplorationTechnique*

Stash states that reach a stub SimProcedure.

**static post_filter**(*state*)

class angr.exploration_techniques.**Suggestions**

Bases: *ExplorationTechnique*

An exploration technique which analyzes failure cases and logs suggestions for how to mitigate them in future analyses.

**__init__**()

**static report**(*state*, *event*)

**class** angr.exploration_techniques.**TechniqueBuilder**

Bases: *ExplorationTechnique*

This meta technique could be used to hook a couple of simulation manager methods without actually creating a new exploration technique, for example:

class SomeComplexAnalysis(Analysis):

**def do_something():**
simgr = self.project.factory.simulation_manager() simgr.use_tech(ProxyTechnique(step_state=self._step_state)) simgr.run()

**def _step_state(self, state):**
# Do stuff! pass

In the above example, the _step_state method can access all the necessary stuff, hidden in the analysis instance, without passing that instance to a one-shot-styled exploration technique.

**__init__**(*setup=None*, *step_state=None*, *step=None*, *successors=None*, *filter=None*, *selector=None*, *complete=None*)

**class** angr.exploration_techniques.**Threading**

Bases: *ExplorationTechnique*

Enable multithreading.

This is only useful in paths where a lot of time is taken inside z3, doing constraint solving. This is because of python's GIL, which says that only one thread at a time may be executing python code.

**__init__**(*threads=8*, *local_stash='thread_local'*)

**inner_step**(*state*, *simgr*, ***kwargs*)

**class** angr.exploration_techniques.**Timeout**

Bases: *ExplorationTechnique*

Timeout exploration technique that stops an active exploration if the run time exceeds a predefined timeout

**__init__**(*timeout=None*)

**class** angr.exploration_techniques.**Tracer**

Bases: *ExplorationTechnique*

An exploration technique that follows an angr path with a concrete input. The tracing result is the state at the last address of the trace, which can be found in the 'traced' stash.

If the given concrete input makes the program crash, you should provide crash_addr, and the crashing state will be found in the 'crashed' stash.

**Parameters**

- **trace** (list[int]) – The basic block trace.
- **resiliency** – Should we continue to step forward even if qemu and angr disagree?
- **keep_predecessors** – Number of states before the final state we should log.
- **crash_addr** – If the trace resulted in a crash, provide the crashing instruction pointer here, and the 'crashed' stash will be populated with the crashing state.
- **syscall_data** – Data related to various syscalls recorded by tracer for replaying

- **copy_states** – Whether COPY_STATES should be enabled for the tracing state. It is off by default because most tracing workloads benefit greatly from not performing copying. You want to enable it if you want to see the missed states. It will be re-added for the last 2% of the trace in order to set the predecessors list correctly. If you turn this on you may want to enable the LAZY_SOLVES option.
- **mode** – Tracing mode.
- **aslr** – Whether there are aslr slides. if not, tracer uses trace address as state address.
- **follow_unsat** – Whether unsatisfiable states should be treated as potential successors or not.

**Variables**
**predecessors** (list[*SimState*]) – A list of states in the history before the final state.

**__init__**(*trace*, *resiliency=False*, *keep_predecessors=1*, *crash_addr=None*, *syscall_data=None*, *copy_states=False*, *fast_forward_to_entry=True*, *mode='strict'*, *aslr=True*, *follow_unsat=False*)

**Parameters**
**trace** (*list[int]*)

**set_fd_data**(*fd_data*)

Set concrete bytes of various fds read by the program

**Parameters**
**fd_data** (*dict[int, bytes]*)

**classmethod crash_windup**(*state*, *crash_addr*)

**class** angr.exploration_techniques.**UniqueSearch**

Bases: *ExplorationTechnique*

Unique Search.

Will only keep one path active at a time, any others will be deferred. The state that is explored depends on how unique it is relative to the other deferred states. A path's uniqueness is determined by its average similarity between the other (deferred) paths. Similarity is calculated based on the supplied *similarity_func*, which by default is: The (L2) distance between the counts of the state addresses in the history of the path.

**__init__**(*similarity_func=None*, *deferred_stash='deferred'*)

**Parameters**

- **similarity_func** – How to calculate similarity between two states.
- **deferred_stash** – Where to store the deferred states.

**static similarity**(*state_a*, *state_b*)

The (L2) distance between the counts of the state addresses in the history of the path. :type state_a: :param state_a: The first state to compare :type state_b: :param state_b: The second state to compare

**static sequence_matcher_similarity**(*state_a*, *state_b*)

The *difflib.SequenceMatcher* ratio between the state addresses in the history of the path. :type state_a: :param state_a: The first state to compare :type state_b: :param state_b: The second state to compare

**class** angr.exploration_techniques.**Veritesting**

Bases: *ExplorationTechnique*

Enable veritesting. This technique, described in a paper[1] from CMU, attempts to address the problem of state explosions in loops by performing smart merging.

[1] https://users.ece.cmu.edu/~aavgerin/papers/veritesting-icse-2014.pdf

## 10.18.1 angr.exploration_techniques.base

**class** angr.exploration_techniques.base.**ExplorationTechnique**

Bases: object

An ExplorationTechnique is a set of hooks for a simulation manager that assists in the implementation of new techniques in symbolic exploration.

Any number of these methods may be overridden by a subclass. To use an exploration technique, call `simgr.use_technique` with an *instance* of the technique.

**__init__**()

**setup**(*simgr*)

Perform any initialization on this manager you might need to do.

**Parameters**
**simgr** (*angr.SimulationManager*) – The simulation manager to which you have just been added

**step**(*simgr*, *stash='active'*, ***kwargs*)

Hook the process of stepping a stash forward. Should call `simgr.step(stash, **kwargs)` in order to do the actual processing.

**Parameters**

- **simgr** (*angr.SimulationManager*)
- **stash** (*str*)

**filter**(*simgr*, *state*, ***kwargs*)

Perform filtering on which stash a state should be inserted into.

If the state should be filtered, return the name of the stash to move the state to. If you want to modify the state before filtering it, return a tuple of the stash to move the state to and the modified state. To defer to the original categorization procedure, return the result of `simgr.filter(state, **kwargs)`

If the user provided a `filter_func` in their step or run command, it will appear here.

**Parameters**

- **simgr** (*angr.SimulationManager*)
- **state** (*angr.SimState*)

**selector**(*simgr*, *state*, ***kwargs*)

Determine if a state should participate in the current round of stepping. Return True if the state should be stepped, and False if the state should not be stepped. To defer to the original selection procedure, return the result of `simgr.selector(state, **kwargs)`.

If the user provided a `selector_func` in their step or run command, it will appear here.

**Parameters**

- **simgr** (*angr.SimulationManager*)
- **state** (*angr.SimState*)

**step_state**(*simgr*, *state*, ***kwargs*)

Determine the categorization of state successors into stashes. The result should be a dict mapping stash names to the list of successor states that fall into that stash, or None as a stash name to use the original stash name.

If you would like to directly work with a *SimSuccessors* object, you can obtain it with `simgr.successors(state, **kwargs)`. This is not recommended, as it denies other hooks the opportunity to look at the successors. Therefore, the usual technique is to call `simgr.step_state(state, **kwargs)` and then mutate the returned dict before returning it yourself.

..note:: This takes precedence over the *filter* hook - *filter* is only applied to states returned from here in the None stash.

**Parameters**

- **simgr** (*angr.SimulationManager*)
- **state** (*angr.SimState*)

**successors**(*simgr*, *state*, ***kwargs*)

Perform the process of stepping a state forward, returning a SimSuccessors object.

To defer to the original succession procedure, return the result of `simgr.successors(state, **kwargs)`. Be careful about not calling this method (e.g. calling `project.factory.successors` manually) as it denies other hooks the opportunity to instrument the step. Instead, you can mutate the kwargs for the step before calling the original, and mutate the result before returning it yourself.

If the user provided a `successor_func` in their step or run command, it will appear here.

**Parameters**

- **simgr** (*angr.SimulationManager*)
- **state** (*angr.SimState*)

**complete**(*simgr*)

Return whether or not this manager has reached a "completed" state, i.e. `SimulationManager.run()` should halt.

This is the one hook which is *not* subject to the nesting rules of hooks. You should *not* call `simgr.complete`, you should make your own decision and return True or False. Each of the techniques' completion checkers will be called and the final result will be compted with `simgr.completion_mode`.

**Parameters**

**simgr** (*angr.SimulationManager*)

### 10.18.2 angr.exploration_techniques.bucketizer

**class** angr.exploration_techniques.bucketizer.**Bucketizer**

Bases: *ExplorationTechnique*

Loop bucketization: Pick log(n) paths out of n possible paths, and stash (or drop) everything else.

### 10.18.3 angr.exploration_techniques.common

angr.exploration_techniques.common.**condition_to_lambda**(*condition*, *default=False*)

Translates an integer, set, list or function into a lambda that checks if state's current basic block matches some condition.

**Parameters**

- **condition** – An integer, set, list or lambda to convert to a lambda.
- **default** – The default return value of the lambda (in case condition is None). Default: false.

**Returns**

A tuple of two items: a lambda that takes a state and returns the set of addresses that it matched from the condition, and a set that contains the normalized set of addresses to stop at, or None if no addresses were provided statically.

### 10.18.4 angr.exploration_techniques.dfs

**class** angr.exploration_techniques.dfs.**DFS**

Bases: *ExplorationTechnique*

Depth-first search.

Will only keep one path active at a time, any others will be stashed in the 'deferred' stash. When we run out of active paths to step, we take the longest one from deferred and continue.

**__init__**(*deferred_stash='deferred'*)

### 10.18.5 angr.exploration_techniques.directed_search

**class** angr.exploration_techniques.directed_search.**DirectedSearch**

Bases: *ExplorationTechnique*

Best-first search toward a target address, ranked by distance in a CFG.

After every step, the states in the stepped stash and in `deferred_stash` are ranked together by their distance to `target_addr`, and the `beam_width` closest stay in the stepped stash. The rest wait in `deferred_stash`,

so a deferred state comes back as soon as it is among the closest. Ties keep the earlier-deferred state first. The technique keeps `deferred_stash` sorted by distance.

The distance of a state is the fewest CFG edges from the block holding its address to the block holding the target. It is a heuristic: every block counts as one hop, and it ignores calling context, so from inside a function the shortest return to *any* caller counts. States whose address is not in the CFG, or that cannot reach the target, rank last.

A state that loops close to the target stays ahead of farther ones indefinitely; pair this technique with `LoopSeer` or `LengthLimiter` when that can happen. Use one instance per stepped stash: states in `deferred_stash` can move into whichever stash is stepped, and successors sent elsewhere with `target_stash` are not ranked.

**__init__**(*cfg*, *target_addr*, *beam_width=1*, *deferred_stash='directed_deferred'*)

**Parameters**

- **cfg** – A CFG analysis (e.g. `project.analyses.CFGFast()`) or its `CFGModel`.
- **target_addr** (`int`) – The address to steer toward. It need not start a block.
- **beam_width** (`int`) – How many of the closest states to keep after each step (at least 1).
- **deferred_stash** (`str`) – The stash for states that are not among the closest.

**Raises**

`ValueError` – If `beam_width` is below 1, or no CFG node contains `target_addr`.

**distance**(*addr*)

The CFG distance from `addr` to the target, or `inf` when `addr` is not in the CFG or cannot reach it.

**Return type**

`float`

**Parameters**

**addr** (*int*)

### 10.18.6 angr.exploration_techniques.director

**class** angr.exploration_techniques.director.**BaseGoal**

Bases: `object`

**REQUIRE_CFG_STATES = False**

**__init__**(*sort*)

**check**(*cfg*, *state*, *peek_blocks*)

**Parameters**

- **cfg** (*angr.analyses.CFGEmulated*) – An instance of CFGEmulated.
- **state** (*angr.SimState*) – The state to check.
- **peek_blocks** (*int*) – Number of blocks to peek ahead from the current point.

**Returns**

True if we can determine that this condition is definitely satisfiable if the path is taken, False otherwise.

**Return type**

bool

**check_state**(*state*)

Check if the current state satisfies the goal.

**Parameters**
**state** (*angr.SimState*) – The state to check.

**Returns**
True if it satisfies the goal, False otherwise.

**Return type**
bool

**class** angr.exploration_techniques.director.**ExecuteAddressGoal**

Bases: *BaseGoal*

A goal that prioritizes states reaching (or are likely to reach) certain address in some specific steps.

**__init__**(*addr*)

**check**(*cfg*, *state*, *peek_blocks*)

Check if the specified address will be executed

**Parameters**

- **cfg**
- **state**
- **peek_blocks** (*int*)

**Returns**

**Return type**
bool

**check_state**(*state*)

Check if the current address is the target address.

**Parameters**
**state** (*angr.SimState*) – The state to check.

**Returns**
True if the current address is the target address, False otherwise.

**Return type**
bool

**class** angr.exploration_techniques.director.**CallFunctionGoal**

Bases: *BaseGoal*

A goal that prioritizes states reaching certain function, and optionally with specific arguments. Note that constraints on arguments (and on function address as well) have to be identifiable on an accurate CFG. For example, you may have a CallFunctionGoal saying "call printf with the first argument being 'Hello, world'", and CFGEmulated must be able to figure our the first argument to printf is in fact "Hello, world", not some symbolic strings that will be constrained to "Hello, world" during symbolic execution (or simulation, however you put it).

**REQUIRE_CFG_STATES = True**

**__init__**(*function*, *arguments*)

**check**(*cfg*, *state*, *peek_blocks*)

Check if the specified function will be reached with certain arguments.

**Parameters**

- **cfg**
- **state**
- **peek_blocks**

**Returns**

**check_state**(*state*)

Check if the specific function is reached with certain arguments

**Parameters**
**state** (*angr.SimState*) – The state to check

**Returns**
True if the function is reached with certain arguments, False otherwise.

**Return type**
bool

**class** angr.exploration_techniques.director.**Director**

Bases: *ExplorationTechnique*

An exploration technique for directed symbolic execution.

A control flow graph (using CFGEmulated) is built and refined during symbolic execution. Each time the execution reaches a block that is outside of the CFG, the CFG recovery will be triggered with that state, with a maximum recovery depth (100 by default). If we see a basic block during state stepping that is not yet in the control flow graph, we go back to control flow graph recovery and "peek" more blocks forward.

When stepping a simulation manager, all states are categorized into three different categories:

- Might reach the destination within the peek depth. Those states are prioritized.
- Will not reach the destination within the peek depth. Those states are de-prioritized. However, there is a little chance for those states to be explored as well in order to prevent over-fitting.

**__init__**(*peek_blocks=100*, *peek_functions=5*, *goals=None*, *cfg_keep_states=False*, *goal_satisfied_callback=None*, *num_fallback_states=5*)

Constructor.

**step**(*simgr*, *stash='active'*, ***kwargs*)

**Parameters**

- **simgr**
- **stash**
- **kwargs**

**Returns**

**add_goal**(*goal*)

Add a goal.

**Parameters**
**goal** (BaseGoal) – The goal to add.

**Returns**
None

### 10.18.7 angr.exploration_techniques.driller_core

**class** angr.exploration_techniques.driller_core.**DrillerCore**

Bases: *ExplorationTechnique*

An exploration technique that symbolically follows an input looking for new state transitions.

It has to be used with Tracer exploration technique. Results are put in 'diverted' stash.

**__init__**(*trace*, *fuzz_bitmap=None*)

:param trace : The basic block trace. :type fuzz_bitmap: :param fuzz_bitmap: AFL's bitmap of state transitions. Defaults to saying every transition is worth satisfying.

### 10.18.8 angr.exploration_techniques.explorer

**class** angr.exploration_techniques.explorer.**Explorer**

Bases: *ExplorationTechnique*

Search for up to "num_find" paths that satisfy condition "find", avoiding condition "avoid". Stashes found paths into "find_stash' and avoided paths into "avoid_stash".

The "find" and "avoid" parameters may be any of:

- An address to find
- A set or list of addresses to find
- A function that takes a path and returns whether or not it matches.

If an angr CFG is passed in as the "cfg" parameter and "find" is either a number or a list or a set, then any paths which cannot possibly reach a success state without going through a failure state will be preemptively avoided.

If either the "find" or "avoid" parameter is a function returning a boolean, and a path triggers both conditions, it will be added to the find stash, unless "avoid_priority" is set to True.

**__init__**(*find=None*, *avoid=None*, *find_stash='found'*, *avoid_stash='avoid'*, *cfg=None*, *num_find=1*, *avoid_priority=False*)

### 10.18.9 angr.exploration_techniques.lengthlimiter

**class** angr.exploration_techniques.lengthlimiter.**LengthLimiter**

Bases: *ExplorationTechnique*

Length limiter on paths.

**__init__**(*max_length*, *drop=False*)

### 10.18.10 angr.exploration_techniques.local_loop_seer

**class** angr.exploration_techniques.local_loop_seer.**LocalLoopSeer**

Bases: *ExplorationTechnique*

LocalLoopSeer monitors exploration and maintains all loop-related data without relying on a control flow graph.

__init__(*bound=None*, *bound_reached=None*, *discard_stash='spinning'*)

**Parameters**

- **bound** – Limit the number of iterations a loop may be executed.
- **bound_reached** – If provided, should be a function that takes the LoopSeer and the succ_state. Will be called when loop execution reach the given bound. Default to moving states that exceed the loop limit to a discard stash.
- **discard_stash** – Name of the stash containing states exceeding the loop limit.

### 10.18.11 angr.exploration_techniques.loop_seer

class angr.exploration_techniques.loop_seer.**LoopSeer**

Bases: *ExplorationTechnique*

This exploration technique monitors exploration and maintains all loop-related data (well, currently it is just the loop trip counts, but feel free to add something else).

__init__(*cfg=None*, *functions=None*, *loops=None*, *use_header=False*, *bound=None*, *bound_reached=None*, *discard_stash='spinning'*, *limit_concrete_loops=True*)

**Parameters**

- **cfg** – Normalized CFG is required.
- **functions** – Function(s) containing the loop(s) to be analyzed.
- **loops** – Specific group of Loop(s) to be analyzed, if this is None we run the LoopFinder analysis.
- **use_header** – Whether to use header based trip counter to compare with the bound limit.
- **bound** – Limit the number of iterations a loop may be executed.
- **bound_reached** – If provided, should be a function that takes the LoopSeer and the succ_state. Will be called when loop execution reach the given bound. Default to moving states that exceed the loop limit to a discard stash.
- **discard_stash** – Name of the stash containing states exceeding the loop limit.
- **limit_concrete_loops** – If False, do not limit a loop back-edge if it is the only successor (Defaults to True to maintain the original behavior)

### 10.18.12 angr.exploration_techniques.manual_mergepoint

class angr.exploration_techniques.manual_mergepoint.**ManualMergepoint**

Bases: *ExplorationTechnique*

__init__(*address*, *wait_counter=10*, *prune=True*)

mark_nofilter(*simgr*, *stash*)

mark_okfilter(*simgr*, *stash*)

### 10.18.13 angr.exploration_techniques.memory_watcher

class angr.exploration_techniques.memory_watcher.**MemoryWatcher**

Bases: *ExplorationTechnique*

Memory Watcher

**Parameters**

- **min_memory** (*int*, optional) – Minimum amount of free memory in MB before stopping execution (default: 95% memory use)
- **memory_stash** (*str*, optional) – What to call the low memory stash (default: 'lowmem')

At each step, keep an eye on how much memory is left on the system. Stash off states to effectively stop execution if we're below a given threshold.

**__init__**(*min_memory=512*, *memory_stash='lowmem'*)

### 10.18.14 angr.exploration_techniques.oppologist

class angr.exploration_techniques.oppologist.**Oppologist**

Bases: *ExplorationTechnique*

The Oppologist is an exploration technique that forces uncooperative code through qemu.

**__init__**()

### 10.18.15 angr.exploration_techniques.slicecutor

class angr.exploration_techniques.slicecutor.**Slicecutor**

Bases: *ExplorationTechnique*

The Slicecutor is an exploration that executes provided code slices.

**__init__**(*annotated_cfg*, *force_taking_exit=False*, *force_sat=False*)

All parameters except *annotated_cfg* are optional.

**Parameters**

- **annotated_cfg** – The AnnotatedCFG that provides the code slice.
- **force_taking_exit** – Set to True if you want to create a successor based on our slice in case of unconstrained successors.
- **force_sat** (bool) – If a branch specified by the slice is unsatisfiable, set this option to True if you want to force it to be satisfiable and be taken anyway.

### 10.18.16 angr.exploration_techniques.spiller

class angr.exploration_techniques.spiller.**PickledStatesBase**

Bases: object

The base class of pickled states

**sort**()

Sort pickled states.

**add**(*prio*, *sid*)

Add a newly pickled state.

**Parameters**

- **prio** (*int*) – Priority of the state.
- **sid** (*str*) – Persistent ID of the state.

**Returns**
None

**pop_n**(*n*)

Pop the top N states.

**Parameters**
**n** (*int*) – Number of states to take.

**Returns**
A list of states.

**class** angr.exploration_techniques.spiller.**PickledStatesList**

Bases: *PickledStatesBase*

List-backed pickled state storage.

**__init__**()

**class** angr.exploration_techniques.spiller.**PickledStatesDb**

Bases: *PickledStatesBase*

Database-backed pickled state storage.

**__init__**(*db_str='sqlite:///:memory:'*)

**get_recent_n**(*n*, *stash='spilled'*)

**count**()

**class** angr.exploration_techniques.spiller.**Spiller**

Bases: *ExplorationTechnique*

Automatically spill states out. It can spill out states to a different stash, spill them out to ANA, or first do the former and then (after enough states) the latter.

**__init__**(*src_stash='active'*, *min=5*, *max=10*, *staging_stash='spill_stage'*, *staging_min=10*, *staging_max=20*, *pickle_callback=None*, *unpickle_callback=None*, *post_pickle_callback=None*, *priority_key=None*, *vault=None*, *states_collection=None*)

Initializes the spiller.

**Parameters**

- **max** – the number of states that are *not* spilled
- **src_stash** – the stash from which to spill states (default: active)
- **staging_stash** – the stash *to* which to spill states (default: "spill_stage")
- **staging_max** – the number of states that can be in the staging stash before things get spilled to ANA (default: None. If staging_stash is set, then this means unlimited, and ANA will not be used).

- **priority_key** – a function that takes a state and returns its numerical priority (MAX_INT is lowest priority). By default, self.state_priority will be used, which prioritizes by object ID.
- **vault** – an angr.Vault object to handle storing and loading of states. If not provided, an angr.vaults.VaultShelf will be created with a temporary file.

**static state_priority**(*state*)

### 10.18.17 angr.exploration_techniques.spiller_db

**class** angr.exploration_techniques.spiller_db.**PickledState**

Bases: Base

**id**

**priority**

**taken**

**stash**

**timestamp**

**__init__**(***kwargs*)

A simple constructor that allows initialization from kwargs.

Sets attributes on the constructed instance using the names and values in **kwargs**.

Only keys that are present as attributes of the instance's class are allowed. These could be, for example, any mapped columns or relationships.

### 10.18.18 angr.exploration_techniques.stochastic

**class** angr.exploration_techniques.stochastic.**StochasticSearch**

Bases: *ExplorationTechnique*

Stochastic Search.

Will only keep one path active at a time, any others will be discarded. Before each pass through, weights are randomly assigned to each basic block. These weights form a probability distribution for determining which state remains after splits. When we run out of active paths to step, we start again from the start state.

**__init__**(*start_state*, *restart_prob=0.0001*)

**Parameters**

- **start_state** – The initial state from which exploration stems.
- **restart_prob** – The probability of randomly restarting the search (default 0.0001).

### 10.18.19 angr.exploration_techniques.stub_stasher

**class** angr.exploration_techniques.stub_stasher.**StubStasher**

Bases: *ExplorationTechnique*

Stash states that reach a stub SimProcedure.

**static post_filter**(*state*)

### 10.18.20 angr.exploration_techniques.suggestions

angr.exploration_techniques.suggestions.**ast_weight**(*ast*, *memo=None*)

**class** angr.exploration_techniques.suggestions.**Suggestions**

Bases: *ExplorationTechnique*

An exploration technique which analyzes failure cases and logs suggestions for how to mitigate them in future analyses.

**__init__**()

**static report**(*state*, *event*)

### 10.18.21 angr.exploration_techniques.tech_builder

**class** angr.exploration_techniques.tech_builder.**TechniqueBuilder**

Bases: *ExplorationTechnique*

This meta technique could be used to hook a couple of simulation manager methods without actually creating a new exploration technique, for example:

class SomeComplexAnalysis(Analysis):

**def do_something():**
simgr = self.project.factory.simulation_manager() simgr.use_tech(ProxyTechnique(step_state=self._step_state)) simgr.run()

**def _step_state(self, state):**
# Do stuff! pass

In the above example, the _step_state method can access all the necessary stuff, hidden in the analysis instance, without passing that instance to a one-shot-styled exploration technique.

**__init__**(*setup=None*, *step_state=None*, *step=None*, *successors=None*, *filter=None*, *selector=None*, *complete=None*)

### 10.18.22 angr.exploration_techniques.threading

**class** angr.exploration_techniques.threading.**Threading**

Bases: *ExplorationTechnique*

Enable multithreading.

This is only useful in paths where a lot of time is taken inside z3, doing constraint solving. This is because of python's GIL, which says that only one thread at a time may be executing python code.

**__init__**(*threads=8*, *local_stash='thread_local'*)

**inner_step**(*state*, *simgr*, ***kwargs*)

### 10.18.23 angr.exploration_techniques.timeout

**class** angr.exploration_techniques.timeout.**Timeout**

Bases: *ExplorationTechnique*

Timeout exploration technique that stops an active exploration if the run time exceeds a predefined timeout

**__init__**(*timeout=None*)

### 10.18.24 angr.exploration_techniques.tracer

**class** angr.exploration_techniques.tracer.**TracingMode**

Bases: object

**Variables**

- **Strict** – Strict mode, the default mode, where an exception is raised immediately if tracer's path deviates from the provided trace.
- **Permissive** – Permissive mode, where tracer attempts to force the path back to the provided trace when a deviation happens. This does not always work, especially when the cause of deviation is related to input that will later be used in exploit generation. But, it might work magically sometimes.
- **CatchDesync** – CatchDesync mode, catch desync because of sim_procedures. It might be a sign of something interesting.

**Strict = 'strict'**

**Permissive = 'permissive'**

**CatchDesync = 'catch_desync'**

**exception** angr.exploration_techniques.tracer.**TracerDesyncError**

Bases: *AngrTracerError*

An error class to report tracing Tracing desyncronization error

**class** angr.exploration_techniques.tracer.**RepHook**

Bases: object

Hook rep movs/stos to speed up constraint solving TODO: This should be made an exploration technique later

**__init__**(*mnemonic*)

**run**(*state*)

**class** angr.exploration_techniques.tracer.**Tracer**

Bases: *ExplorationTechnique*

An exploration technique that follows an angr path with a concrete input. The tracing result is the state at the last address of the trace, which can be found in the 'traced' stash.

If the given concrete input makes the program crash, you should provide crash_addr, and the crashing state will be found in the 'crashed' stash.

**Parameters**

- **trace** (list[int]) – The basic block trace.
- **resiliency** – Should we continue to step forward even if qemu and angr disagree?
- **keep_predecessors** – Number of states before the final state we should log.
- **crash_addr** – If the trace resulted in a crash, provide the crashing instruction pointer here, and the 'crashed' stash will be populated with the crashing state.
- **syscall_data** – Data related to various syscalls recorded by tracer for replaying
- **copy_states** – Whether COPY_STATES should be enabled for the tracing state. It is off by default because most tracing workloads benefit greatly from not performing copying. You want to enable it if you want to see the missed states. It will be re-added for the last 2% of

the trace in order to set the predecessors list correctly. If you turn this on you may want to enable the LAZY_SOLVES option.

- **mode** – Tracing mode.
- **aslr** – Whether there are aslr slides. if not, tracer uses trace address as state address.
- **follow_unsat** – Whether unsatisfiable states should be treated as potential successors or not.

**Variables**
**predecessors** (list[*SimState*]) – A list of states in the history before the final state.

**__init__**(*trace*, *resiliency=False*, *keep_predecessors=1*, *crash_addr=None*, *syscall_data=None*, *copy_states=False*, *fast_forward_to_entry=True*, *mode='strict'*, *aslr=True*, *follow_unsat=False*)

**Parameters**
**trace** (*list[int]*)

**predecessors: list[*SimState*]**

**set_fd_data**(*fd_data*)

Set concrete bytes of various fds read by the program

**Parameters**
**fd_data** (*dict[int, bytes]*)

**classmethod crash_windup**(*state*, *crash_addr*)

### 10.18.25 angr.exploration_techniques.unique

**class** angr.exploration_techniques.unique.**UniqueSearch**

Bases: *ExplorationTechnique*

Unique Search.

Will only keep one path active at a time, any others will be deferred. The state that is explored depends on how unique it is relative to the other deferred states. A path's uniqueness is determined by its average similarity between the other (deferred) paths. Similarity is calculated based on the supplied *similarity_func*, which by default is: The (L2) distance between the counts of the state addresses in the history of the path.

**__init__**(*similarity_func=None*, *deferred_stash='deferred'*)

**Parameters**

- **similarity_func** – How to calculate similarity between two states.
- **deferred_stash** – Where to store the deferred states.

**static similarity**(*state_a*, *state_b*)

The (L2) distance between the counts of the state addresses in the history of the path. :type state_a: :param state_a: The first state to compare :type state_b: :param state_b: The second state to compare

**static sequence_matcher_similarity**(*state_a*, *state_b*)

The *difflib.SequenceMatcher* ratio between the state addresses in the history of the path. :type state_a: :param state_a: The first state to compare :type state_b: :param state_b: The second state to compare

### 10.18.26 angr.exploration_techniques.veritesting

**class** angr.exploration_techniques.veritesting.**Veritesting**

Bases: *ExplorationTechnique*

Enable veritesting. This technique, described in a paper[1] from CMU, attempts to address the problem of state explosions in loops by performing smart merging.

[1] https://users.ece.cmu.edu/~aavgerin/papers/veritesting-icse-2014.pdf

**__init__**(***options*)

## 10.19 angr.factory

**class** angr.factory.**AngrObjectFactory**

Bases: object

This factory provides access to important analysis elements.

**__init__**(*project*, *default_engine=None*)

**Parameters**
**default_engine** (type[SimEngine] | None)

**default_engine_factory:** type[*SimEngine*]

**project:** *Project*

**procedure_engine:** *ProcedureEngine*

**property default_engine**

**snippet**(*addr*, *jumpkind=None*, ***block_opts*)

**successors**(**args*, *engine=None*, ***kwargs*)

Perform execution using an engine. Generally, return a SimSuccessors object classifying the results of the run.

**Parameters**

- **state** – The state to analyze
- **engine** – The engine to use. If not provided, will use the project default.
- **addr** – optional, an address to execute at instead of the state's ip
- **jumpkind** – optional, the jumpkind of the previous exit
- **inline** – This is an inline execution. Do not bother copying the state.

Additional keyword arguments will be passed directly into each engine's process method.

**blank_state**(***kwargs*)

Returns a mostly-uninitialized state object. All parameters are optional.

**Parameters**

- **addr** – The address the state should start at instead of the entry point.
- **initial_prefix** – If this is provided, all symbolic registers will hold symbolic values with names prefixed by this string.
- **fs** – A dictionary of file names with associated preset SimFile objects.

- **concrete_fs** – bool describing whether the host filesystem should be consulted when opening files.
- **chroot** – A path to use as a fake root directory, Behaves similarly to a real chroot. Used only when concrete_fs is set to True.
- **kwargs** – Any additional keyword args will be passed to the SimState constructor.

**Returns**
The blank state.

**Return type**
*SimState*

**entry_state**(***kwargs*)

Returns a state object representing the program at its entry point. All parameters are optional.

**Parameters**

- **addr** – The address the state should start at instead of the entry point.
- **initial_prefix** – If this is provided, all symbolic registers will hold symbolic values with names prefixed by this string.
- **fs** – a dictionary of file names with associated preset SimFile objects.
- **concrete_fs** – boolean describing whether the host filesystem should be consulted when opening files.
- **chroot** – a path to use as a fake root directory, behaves similar to a real chroot. used only when concrete_fs is set to True.
- **argc** – a custom value to use for the program's argc. May be either an int or a bitvector. If not provided, defaults to the length of args.
- **args** – a list of values to use as the program's argv. May be mixed strings and bitvectors.
- **env** – a dictionary to use as the environment for the program. Both keys and values may be mixed strings and bitvectors.

**Returns**
The entry state.

**Return type**
*SimState*

**full_init_state**(***kwargs*)

Very much like *entry_state()*, except that instead of starting execution at the program entry point, execution begins at a special SimProcedure that plays the role of the dynamic loader, calling each of the initializer functions that should be called before execution reaches the entry point.

It can take any of the arguments that can be provided to `entry_state`, except for `addr`.

**call_state**(*addr*, **args*, ***kwargs*)

Returns a state object initialized to the start of a given function, as if it were called with given parameters.

**Parameters**

- **addr** – The address the state should start at instead of the entry point.
- **args** – Any additional positional arguments will be used as arguments to the function call.
- **base_state** – Use this SimState as the base for the new state instead of a blank state.
- **cc** – Optionally provide a SimCC object to use a specific calling convention.

- **ret_addr** – Use this address as the function's return target.
- **stack_base** – An optional pointer to use as the top of the stack, circa the function entry point
- **alloc_base** – An optional pointer to use as the place to put excess argument data
- **grow_like_stack** – When allocating data at alloc_base, whether to allocate at decreasing addresses
- **toc** – The address of the table of contents for ppc64
- **initial_prefix** – If this is provided, all symbolic registers will hold symbolic values with names prefixed by this string.
- **fs** – A dictionary of file names with associated preset SimFile objects.
- **concrete_fs** – bool describing whether the host filesystem should be consulted when opening files.
- **chroot** – A path to use as a fake root directory, Behaves similarly to a real chroot. Used only when concrete_fs is set to True.
- **kwargs** – Any additional keyword args will be passed to the SimState constructor.

**Returns**
The state at the beginning of the function.

**Return type**
*SimState*

The idea here is that you can provide almost any kind of python type in *args* and it'll be translated to a binary format to be placed into simulated memory. Lists (representing arrays) must be entirely elements of the same type and size, while tuples (representing structs) can be elements of any type and size. If you'd like there to be a pointer to a given value, wrap the value in a *SimCC.PointerWrapper*. Any value that can't fit in a register will be automatically put in a PointerWrapper.

If stack_base is not provided, the current stack pointer will be used, and it will be updated. If alloc_base is not provided, the current stack pointer will be used, and it will be updated. You might not like the results if you provide stack_base but not alloc_base.

grow_like_stack controls the behavior of allocating data at alloc_base. When data from args needs to be wrapped in a pointer, the pointer needs to point somewhere, so that data is dumped into memory at alloc_base. If you set alloc_base to point to somewhere other than the stack, set grow_like_stack to False so that sequential allocations happen at increasing addresses.

**simulation_manager**(*thing=None*, ***kwargs*)

Constructs a new simulation manager.

**Parameters**

- **thing** (list[*SimState*] | *SimState* | None) – What to put in the new SimulationManager's active stash (either a SimState or a list of SimStates).
- **kwargs** – Any additional keyword arguments will be passed to the SimulationManager constructor

**Returns**
The new SimulationManager

**Return type**
*SimulationManager*

Many different types can be passed to this method:

- If nothing is passed in, the SimulationManager is seeded with a state initialized for the program entry point, i.e. *entry_state()*.
- If a `SimState` is passed in, the SimulationManager is seeded with that state.
- If a list is passed in, the list must contain only SimStates and the whole list will be used to seed the SimulationManager.

**simgr**(**args*, ***kwargs*)

Alias for *simulation_manager* to save our poor fingers

**callable**(*addr*, *prototype=None*, *concrete_only=False*, *perform_merge=True*, *base_state=None*, *toc=None*, *cc=None*, *add_options=None*, *remove_options=None*, *techniques=None*, *step_limit=None*)

A Callable is a representation of a function in the binary that can be interacted with like a native python function.

**Parameters**

- **addr** (`int` | *Function*) – The address of the function to use. If you pass in the function object, we will take its addr.
- **prototype** – The prototype of the call to use, as a string or a SimTypeFunction
- **concrete_only** – Throw an exception if the execution splits into multiple states
- **perform_merge** – Merge all result states into one at the end (only relevant if concrete_only=False)
- **base_state** – The state from which to do these runs
- **toc** – The address of the table of contents for ppc64
- **cc** – The SimCC to use for a calling convention
- **step_limit** (`int` | `None`) – The maximum number of blocks that Callable will execute before pruning the path.
- **techniques** (*list[ExplorationTechnique] | None*)

**Returns**
A Callable object that can be used as a interface for executing guest code like a python function.

**Return type**
*angr.callable.Callable*

**cc**()

Return a SimCC (calling convention) parameterized for this project.

Relevant subclasses of SimFunctionArgument are SimRegArg and SimStackArg, and shortcuts to them can be found on this *cc* object.

For stack arguments, offsets are relative to the stack pointer on function entry.

**function_prototype**()

Return a default function prototype parameterized for this project and SimOS.

**block**(*addr*, *size=None*, *max_size=None*, *byte_string=None*, *thumb=False*, *backup_state=None*, *extra_stop_points=None*, *opt_level=None*, *num_inst=None*, *traceflags=0*, *insn_bytes=None*, *strict_block_end=None*, *collect_data_refs=False*, *cross_insn_opt=True*, *load_from_ro_regions=False*, *const_prop=False*, *initial_regs=None*, *skip_stmts=False*)

**Overloads**

- **addr** (int), **size** = None, **max_size** = None, **byte_string** = None, **thumb** = False, **backup_state** = None, **extra_stop_points** = None, **opt_level** = None, **num_inst** = None, **traceflags** = 0, **insn_bytes** = None, **strict_block_end** = None, **collect_data_refs** = False, **cross_insn_opt** = True, **load_from_ro_regions** = False, **const_prop** = False, **initial_regs** = None, **skip_stmts** = False →
- **addr** (), **size** = None, **max_size** = None, **byte_string** = None, **thumb** = False, **backup_state** = None, **extra_stop_points** = None, **opt_level** = None, **num_inst** = None, **traceflags** = 0, **insn_bytes** = None, **strict_block_end** = None, **collect_data_refs** = False, **load_from_ro_regions** = False, **const_prop** = False, **cross_insn_opt** = True, **skip_stmts** = False →

**fresh_block**(*addr*, *size*, *backup_state=None*)

## 10.20 angr.flirt

angr.flirt.**FS**

alias of *FlirtSignature*

**class** angr.flirt.**FlirtSignature**

Bases: object

This class describes a FLIRT signature without any internal data that is only available after parsing.

**__init__**(*arch*, *platform*, *sig_name*, *sig_path*, *unique_strings=None*, *compiler=None*, *compiler_version=None*, *os_name=None*, *os_version=None*)

**Parameters**

- **arch** (*str*)
- **platform** (*str*)
- **sig_name** (*str*)
- **sig_path** (*str*)
- **unique_strings** (*set[str] | None*)
- **compiler** (*str | None*)
- **compiler_version** (*str | None*)
- **os_name** (*str | None*)
- **os_version** (*str | None*)

angr.flirt.**load_signature**(*sig_path*, *meta_path=None*)

Load a single FLIRT signature from a specific path.

**Parameters**

- **sig_path** (str) – Location of the FLIRT signature.
- **meta_path** (*str | None*)

**Return type**

tuple[str, *FlirtSignature*] | None

**Returns**

A FlirtSignature object if loading was successful, None otherwise.

angr.flirt.**load_signatures**(*path*, *ignore=None*)

Recursively load all FLIRT signatures under a specific path.

**Parameters**

- **path** (str) – Location of FLIRT signatures.
- **ignore** (list[str] | None) – A list of signature directory path prefixes to ignore. If None, a default list of signatures will be loaded.

**Return type**
None

### Submodules

*build_sig*

## 10.20.1 angr.flirt.build_sig

angr.flirt.build_sig.**get_basic_info**(*ar_path*)

Get basic information of the archive file.

**Return type**
dict[str, str]

**Parameters**
**ar_path** (*str*)

angr.flirt.build_sig.**get_unique_strings**(*ar_path*)

For Linux libraries, this method requires ar (from binutils), nm (from binutils), and strings.

**Return type**
list[str]

**Parameters**
**ar_path** (*str*)

angr.flirt.build_sig.**run_pelf**(*pelf_path*, *ar_path*, *output_path*)

**Parameters**

- **pelf_path** (*str*)
- **ar_path** (*str*)
- **output_path** (*str*)

angr.flirt.build_sig.**run_sigmake**(*sigmake_path*, *sig_name*, *pat_path*, *sig_path*)

**Parameters**

- **sigmake_path** (*str*)
- **sig_name** (*str*)
- **pat_path** (*str*)
- **sig_path** (*str*)

angr.flirt.build_sig.**process_exc_file**(*exc_path*)

We are doing the stupidest thing possible: For each batch of conflicts, we pick the most likely result based on a set of predefined rules.

TODO: Add caller-callee-based de-duplication.

**Parameters**
**exc_path** (*str*)

angr.flirt.build_sig.**main**()

## 10.21 angr.go

### Submodules

| | |
|---|---|
| *analyses* | |
| *codegen_builtins* | Rendering of Go builtins and operator-like statements that the runtime rewriter encodes as AIL `Call` expressions. |
| *codegen_builtins_values* | Rendering of builtin-call expressions produced by GoBuiltinRewriter that are not plain `name(args)`: slice expressions (`s[i:j]`) and calls that carry a comment about what could not be recovered. |
| *knowledge_plugins* | |
| *optimization_passes* | |
| *runtime_types* | |
| *signature* | Language-level Go function signatures and named-type descriptions. |
| *sim_type* | Go-flavored SimTypes. |
| *type_parser* | Parse canonical Go type strings (see angr.go.signature) into Go SimTypes. |
| *typehoon* | |
| *utils* | |

### 10.21.1 angr.go.analyses

#### Submodules

| | |
|---|---|
| *block_scan* | Raw-AIL block scanning shared by the project-level Go analyses: lift blocks straight from VEX (no SSA, no simplification) and track which constants and call results the machine registers hold. |
| *dwarf_signatures* | Read Go function signatures and named types from the DWARF that `cmd/compile/cmd/link` emit. |
| *go_globals_recovery* | |
| *package_variables* | Type package-level variables from their initializers. |
| *runtime_globals* | Locate the Go runtime's own package-level variables by shape when no data symbol names them: |
| *type_descriptors* | Read Go runtime type descriptors (`internal/abi.Type`) and itabs out of a binary's `runtime.moduledata`. |

### angr.go.analyses.block_scan

Raw-AIL block scanning shared by the project-level Go analyses: lift blocks straight from VEX (no SSA, no simplification) and track which constants and call results the machine registers hold.

**class** angr.go.analyses.block_scan.**RegisterEnv**

Bases: object

What the machine registers (and VEX temporaries) hold inside one block: constants, typed call results and closure-context offsets. Keys are `("r", offset)` / `("t", index)`.

**__init__**(*arch*, *values=None*)

**Parameters**
**values** (*dict | None*)

**arch**

**values:** dict[tuple, tuple]

**copy**()

**Return type**
*RegisterEnv*

**merge**(*other*)

Meet of two environments: only agreeing register values survive (temporaries are block-local).

**Return type**
*RegisterEnv*

**Parameters**
**other** (RegisterEnv)

**registers**()

**Return type**
dict[int, tuple]

**eval**(*expr*)

The value of `expr`, or None.

**store**(*addr_expr*, *data_expr*, *size*)

Remember a word stored into a stack slot.

**Return type**
None

**Parameters**
**size** (*int*)

**assign**(*stmt*)

**Return type**
None

**Parameters**
**stmt** (Assignment)

**clear_call_clobbers**(*keep=()*)

Forget every register except the stack pointer and `keep` (offsets), and every temporary.

**Return type**
None

**Parameters**
**keep** (*Iterable[int]*)

angr.go.analyses.block_scan.**allocator**(*name*)

`(type prefix, descriptor argument index)` for a runtime allocator, else None.

**Return type**
tuple[str, int | None] | None

**Parameters**
**name** (*str | None*)

angr.go.analyses.block_scan.**block_successors**(*project*, *addr*, *size=None*)

Direct successors of a block: its exits and, after a call, the return address.

**Return type**
list[int]

**Parameters**

- **project** (Project)
- **addr** (*int*)
- **size** (*int | None*)

angr.go.analyses.block_scan.**call_target**(*stmt*)

**Return type**
int | None

angr.go.analyses.block_scan.**callee_name**(*project*, *addr*)

**Return type**
str | None

**Parameters**

- **project** (Project)
- **addr** (*int*)

angr.go.analyses.block_scan.**function_blocks**(*project*, *addr*, *limit=4096*)

Block addresses of the function at `addr` with their successor lists: the CFG's function graph when the function is known, else a bounded walk over direct jumps from the entry.

**Return type**
tuple[list[int], dict[int, list[int]]]

**Parameters**

- **project** (Project)
- **addr** (*int*)
- **limit** (*int*)

angr.go.analyses.block_scan.**is_function_addr**(*project*, *addr*)

`addr` starts a function known to the CFG or to the (pclntab-derived) symbol table.

**Return type**
bool

**Parameters**

- **project** (Project)
- **addr** (*int*)

angr.go.analyses.block_scan.**is_return**(*stmt*)

**Return type**
bool

angr.go.analyses.block_scan.**lift_ail**(*project*, *addr*, *size=None*, *manager=None*)

The raw AIL statements of the block at addr, or [] when it cannot be lifted.

**Return type**
list

**Parameters**

- **project** (Project)
- **addr** (*int*)
- **size** (*int | None*)

angr.go.analyses.block_scan.**loads_in**(*expr*, *out*)

Collect every Load below expr (depth first).

**Return type**
None

**Parameters**
**out** (*list*)

### angr.go.analyses.dwarf_signatures

Read Go function signatures and named types from the DWARF that cmd/compile/cmd/link emit.

Only compile units produced by Go cmd/compile are read. Type strings are taken from the Go-spelled DW_AT_name of the type DIEs and normalized to the canonical syntax of *angr.go.signature*.

angr.go.analyses.dwarf_signatures.**read_go_dwarf_signatures**(*project*)

Read Go function signatures and named types from the DWARF of the main object. Returns an empty set when the binary has no DWARF or its DWARF was not produced by the Go toolchain.

**Return type**
*GoSignatureSet*

**Parameters**
**project** (Project)

### angr.go.analyses.go_globals_recovery

**class** angr.go.analyses.go_globals_recovery.**GoGlobalsRecovery**

Bases: *Analysis*

Recover Go package-level variables without data symbols and record them in kb.go_globals: the runtime's own globals located by shape (*angr.go.analyses.runtime_globals*), then the variables typed from their initializers (*angr.go.analyses.package_variables*). Requires a CFG; a no-op on non-Go binaries.

Supports progress_callback and low_priority, so a GUI can run it in the background.

__init__(*low_priority=False*)

**Parameters**
**low_priority** (bool) – Run in the background: periodically release the GIL.

### angr.go.analyses.package_variables

Type package-level variables from their initializers.

Constant-initialized variables live in .data and need no code, so everything a package initializer (pkg.init, pkg.init.N) and main.main store into a global is a computed value whose shape names its type: a runtime type descriptor or itab word followed by a data word (an interface), an allocator result (newobject -> *T, makeslice -> []T, makemap -> map[K]V), a read-only pointer plus a length (string), a static funcval (a func), or the result registers of a call with a known Go signature. The scan works on raw AIL with a per-register environment; no SSA or simplification is needed.

angr.go.analyses.package_variables.**initializer_package**(*name*)

The package of an initializer (pkg.init, pkg.init.N, main.main); None for anything else.

**Return type**
str | None

**Parameters**
**name** (*str*)

angr.go.analyses.package_variables.**infer_package_variables**(*project*, *on_initializer=None*)

Package-level variables typed from the stores in the binary's initializers, named pkg.var_N.

**Return type**
list[*GoVariable*]

**Parameters**

- **project** (Project)
- **on_initializer** (Callable[[int, int], None] | None)

### angr.go.analyses.runtime_globals

Locate the Go runtime's own package-level variables by shape when no data symbol names them:

- runtime.writeBarrier: the word every compiled pointer store tests right before calling gcWriteBarrierN;
- runtime.zerobase: the address mallocgc returns for a zero-size allocation;
- runtime.staticuint64s: the read-only table [256]uint64{0, 1, 2, ...} small boxed integers point into;
- runtime.firstmoduledata: the moduledata the type-descriptor reader already found.

angr.go.analyses.runtime_globals.**find_runtime_globals**(*project*)

Every runtime global recognized by shape, keyed by its Go name.

**Return type**
dict[str, *GoVariable*]

**Parameters**
**project** (Project)

angr.go.analyses.runtime_globals.**find_staticuint64s**(*project*)

**Return type**
int | None

**Parameters**
**project** (Project)

angr.go.analyses.runtime_globals.**find_write_barrier**(*project*)

The address tested by the conditional block in front of the write-barrier calls in the CFG.

**Return type**
int | None

**Parameters**
**project** (Project)

angr.go.analyses.runtime_globals.**find_zerobase**(*project*)

`mallocgc` returns `&zerobase` from a block that only loads the address and returns.

**Return type**
int | None

**Parameters**
**project** (Project)

angr.go.analyses.runtime_globals.**is_readonly_data**(*project*, *addr*)

`addr` lies in a read-only, non-code region of the main object.

**Return type**
bool

**Parameters**

- **project** (Project)
- **addr** (*int*)

angr.go.analyses.runtime_globals.**is_writable_data**(*project*, *addr*)

`addr` lies in a writable, non-executable region of the main object.

**Return type**
bool

**Parameters**

- **project** (Project)
- **addr** (*int*)

angr.go.analyses.runtime_globals.**runtime_global_addr**(*project*, *name*, *kb=None*)

The address of a runtime global: its data symbol, else the shape-located one (stripped/PE binaries).

**Return type**
int | None

**Parameters**

- **project** (Project)
- **name** (*str*)

### angr.go.analyses.type_descriptors

Read Go runtime type descriptors (`internal/abi.Type`) and itabs out of a binary's `runtime.moduledata`.

This is the DWARF-less counterpart of *angr.go.analyses.dwarf_signatures*: the descriptors are the ground truth for the layout of every type in this binary. Type strings follow the canonical syntax of *angr.go.signature*; named types are qualified with the full import path taken from the descriptor's `UncommonType.PkgPath`.

Layouts handled (`src/runtime/symtab.go` and `src/internal/abi/type.go`):

- go1.20 .. go1.25: `moduledata.typelinks` ([]int32 offsets from `types`) and `itablinks` ([]*itab).
- go1.26+: `typedesclen` / `itaboffset` / `itabsize` describe contiguous runs of descriptors and itabs that are walked with `Type.DescriptorSize`; `epclntab` was inserted after `gofunc`.
- go1.18 / go1.19 (no `covctrs`) are accepted as well since the descriptor layout is identical, except that before go1.19 a struct field's offset word is `offsetAnon` (`offset << 1 | embedded`).

**class** angr.go.analyses.type_descriptors.**GoTypeDescriptors**

Bases: object

The runtime type descriptors of one binary.

**Variables**

- **go_version** – The Go release the binary was built with, when identifiable.
- **types** – Every named type as a GoNamedType record (only `types` is filled).
- **addr_to_name** – Descriptor address -> canonical Go type string.
- **name_to_addr** (dict[str, int]) – The reverse map (first descriptor wins).
- **itabs** – itab address -> (interface type name, concrete type name).
- **moduledata_addr** – Address of `runtime.firstmoduledata`, or None when none was found.
- **types_addr** – `moduledata.types`: the base that every NameOff/TypeOff (and DWARF's `DW_AT_go_runtime_type`) is relative to.

The eager walk covers everything reachable from the typelinks and itabs; descriptors that only code references (anonymous interfaces of type assertions, map buckets, ...) are parsed on demand by *resolve()*.

**__init__**(*go_version=None*, *goarch=None*, *types=None*, *addr_to_name=None*, *itabs=None*, *moduledata_addr=None*, *types_addr=None*, *reader=None*, *methods=None*)

**Parameters**

- **go_version** (*str | None*)
- **goarch** (*str | None*)
- **types** (GoSignatureSet | *None*)
- **addr_to_name** (*dict[int, str] | None*)
- **itabs** (*dict[int, tuple[str, str]] | None*)
- **moduledata_addr** (*int | None*)
- **types_addr** (*int | None*)
- **reader** (*_Reader | None*)
- **methods** (*dict[int, tuple[str, str, str]] | None*)

**methods:** dict[int, tuple[str, str, str]]

**go_version**

**types**

**addr_to_name**

**name_to_addr:** dict[str, int]

**itabs**

**moduledata_addr**

**types_addr**

**resolve**(*addr*)

The type string of the descriptor at addr, parsing it on demand when no typelink reached it.

**Return type**
str | None

**Parameters**
**addr** (*int*)

**resolve_itab**(*addr*)

**Return type**
tuple[str, str] | None

**Parameters**
**addr** (*int*)

angr.go.analyses.type_descriptors.**read_go_type_descriptors**(*project*, *use_cache=True*)

Parse the runtime type descriptors and itabs of the main object. Returns an empty result when the binary has no Go moduledata. Results are cached per binary within the process.

**Return type**
*GoTypeDescriptors*

**Parameters**

- **project** (Project)
- **use_cache** (*bool*)

### 10.21.2 angr.go.codegen_builtins

Rendering of Go builtins and operator-like statements that the runtime rewriter encodes as AIL `Call` expressions.

A rewritten call has a plain-string target and may carry a `go_render` tag that selects one of the operator forms below (the argument layout is fixed per kind). Calls without the tag render as `name(args)` by the regular call printer, which also prints the `go_type_args` tag (a list of Go type strings) before the arguments, so `Call("make", [n], go_type_args=["chan int"])` renders as `make(chan int, n)`.

`go_render` kinds:

- `"index"`: `[m, k]` -> `m[k]` (also for the tuple-valued `v, ok = m[k]` form; the destination is the assignment's left-hand side)
- `"assign"`: `[m, k, v]` -> `m[k] = v`
- `"send"`: `[c, v]` -> `c <- v`
- `"recv"`: `[c]` -> `<-c`
- `"go"`: `[f, args...]` -> `go f(args...)`
- `"defer"`: `[f, args...]` -> `defer f(args...)`
- `"concat"`: `[a, b]` -> `a + b` (string concatenation)

- `"closure"`: `[f, captures...]` -> `f{X0: a, X1: b}` (the closure record of `f`; the field names come from the `go_capture_names` tag), or just `f` without captures

angr.go.codegen_builtins.**render_builtin_call**(*call*)

Chunks for a codegen call node carrying a `go_render` tag, or None when the node is a regular call.

**Return type**
Iterator[tuple[str, object]] | None

### 10.21.3 angr.go.codegen_builtins_values

Rendering of builtin-call expressions produced by GoBuiltinRewriter that are not plain `name(args)`: slice expressions (`s[i:j]`) and calls that carry a comment about what could not be recovered.

angr.go.codegen_builtins_values.**call_tag**(*call*, *name*, *default=None*)

A tag of a codegen call node; tags may be a dict or the AIL `Tags` mapping.

**Return type**
Any

**Parameters**

- **name** (*str*)
- **default** (*Any*)

angr.go.codegen_builtins_values.**render_builtin_call_value**(*call*)

Chunks for `call` (a GoFunctionCall) when it needs special rendering, None otherwise.

**Return type**
Iterator | None

### 10.21.4 angr.go.knowledge_plugins

**class** angr.go.knowledge_plugins.**GoGlobals**

Bases: *KnowledgeBasePlugin*

Package-level variables recovered without data symbols: the runtime's own globals located by shape (*angr.go.analyses.runtime_globals*) and the variables typed from their initializers (*angr.go.analyses.package_variables*). Computed once per project by *angr.go.analyses.go_globals_recovery.GoGlobalsRecovery*, lazily on first use unless it was run ahead of time; `kb.go_signatures.variable_at` consults it after the symbol-backed sources.

**__init__**(*kb*)

**load**()

Run `GoGlobalsRecovery` once; later calls are no-ops.

**Return type**
None

**mark_loaded**()

**Return type**
None

**property loaded:** bool

**property variables:** dict[int, *GoVariable*]

**note**(*var*, *replace=False*)

Record a variable; an address already known keeps its first record unless `replace`.

**Return type**
None

**Parameters**

- **var** (GoVariable)
- **replace** (*bool*)

**variable_at**(*addr*)

**Return type**
*GoVariable* | None

**Parameters**
**addr** (*int*)

**addr_of**(*name*)

**Return type**
int | None

**Parameters**
**name** (*str*)

**copy**()

**class** angr.go.knowledge_plugins.**GoSignatures**

Bases: *KnowledgeBasePlugin*

Go function signatures and named types known for this binary, merged from every source (external tools, DWARF, the binary's runtime type descriptors, the stdlib database, in that priority) and turned into Go SimTypes on demand.

**__init__**(*kb*)

**record_version**(*key*)

The counter value when the record `key` (a function name, `callsite:0x..` or `closure:0x..`) last changed; 0 when it was never written.

**Return type**
int

**Parameters**
**key** (*str*)

**record_fingerprint**(*key*)

A process-independent spelling of the record `key` as it is now (None when absent), for comparing what a decompilation consulted with what another process knows.

**Return type**
str | None

**Parameters**
**key** (*str*)

**track**()

Record which inference records are consulted while the block runs, each with the version it had when first consulted (`deps`). Nested scopes report to the enclosing one.

**Return type**
Iterator[dict[str, int]]

`untracked`()

Suspend dependency tracking: for one-off whole-binary scans that are nobody's dependency.

**Return type**
Iterator[None]

`note`(*name*)

Count the inferred record of `name` as consulted by the decompilation in progress.

**Return type**
None

**Parameters**
**name** (*str*)

`deps_current`(*deps*, *version*)

Whether a decompilation that started from `version` and consulted `deps` (key -> version seen) reflects the current records: none of them changed since. Without a dependency list only the global counter decides.

**Return type**
bool

**Parameters**

- **deps** (*dict[str, int] | None*)
- **version** (*int | None*)

`is_current`(*cache*)

Whether the decompilation in `cache` (a DecompilationCache) reflects the current inference records.

**Return type**
bool

`stale_decompilations`(*kb=None*)

The `(addr, flavor)` keys of the Go decompilations in `kb.decompilations` that are out of date.

**Return type**
list[tuple[int, str]]

`add_source`(*sigs*, *priority=None*)

Register a signature set; earlier sources win. `priority=0` puts it in front.

**Return type**
None

**Parameters**

- **sigs** (GoSignatureSet)
- **priority** (*int | None*)

`load_sources`(*go_version=None*)

Load the binary's own DWARF signatures (when present), its runtime type descriptors and the stdlib database for its Go version. Runs once.

**Return type**
bool

**Parameters**
**go_version** (*str | None*)

**load_stdlib**(*go_version=None*)

Load the binary's own DWARF signatures (when present), its runtime type descriptors and the stdlib database for its Go version. Runs once.

**Return type**
bool

**Parameters**
**go_version** (*str | None*)

**signature**(*name*)

**Return type**
*GoFuncSignature* | None

**Parameters**
**name** (*str*)

**variable_at**(*addr*)

**Return type**
*GoVariable* | None

**Parameters**
**addr** (*int*)

**named_type**(*name*)

**Return type**
*GoNamedType* | None

**Parameters**
**name** (*str*)

**type_name_at**(*addr*)

The name of the type whose runtime descriptor is at `addr`, when a source (DWARF) recorded it.

**Return type**
str | None

**Parameters**
**addr** (*int*)

**property parser:** *GoTypeParser*

**type**(*type_str*)

**Return type**
*SimType*

**Parameters**
**type_str** (*str*)

**prototype**(*name*)

The function type of `name` (receiver first), or None when the signature is unknown.

**Return type**
*GoSimTypeFunction* | None

**Parameters**
**name** (*str*)

**set_inferred**(*name*, *param_types=None*, *results=None*, *caller_results=None*, *result_words=0*, *groups=None*, *return_words=0*, *fp_results=None*)

Record what was inferred for `name` (kept until a real signature appears): parameter types, callee-side result types, caller-side result types and word groups, how many result registers its returns write, or a whole record (as `inferred_record` returns it, possibly after a round trip through JSON) in place of the parameter types.

**Return type**
*GoInferredSignature*

**Parameters**

- **name** (*str*)
- **param_types** (*list[str] | dict | None*)
- **results** (*dict[int, tuple[str, int]] | None*)
- **caller_results** (*dict[int, tuple[str, int]] | None*)
- **result_words** (*int*)
- **groups** (*dict[int, tuple[int, str | None]] | None*)
- **return_words** (*int*)
- **fp_results** (*dict[int, str] | None*)

**set_callsite_inferred**(*addr*, *caller_results=None*, *result_words=0*, *groups=None*, *fp_results=None*)

Record what the caller's reads say about the results of the indirect call at `addr` (an interface method or closure without a known signature); the next decompilation types the call-site prototype from it.

**Return type**
*GoInferredSignature*

**Parameters**

- **addr** (*int*)
- **caller_results** (*dict[int, tuple[str, int]] | None*)
- **result_words** (*int*)
- **groups** (*dict[int, tuple[int, str | None]] | None*)
- **fp_results** (*dict[int, str] | None*)

**callsite_record**(*addr*)

**Return type**
*GoInferredSignature* | None

**Parameters**
**addr** (*int*)

**inferred**(*name*)

The inferred parameter types of `name`.

**Return type**
list[str] | None

**Parameters**
**name** (*str*)

inferred_record(*name*)

**Return type**
*GoInferredSignature* | None

**Parameters**
**name** (*str*)

results_guessed(*func*)

True when nothing but the calling-convention guess describes the results of `func`: its prototype is guessed, or it was rebuilt (a promoted receiver, inferred parameters) around the guessed result type.

**Return type**
bool

**Parameters**
**func** (Function)

fp_results_open(*func*)

True when callers may still add floating-point results to `func`: no real signature and no user prototype describe it. Its integer results may already be typed (inferred), which says nothing about the float ones.

**Return type**
bool

**Parameters**
**func** (Function)

untyped_params(*func*)

Indices of the parameters of `func` that only the calling-convention guess describes: a prototype rebuilt around a promoted receiver or inferred results keeps the guessed words (non-Go types, or the `uintptr` an inferred record spells for words it could not type). Type inference may know better about those, so they are no ground truth. Parameters of a real signature always are.

**Return type**
frozenset[int]

**Parameters**
**func** (Function)

inferred_prototype(*name*, *guessed*)

The inferred signature of `name` as a function type: inferred parameter types (else the guessed ones) and inferred result types (else the guessed result type `guessed.returnty`).

**Return type**
*GoSimTypeFunction* | None

**Parameters**
**name** (*str*)

set_closure_context(*addr*, *type_str*)

Record the closure record type a parent function builds for the closure body at `addr`.

**Return type**
None

**Parameters**

- **addr** (*int*)
- **type_str** (*str*)

**closure_context**(*addr*)

The closure record type of the body at `addr` (captures are its fields after `F`), if known.

**Return type**
str | None

**Parameters**
**addr** (*int*)

**arg_size_at**(*addr*)

The byte size of the parameters of the function at `addr` from the pclntab (results excluded).

**Return type**
int | None

**Parameters**
**addr** (*int*)

**prototype_at**(*addr*)

The function type of the method whose code starts at `addr`, from the runtime type descriptors' method tables (receiver first). Covers methods of named types in stripped binaries, which no signature source names.

**Return type**
*GoSimTypeFunction* | None

**Parameters**
**addr** (*int*)

**copy**()

**class** angr.go.knowledge_plugins.**GoTypes**

Bases: *KnowledgeBasePlugin*

The runtime type descriptors of this binary (*angr.go.analyses.type_descriptors*), parsed once on first use: descriptor address <-> canonical Go type string, itabs, and the named-type records that back `kb.go_signatures`.

**__init__**(*kb*)

**property descriptors:** *GoTypeDescriptors*

**property loaded:** bool

**property go_version:** str | None

**property types:** *GoSignatureSet*

**name_at**(*addr*)

The canonical Go type string of the descriptor at `addr`.

**Return type**
str | None

**Parameters**
**addr** (*int*)

**addr_of**(*name*)

The descriptor address of the type spelled `name`.

**Return type**
int | None

**Parameters**
**name** (*str*)

`itab_at`(*addr*)

`(interface type, concrete type)` of the itab at `addr`.

**Return type**
tuple[str, str] | None

**Parameters**
**addr** (*int*)

`method_at`(*addr*)

`(receiver type, method name, func type)` of the method whose code starts at `addr`.

**Return type**
tuple[str, str, str] | None

**Parameters**
**addr** (*int*)

`type_at`(*addr*)

The SimType of the descriptor at `addr`, built by `kb.go_signatures`.

**Return type**
*SimType* | None

**Parameters**
**addr** (*int*)

`copy`()

## Submodules

### angr.go.knowledge_plugins.go_globals

**class** angr.go.knowledge_plugins.go_globals.**GoGlobals**

Bases: *KnowledgeBasePlugin*

Package-level variables recovered without data symbols: the runtime's own globals located by shape (*angr.go.analyses.runtime_globals*) and the variables typed from their initializers (*angr.go.analyses.package_variables*). Computed once per project by *angr.go.analyses.go_globals_recovery.GoGlobalsRecovery*, lazily on first use unless it was run ahead of time; `kb.go_signatures.variable_at` consults it after the symbol-backed sources.

`__init__`(*kb*)

`load`()

Run `GoGlobalsRecovery` once; later calls are no-ops.

**Return type**
None

`mark_loaded`()

**Return type**
None

**property loaded: bool**

**property variables: dict[int, *GoVariable*]**

**note**(*var*, *replace=False*)

Record a variable; an address already known keeps its first record unless `replace`.

**Return type**
None

**Parameters**

- **var** (GoVariable)
- **replace** (*bool*)

**variable_at**(*addr*)

**Return type**
*GoVariable* | None

**Parameters**
**addr** (*int*)

**addr_of**(*name*)

**Return type**
int | None

**Parameters**
**name** (*str*)

**copy**()

### angr.go.knowledge_plugins.go_signatures

angr.go.knowledge_plugins.go_signatures.**placeholder_group**(*words*)

The spelling of `words` result words read together that nobody typed: a struct, so that it still travels in result registers (an array would go through memory under ABIInternal).

**Return type**
str

**Parameters**
**words** (*int*)

angr.go.knowledge_plugins.go_signatures.**is_placeholder_type**(*type_str*)

`uintptr` or a word group nobody typed (`struct { W0 uintptr; W1 uintptr }`, `[]uintptr`).

**Return type**
bool

**Parameters**
**type_str** (*str*)

**class** angr.go.knowledge_plugins.go_signatures.**GoInferredSignature**

Bases: dict

What the decompiler inferred about a function nobody names: parameter types from the callees its parameters reach, and result types from its own return statements (`results`, word -> (type, words spanned)) and from how

callers use the result registers (`caller_results`). `groups` (word -> (words spanned, type or None)) are caller-side groupings of result words read as one value, typed when the shape of the reads says what they are (an interface pair), else kept together as a placeholder. Word indices count ABIInternal integer result registers; `fp_results` (index -> type) counts the floating-point ones, which Go assigns independently. A plain dict underneath so records survive JSON and pickling between the processes of a sweep.

**property params:** `list[str] | None`

**property results:** `dict[int, tuple[str, int]]`

**property caller_results:** `dict[int, tuple[str, int]]`

**property groups:** `dict[int, tuple[int, str | None]]`

**property result_words:** `int`

How many result registers callers read after a call, typed or not.

**property return_words:** `int`

unknown).

**Type**
How many result registers the function's returns write, where that is fewer than the guess (0

**property fp_results:** `dict[int, str]`

**property has_int_results:** `bool`

**property has_results:** `bool`

**merge**(*params=None*, *results=None*, *caller_results=None*, *result_words=0*, *groups=None*, *return_words=0*, *fp_results=None*)

Parameter types replace the earlier ones; result types accumulate (over callers, and over passes as callees get typed), the first to type a word wins unless a later one types a wider value there. A typed group replaces an untyped one of the same span. The smallest `return_words` wins. Returns whether the record changed.

**Return type**
`bool`

**Parameters**

- **result_words** (*int*)
- **return_words** (*int*)

**fp_result_types**(*floor*)

The floating-point results, after the integer ones; `floor` is how many the guessed prototype has.

**Return type**
`list[str]`

**Parameters**
**floor** (*int*)

**result_types**(*floor*)

The result list: callee-side types win, caller-side types fill the gaps, then caller-side groups (an untyped group is spelled by `placeholder_group`), words nobody typed stay `uintptr`. `floor` is the number of words the guessed prototype already returns, less any its own returns showed it never writes.

**Return type**
`list[str]`

**Parameters**
**floor** (*int*)

angr.go.knowledge_plugins.go_signatures.**available_signature_dbs**()

Installed stdlib signature databases, keyed by minor version (`go1.22`).

**Return type**
dict[str, Path]

angr.go.knowledge_plugins.go_signatures.**load_signature_db**(*go_version*)

The stdlib signature database for `go_version`, falling back to the closest installed minor version.

**Return type**
*GoSignatureSet* | None

**Parameters**
**go_version** (*str | None*)

**class** angr.go.knowledge_plugins.go_signatures.**GoSignatures**

Bases: *KnowledgeBasePlugin*

Go function signatures and named types known for this binary, merged from every source (external tools, DWARF, the binary's runtime type descriptors, the stdlib database, in that priority) and turned into Go SimTypes on demand.

**__init__**(*kb*)

**record_version**(*key*)

The counter value when the record `key` (a function name, `callsite:0x..` or `closure:0x..`) last changed; 0 when it was never written.

**Return type**
int

**Parameters**
**key** (*str*)

**record_fingerprint**(*key*)

A process-independent spelling of the record `key` as it is now (None when absent), for comparing what a decompilation consulted with what another process knows.

**Return type**
str | None

**Parameters**
**key** (*str*)

**track**()

Record which inference records are consulted while the block runs, each with the version it had when first consulted (`deps`). Nested scopes report to the enclosing one.

**Return type**
Iterator[dict[str, int]]

**untracked**()

Suspend dependency tracking: for one-off whole-binary scans that are nobody's dependency.

**Return type**
Iterator[None]

`note`(*name*)

Count the inferred record of `name` as consulted by the decompilation in progress.

**Return type**
None

**Parameters**
**name** (*str*)

`deps_current`(*deps*, *version*)

Whether a decompilation that started from `version` and consulted `deps` (key -> version seen) reflects the current records: none of them changed since. Without a dependency list only the global counter decides.

**Return type**
bool

**Parameters**

- **deps** (*dict[str, int] | None*)
- **version** (*int | None*)

`is_current`(*cache*)

Whether the decompilation in `cache` (a DecompilationCache) reflects the current inference records.

**Return type**
bool

`stale_decompilations`(*kb=None*)

The `(addr, flavor)` keys of the Go decompilations in `kb.decompilations` that are out of date.

**Return type**
list[tuple[int, str]]

`add_source`(*sigs*, *priority=None*)

Register a signature set; earlier sources win. `priority=0` puts it in front.

**Return type**
None

**Parameters**

- **sigs** (GoSignatureSet)
- **priority** (*int | None*)

`load_sources`(*go_version=None*)

Load the binary's own DWARF signatures (when present), its runtime type descriptors and the stdlib database for its Go version. Runs once.

**Return type**
bool

**Parameters**
**go_version** (*str | None*)

`load_stdlib`(*go_version=None*)

Load the binary's own DWARF signatures (when present), its runtime type descriptors and the stdlib database for its Go version. Runs once.

**Return type**
bool

**Parameters**
**go_version** (*str | None*)

**signature**(*name*)

**Return type**
*GoFuncSignature* | None

**Parameters**
**name** (*str*)

**variable_at**(*addr*)

**Return type**
*GoVariable* | None

**Parameters**
**addr** (*int*)

**named_type**(*name*)

**Return type**
*GoNamedType* | None

**Parameters**
**name** (*str*)

**type_name_at**(*addr*)

The name of the type whose runtime descriptor is at `addr`, when a source (DWARF) recorded it.

**Return type**
str | None

**Parameters**
**addr** (*int*)

**property parser:** *GoTypeParser*

**type**(*type_str*)

**Return type**
*SimType*

**Parameters**
**type_str** (*str*)

**prototype**(*name*)

The function type of `name` (receiver first), or None when the signature is unknown.

**Return type**
*GoSimTypeFunction* | None

**Parameters**
**name** (*str*)

**set_inferred**(*name*, *param_types=None*, *results=None*, *caller_results=None*, *result_words=0*, *groups=None*, *return_words=0*, *fp_results=None*)

Record what was inferred for `name` (kept until a real signature appears): parameter types, callee-side result types, caller-side result types and word groups, how many result registers its returns write, or a whole record (as `inferred_record` returns it, possibly after a round trip through JSON) in place of the parameter types.

**Return type**
*GoInferredSignature*

**Parameters**

- **name** (*str*)
- **param_types** (*list[str] | dict | None*)
- **results** (*dict[int, tuple[str, int]] | None*)
- **caller_results** (*dict[int, tuple[str, int]] | None*)
- **result_words** (*int*)
- **groups** (*dict[int, tuple[int, str | None]] | None*)
- **return_words** (*int*)
- **fp_results** (*dict[int, str] | None*)

**set_callsite_inferred**(*addr*, *caller_results=None*, *result_words=0*, *groups=None*, *fp_results=None*)

Record what the caller's reads say about the results of the indirect call at `addr` (an interface method or closure without a known signature); the next decompilation types the call-site prototype from it.

**Return type**
*GoInferredSignature*

**Parameters**

- **addr** (*int*)
- **caller_results** (*dict[int, tuple[str, int]] | None*)
- **result_words** (*int*)
- **groups** (*dict[int, tuple[int, str | None]] | None*)
- **fp_results** (*dict[int, str] | None*)

**callsite_record**(*addr*)

**Return type**
*GoInferredSignature* | None

**Parameters**
**addr** (*int*)

**inferred**(*name*)

The inferred parameter types of `name`.

**Return type**
list[str] | None

**Parameters**
**name** (*str*)

**inferred_record**(*name*)

**Return type**
*GoInferredSignature* | None

**Parameters**
**name** (*str*)

**results_guessed**(*func*)

True when nothing but the calling-convention guess describes the results of `func`: its prototype is guessed, or it was rebuilt (a promoted receiver, inferred parameters) around the guessed result type.

**Return type**
bool

**Parameters**
**func** (Function)

**fp_results_open**(*func*)

True when callers may still add floating-point results to func: no real signature and no user prototype describe it. Its integer results may already be typed (inferred), which says nothing about the float ones.

**Return type**
bool

**Parameters**
**func** (Function)

**untyped_params**(*func*)

Indices of the parameters of func that only the calling-convention guess describes: a prototype rebuilt around a promoted receiver or inferred results keeps the guessed words (non-Go types, or the uintptr an inferred record spells for words it could not type). Type inference may know better about those, so they are no ground truth. Parameters of a real signature always are.

**Return type**
frozenset[int]

**Parameters**
**func** (Function)

**inferred_prototype**(*name*, *guessed*)

The inferred signature of name as a function type: inferred parameter types (else the guessed ones) and inferred result types (else the guessed result type guessed.returnty).

**Return type**
*GoSimTypeFunction* | None

**Parameters**
**name** (*str*)

**set_closure_context**(*addr*, *type_str*)

Record the closure record type a parent function builds for the closure body at addr.

**Return type**
None

**Parameters**

- **addr** (*int*)
- **type_str** (*str*)

**closure_context**(*addr*)

The closure record type of the body at addr (captures are its fields after F), if known.

**Return type**
str | None

**Parameters**
**addr** (*int*)

**arg_size_at**(*addr*)

The byte size of the parameters of the function at addr from the pclntab (results excluded).

**Return type**
int | None

**Parameters**
**addr** (*int*)

**prototype_at**(*addr*)

The function type of the method whose code starts at addr, from the runtime type descriptors' method tables (receiver first). Covers methods of named types in stripped binaries, which no signature source names.

**Return type**
*GoSimTypeFunction* | None

**Parameters**
**addr** (*int*)

**copy**()

### angr.go.knowledge_plugins.go_types

**class** angr.go.knowledge_plugins.go_types.**GoTypes**

Bases: *KnowledgeBasePlugin*

The runtime type descriptors of this binary (*angr.go.analyses.type_descriptors*), parsed once on first use: descriptor address <-> canonical Go type string, itabs, and the named-type records that back kb.go_signatures.

**__init__**(*kb*)

**property descriptors:** *GoTypeDescriptors*

**property loaded:** bool

**property go_version:** str | None

**property types:** *GoSignatureSet*

**name_at**(*addr*)

The canonical Go type string of the descriptor at addr.

**Return type**
str | None

**Parameters**
**addr** (*int*)

**addr_of**(*name*)

The descriptor address of the type spelled name.

**Return type**
int | None

**Parameters**
**name** (*str*)

**itab_at**(*addr*)

(interface type, concrete type) of the itab at addr.

**Return type**
tuple[str, str] | None

**Parameters**
**addr** (*int*)

`method_at`(*addr*)

`(receiver type, method name, func type)` of the method whose code starts at `addr`.

**Return type**
`tuple`[`str`, `str`, `str`] | `None`

**Parameters**
**addr** (*int*)

`type_at`(*addr*)

The SimType of the descriptor at `addr`, built by `kb.go_signatures`.

**Return type**
*SimType* | `None`

**Parameters**
**addr** (*int*)

`copy`()

### angr.go.optimization_passes.arg_spill_remover

**class** angr.go.optimization_passes.arg_spill_remover.**GoArgSpillRemover**

Bases: *OptimizationPass*

Drop stores into the incoming-argument spill area that the function never reads back, and unread prologue saves of the link register and the frame pointer (arm64 stores x30 and x29 into its own frame).

Under Go's register ABI the caller reserves a spill slot per register argument in its own frame, and the callee spills into those slots whenever it needs them (the morestack path, or every argument in unoptimized code). The slots sit above the return address, so the generic dead-store removal treats them as caller memory and keeps the stores. Nothing but this function ever reads them.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Remove unread Go argument spills'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.go.optimization_passes.atomic_rewriter

Fold the atomic instruction sequences the Go compiler emits back into the `sync/atomic` calls they came from.

On arm64 below GOARM64=v8.1 every atomic intrinsic is a dispatch on `runtime.arm64HasATOMICS` between an LSE instruction and an LL/SC retry loop. libVEX lifts the LSE instruction as an alignment-fault exit, fences and a compare-and-swap with a retry exit, all of which the structurer keeps as gotos. This pass drops the LL/SC arm, folds the LSE sequence into one call and strips the fault exits and fences from atomic loads and stores. On x86 the `lock xadd`, `xchg` and `lock cmpxchg` forms lift to the same compare-and-swap shape without the dispatch.

**class** angr.go.optimization_passes.atomic_rewriter.**GoAtomicRewriter**

Bases: *OptimizationPass*, *CFGTransformationMixin*

See the module docstring. Runs on the raw AIL, where the lifted shape of every instruction is exact.

**ARCHES = ['AARCH64', 'AMD64', 'X86']**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 1**

**NAME = 'Fold atomic instruction sequences into sync/atomic calls'**

**__init__**(*func*, *manager*, ***kwargs*)

**class** angr.go.optimization_passes.atomic_rewriter.**GoAtomicCasFolder**

Bases: *OptimizationPass*

Turn `atomic_compare_exchange(p, old, new) == old` into `atomic.CompareAndSwap*(p, old, new)` once the comparison is explicit, and give every synthesized atomic call its prototype.

ARCHES = ['AARCH64', 'AMD64', 'X86']

PLATFORMS = None

STAGE: *OptimizationPassStage* = 7

NAME = 'Fold compare-and-swap results into their bool'

__init__(*func*, *manager*, ***kwargs*)

static cas_bool(*call*)

**Return type**
*Call*

**Parameters**
**call** (Call)

set_prototype(*call*)

**Return type**
None

**Parameters**
**call** (Call)

### angr.go.optimization_passes.boxing_rewriter

class angr.go.optimization_passes.boxing_rewriter.**GoBoxingRewriter**

Bases: *OptimizationPass*, *CFGTransformationMixin*

Recover the values behind interface conversions and type assertions.

A value converted to an interface is a (type descriptor or itab, data pointer) pair. Passed directly, the pair is already fused into an interface-typed struct literal; the literal becomes `box(x)` tagged with the dynamic type. A variadic `...any` argument is a stack array of such pairs referenced through a `[]any` header; its element stores are folded into one `[]any{...}` literal and dropped.

A panicking assertion `x.(T)` is `if x.tab != T { panicdottype*() }` followed by reads of `x.data`; the sink and the branch are dropped and the data reads become the assertion.

ARCHES = None

PLATFORMS = None

STAGE: *OptimizationPassStage* = 7

NAME = 'Recover boxed values behind interface conversions'

__init__(*func*, *manager*, ***kwargs*)

rewrite_struct(*expr*, *block*, *stmt*)

**Return type**
*Expression* | None

**Parameters**

- **expr** (Struct)
- **block** (*Block*)
- **stmt** (Statement)

**fuse_pairs**(*exprs*, *stmt*)

Adjacent (type descriptor or itab, data word) words in an argument or result list are one interface value: the register pair of a boxed value passed to a callee without a Go prototype, or returned.

**Return type**
list

**Parameters**

- **exprs** (*list*)
- **stmt** (Statement)

### angr.go.optimization_passes.builtin_rewriter

**class** angr.go.optimization_passes.builtin_rewriter.**GoBuiltinRewriter**

Bases: *OptimizationPass*, *CFGTransformationMixin*

Turn calls into the Go runtime back into the builtins and operators the compiler lowered them from: `new`, `make`, `append`, `copy`, `panic`, string concatenation/comparison and the string/slice conversions.

`growslice` is special: the compiler only calls it when the slice must grow, so the call sits under an `if newLen > cap` diamond whose join block stores the appended elements (go1.25+ nests a stack-buffer choice under the check). The diamond is folded into one unconditional `append(s, elems...)` (append grows on demand itself) and the element stores are dropped; a `memmove`/`typedslicecopy` of the new elements is `append(s, t...)`. The slice may be a tracked value, a field of a struct in memory, a header the compiler keeps in three scalars, or an array (`arr[:n]`). When the elements cannot be matched the call still becomes `append(s)` with a comment giving the element count.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Rewrite Go runtime calls into builtins'**

**values: _Values**

**__init__**(*func*, *manager*, ***kwargs*)

**static block_use_counts**(*block*)

**Return type**
Counter

**Parameters**
**block** (*Block*)

**callee_name**(*call*)

**Return type**
str | None

**Parameters**
**call** (Call)

**type_name**(*expr*)

**Return type**
str | None

**Parameters**
**expr** (Expression)

`type_size`(*expr*)

**Return type**
int | None

**Parameters**
**expr** (Expression)

`builtin`(*call*, *name*, *args*, *bits=None*, *arg_types=None*, ***extra*)

**Return type**
*Call*

**Parameters**

- **call** (Call)
- **name** (*str*)
- **args** (*list*)
- **bits** (*int | None*)
- **arg_types** (*list[str] | None*)

`length_facts`()

**Return type**
*LengthFacts*

`cond_targets`(*block*)

The (true, false) target blocks of the conditional jump ending `block`.

**Return type**
tuple[Block, Block] | None

**Parameters**
**block** (*Block*)

`string_length`(*facts*, *ptr*, *n*, *prefix=False*)

The length word that goes with the string bytes at `ptr` when the guards pin it to `n` (or, with `prefix`, bound it below by `n`), and whether it is pinned. The tracked string's own length when there is one; else the value of the nearest such guard.

**Return type**
tuple[*Expression*, bool] | None

**Parameters**

- **facts** (*list*)
- **ptr** (Expression)
- **n** (*int*)
- **prefix** (*bool*)

`string_value`(*ptr*, *length*)

The string with the given pointer and length words: the tracked value, else spelled field by field.

**Return type**
*Expression*

**Parameters**

- **ptr** (Expression)
- **length** (Expression)

**to_bits**(*expr*, *bits*)

**Return type**
*Expression*

**Parameters**

- **expr** (Expression)
- **bits** (*int | None*)

**compare**(*op*, *lhs*, *rhs*, *bits*, *tags*)

**Return type**
*Expression*

**Parameters**

- **op** (*str*)
- **lhs** (Expression)
- **rhs** (Expression)
- **bits** (*int | None*)

**rewrite_call**(*call*, *block=None*, *stmt=None*)

**Return type**
*Expression* | None

**Parameters**

- **call** (Call)
- **block** (*Block | None*)
- **stmt** (Statement *| None*)

**rewrite_call_stmt**(*stmt*)

**Return type**
*Statement* | None

**Parameters**
**stmt** (SideEffectStatement)

**rewrite_binop**(*expr*)

**Return type**
*Expression* | None

**Parameters**
**expr** (BinaryOp)

**rewrite_ite**(*expr*)

**Return type**
*Expression* | None

**Parameters**
**expr** (ITE)

`rewrite_struct`(*expr*)

**Return type**
*Expression* | None

**Parameters**
**expr** (Struct)

### angr.go.optimization_passes.check_remover

angr.go.optimization_passes.check_remover.**is_go_check_panic_name**(*name*)

**Return type**
bool

**Parameters**
**name** (*str | None*)

angr.go.optimization_passes.check_remover.**is_go_write_barrier_name**(*name*)

**Return type**
bool

**Parameters**
**name** (*str | None*)

**class** angr.go.optimization_passes.check_remover.**GoCheckRemover**

Bases: *OptimizationPass*, *CFGTransformationMixin*

Remove compiler-inserted checks whose failure path is a panic stub, and GC write-barrier slow paths.

A bounds/division check branches to a sink block that only spills the operands and calls a `runtime.panic*` helper; the block and the branch to it are dropped, so `s[i]` reads as an index expression again. A pointer store compiles to `if runtime.writeBarrier.enabled { gcWriteBarrierN(); buf[...] = ... }` followed by the real store on the join block; the barrier block only records the old and new pointers for the GC, so it and the branch are dropped as well.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 1**

**NAME = 'Remove Go bounds/division checks and write barriers'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.go.optimization_passes.closure_context

**class** angr.go.optimization_passes.closure_context.**GoClosureContextNamer**

Bases: *OptimizationPass*

Name the variable that stands for the incoming closure context register `ctx` (codegen prints it as the first parameter) and, when the parent's closure record is known, type it as `*struct { F uintptr; X0 T; ... }` so captures read as `ctx.X0`.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 8**

**NAME = 'Name the Go closure context register'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.go.optimization_passes.descriptor_namer

**class** angr.go.optimization_passes.descriptor_namer.**GoDescriptorNamer**

Bases: *OptimizationPass*

Name globals that are runtime type descriptors or itabs the way the linker does (`type:int`, `go:itab.*os.File,io.Writer`), so stripped binaries read like unstripped ones.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 8**

**NAME = 'Name Go type descriptor globals'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.go.optimization_passes.errors_folder

Fold the inlined parts of `fmt.Errorf` and `errors.New` back into calls.

Since CL 708836 (go1.27) `fmt.Errorf(format, a...)` is split so it inlines into its callers:

```
if err = errorf(format, a...); err != nil { return err }
return errors.New(format)      // &errorString{format}
```

The caller keeps the `errorf` call, a nil check of its itab word and a fallback arm that allocates an `errors.errorString` holding the format. The fallback is dropped and the call becomes `fmt.Errorf`. A remaining `new(errors.errorString)` whose string field is stored right away is an inlined `errors.New(s)`.

**class** angr.go.optimization_passes.errors_folder.**ErrorsFolder**

Bases: `object`

Run by `GoBuiltinRewriter` before its call rewriting (allocations are still runtime calls).

**__init__**(*pass_*)

**Parameters**
**pass_** (`GoBuiltinRewriter`)

**run**()

**Return type**
`bool`

### angr.go.optimization_passes.global_types

**class** angr.go.optimization_passes.global_types.**GoGlobalTypes**

Bases: *OptimizationPass*

Give package-level variables referenced by this function the types the signature sources (DWARF) know for them, and the runtime's itabs and type descriptors their struct types, pinned as manual types so type inference treats them as ground truth (an itab's Type word read through `go:itab.*T,I` is then `.Type`, not `field_8`).

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Pin Go package-level variable types'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.go.optimization_passes.header_word_types

**class** angr.go.optimization_passes.header_word_types.**GoHeaderWordTypes**

Bases: *OptimizationPass*

Keep the length and capacity words of string and slice headers integers. Type inference happily unifies a `len` word with the pointer word it travels next to and renders `(*int8)(n)` and `unsafe.Pointer` locals for what is an `int`. A variable is proven an integer when it is the `len`/`cap` leaf of a fused header (a call argument or a return value), when it is passed where a typed callee takes an integer, or when it is compared in order against the `len`/`cap` word of a header; those variables are pinned as ground truth for type inference.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Pin Go header length words to int'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.go.optimization_passes.multi_value

**class** angr.go.optimization_passes.multi_value.**GoRetExprRewriter**

Bases: *RetExprRewriter*

Give calls to functions with several results a combo-register return expression.

**NAME = 'Rewrite return expressions of calls to Go functions with several results'**

**FLAVOR = 'go'**

**class** angr.go.optimization_passes.multi_value.**GoComboRegisterRewriter**

Bases: *ComboRegisterRewriter*

Fold register pairs that make up one combo-register parameter back into that parameter.

**NAME = 'Rewrite combo-register parameter references'**

class angr.go.optimization_passes.multi_value.**GoCallResultBinder**

Bases: *OptimizationPass*

Bind every result register a caller reads after a call to the call's result when the callee's results are only guessed (or the callee is unknown: interface methods, closures). ABIInternal clobbers all result registers at a call, so a read of rbx/x1 before any write after the call is the call's second result; the same holds for the float result registers (xmm0, xmm1, …), which Go numbers independently. Direct callees learn the word count (and `bool` for words only read as a byte) through `kb.go_signatures`; indirect calls get a combo-register result and a call-site prototype.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 1**

**NAME = 'Bind the result registers callers read after Go calls'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.go.optimization_passes.parameter_types

class angr.go.optimization_passes.parameter_types.**GoParameterTypes**

Bases: *OptimizationPass*

Pin the types of parameter variables to the function's Go prototype so type inference treats them as ground truth instead of re-deriving (and often flattening) string/slice/struct parameters from their uses.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Pin Go parameter types'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.go.optimization_passes.pinned_register_namer

class angr.go.optimization_passes.pinned_register_namer.**GoPinnedRegisterNamer**

Bases: *OptimizationPass*

Name the variable that stands for the g register `g` and type it `*runtime.g`.

The register is never written by compiled Go code, so variable recovery sees an undefined input and names it like any other; the name and type make g.m / g.stackguard0 accesses readable.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 8**

**NAME = 'Name the Go g register'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.go.optimization_passes.pinned_register_rewriter

**class** angr.go.optimization_passes.pinned_register_rewriter.**GoPinnedRegisterRewriter**

Bases: *OptimizationPass*

Fold reads of the ABI zero register (X15 on amd64) into the constant 0.

Compiled Go code never writes the zero register, so its reads are the constant 0 rather than an undefined input; leaving them alone turns every zero-initialization into a phantom parameter.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 1**

**NAME = 'Fold the Go zero register into constants'**

**__init__**(*func*, *manager*, ***kwargs*)

**class** angr.go.optimization_passes.pinned_register_rewriter.**GoWideZeroStoreSplitter**

Bases: *OptimizationPass*

`MOVUPS X15, off(SP)` zeroes two words of a frame slot at once. Split it into word stores so the words of a slice/string header kept in the frame stay separate stack variables instead of one 16-byte variable that every later word write updates with an insert.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 3**

**NAME = 'Split Go wide zero stores into words'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.go.optimization_passes.prototype_inference

**class** angr.go.optimization_passes.prototype_inference.**GoPrototypeInference**

Bases: *OptimizationPass*

Infer the signature of a function nobody names (no DWARF, not in the signature database, not a method) from the typed code around it:

- parameters, from how they reach callees whose prototypes are known: a parameter word passed where a callee takes an `int` is an int, two consecutive words fused into `io.Writer` for a callee are an `io.Writer`;
- results, from what its return statements put in the result registers (a `new(T)` gives `*T`, a constant string header a `string`, an itab an interface, a known callee's result its type) and from how callers use the result registers of calls to it (passed to a typed callee, returned through a typed prototype, stored into a typed field, compared against an itab).

Everything is recorded in `kb.go_signatures` as an inferred signature; it takes effect the next time the function is decompiled (the argument variables and return sites are built before any pass runs).

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Infer Go signatures from typed callers and callees'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.go.optimization_passes.prototypes

angr.go.optimization_passes.prototypes.**receiver_type_from_name**(*kb*, *arch*, *name*)

pkg.(*T).M -> the SimType of *pkg.T; pkg.T.M -> pkg.T when it is one word wide. T must be a type the binary describes. Closures (.func1) and plain functions give None.

**Parameters**
**name** (*str*)

**class** angr.go.optimization_passes.prototypes.**GoPrototypes**

Bases: *OptimizationPass*

Give the current function and its callees their Go prototypes (from DWARF, the stdlib signature database or an external source registered on kb.go_signatures) before return sites, argument lists and call sites are built.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 0**

**NAME = 'Apply known Go prototypes'**

**__init__**(*func*, *manager*, ***kwargs*)

**class** angr.go.optimization_passes.prototypes.**GoPrototypeApplier**

Bases: object

Puts the best known Go prototype of a function on it: a signature, an inferred one, or the bounded guess.

**__init__**(*project*, *kb*)

**apply**(*func*)

**Return type**
bool

**Parameters**
**func** (Function)

### angr.go.optimization_passes.result_widener

**class** angr.go.optimization_passes.result_widener.**GoResultWidener**

Bases: *OptimizationPass*

Let the return statements of a function whose results are only guessed name every ABIInternal result register that holds a value at the return: registers written on all paths since the last call, or carried by that call's results. The calling-convention guess only ever counts the first two, so the result inference would otherwise never see the cap word of a slice or the error behind a pointer. The prototype keeps its guessed shape; the extra expressions are tagged with the guessed word count and dropped again once the inference has read them.

A guess can also count too many: a result register a callee left behind looks returned. When a return site of known provenance leaves it unset and the function never writes it after its last call, it is dropped from the returns and from the guessed prototype.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 1**

**NAME = 'Widen guessed Go return statements to every result register'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.go.optimization_passes.runtime_rewriter

Turn calls into the Go runtime for maps, channels, goroutines, defer and panic/recover back into the Go statements they were compiled from. See *angr.go.codegen_builtins* for the `go_render` tag protocol the results use.

angr.go.optimization_passes.runtime_rewriter.**classify_runtime_call**(*name*)

**Return type**
str | None

**Parameters**
**name** (*str | None*)

**class** angr.go.optimization_passes.runtime_rewriter.**GoRuntimeRewriter**

Bases: *OptimizationPass*

Rewrite Go runtime calls into map, channel, goroutine, defer and panic/recover statements.

Map slot pointers returned by `mapaccess1`/`mapassign` are folded into the loads and the store that go through them (`m[k]`, `m[k] = v`); results the runtime writes through a stack pointer (`chanrecv`) become the value of the rewritten call; open-coded defers (a deferBits byte plus an inline call at every exit) become `defer`.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Rewrite Go runtime calls into Go statements'**

**__init__**(*func*, *manager*, ***kwargs*)

**nested_makemap**(*call*)

`make(map[K]V[, hint])` for a makemap call that is not the source of a definition.

**Return type**
*Call* | None

**Parameters**
**call** (*Call*)

**index_call**(*m*, *k*, *bits*, *tags*)

**Return type**
*Call*

**Parameters**

- **m** (*Expression*)
- **k** (*Expression*)
- **bits** (*int*)
- **tags** (*dict*)

**assign_call**(*m*, *k*, *v*, *tags*)

**Return type**
*Call*

**Parameters**

- **m** (Expression)
- **k** (Expression)
- **v** (Expression)
- **tags** (*dict*)

**func_value_call**(*call*)

`(*f)(args...)` through a func value becomes `f(args...)` with the signature's arity.

**Return type**
*Call* | None

**Parameters**
**call** (Call)

### angr.go.optimization_passes.stack_check_remover

**class** angr.go.optimization_passes.stack_check_remover.**GoStackCheckRemover**

Bases: *OptimizationPass*, *CFGTransformationMixin*

Remove the goroutine stack-growth check every Go function starts with.

The check compares the stack pointer against g.stackguard0 and, when the frame does not fit, branches to a trampoline that spills the register arguments, calls runtime.morestack, reloads the arguments and jumps back to the function entry. Neither the compare, the spills nor the restart mean anything at the source level, so the trampoline is dropped and the branch leading to it becomes a plain jump; the now-dead compare is cleaned up by later stages. runtime.morestackc (//go:systemstack functions) does not return, so its trampoline ends at the call.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 1**

**NAME = 'Remove the goroutine stack-growth check'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.go.optimization_passes.stack_inits

Stack initializations the compiler expands inline.

`make(map[K]V)` of a map that does not escape (go1.24+ swiss maps): the compiler places the `maps.Map` header and one group on the stack, zeroes both, marks the group's control word empty, points `dirPtr` at the group and seeds the hash with `runtime.rand()`. The whole sequence becomes `m := make(map[K]V)` and `&header` becomes `m`.

Large zero values are cleared by a loop over the variable (plus stores for the tail); that is one `memset`.

**class** angr.go.optimization_passes.stack_inits.**SmallMapFolder**

Bases: _StackScan

See the module docstring.

**run**()

**Return type**
list[Block]

**class** angr.go.optimization_passes.stack_inits.**StackClearFolder**

Bases: _StackScan

A loop clearing a stack variable `stride` bytes per trip, plus the stores clearing its tail, is one `memset(&v, 0, size)`; the code generator spells a whole-variable clear as `v = T{}`.

**run**()

**Return type**
bool

**class** angr.go.optimization_passes.stack_inits.**GoSmallMapFolder**

Bases: *OptimizationPass*, *CFGTransformationMixin*

`make(map[K]V)` of a non-escaping map, inlined onto the stack (see the module docstring). Runs before the map accesses are rewritten, while their type descriptors still name the map type.

**ARCHES** = None

**PLATFORMS** = None

**STAGE**: *OptimizationPassStage* = 7

**NAME** = 'Fold Go stack-allocated map initializations'

**__init__**(*func*, *manager*, ***kwargs*)

**callee_name**(*call*)

**Return type**
str | None

**Parameters**
**call** (Call)

### angr.go.optimization_passes.stdlib_folder

**class** angr.go.optimization_passes.stdlib_folder.**GoStdlibFolder**

Bases: *OptimizationPass*, *CFGTransformationMixin*

Fold inlined standard-library bodies back into the calls they came from.

container/list: `new(List)` plus the `Init` stores is `list.New()`; `lazyInit` (`if l.root.next == nil { l.Init() }`) followed by `new(Element)` and the `insert` stores is `l.PushBack(v)`/`l.PushFront(v)`; `l.len == 0 ? nil : l.root.next` is `l.Front()` (`root.prev`: `Back()`). A fold needs the whole body.

**ARCHES** = None

**PLATFORMS** = None

**STAGE**: *OptimizationPassStage* = 7

**NAME** = 'Fold inlined Go standard-library functions'

**__init__**(*func*, *manager*, ***kwargs*)

**rewrite_ite**(*expr*)

`l.len == 0 ? nil : l.root.next -> l.Front()` (`root.prev: l.Back()`).

**Return type**
*Expression* | None

**Parameters**
**expr** (ITE)

### angr.go.optimization_passes.string_compares

String comparisons the Go compiler lowers to a length check plus little-endian word compares of the bytes.

**class** angr.go.optimization_passes.string_compares.**LengthFacts**

Bases: object

What the dominating branches say about integer values (string lengths) at a block.

**__init__**(*rewriter*)

**Parameters**
**rewriter** (GoBuiltinRewriter)

**at**(*block*)

(value, interval) pairs, nearest guard first.

**Return type**
list[tuple[*Expression*, _Interval]]

**Parameters**
**block** (Block)

**class** angr.go.optimization_passes.string_compares.**StringCompareFolder**

Bases: object

`len(s) == n` dominating a chain of word compares `*(*uintK)(s.ptr + k) == c` that together cover the n bytes of a printable string and all fail to the same place: the first compare becomes `s == "..."` and the rest become jumps. When the length check itself leads to the chain and fails to the same place, it becomes the string compare instead. "The same place" looks through jump-only blocks and constant branches.

**__init__**(*rewriter*, *facts*)

**Parameters**

- **rewriter** (GoBuiltinRewriter)
- **facts** (LengthFacts)

**fold**()

**Return type**
int

**class** angr.go.optimization_passes.string_compares.**StringSwitchFlattener**

Bases: object

A string switch dispatches on the length and on single bytes before comparing whole strings. Once those compares are `s == "..."`, the dispatch only routes each literal to its own compare: it becomes a chain of the compares in address order, so the cases structure as one if/else-if chain over `s`.

__init__(*rewriter*)

**Parameters**
**rewriter** (GoBuiltinRewriter)

flatten()

**Return type**
int

### angr.go.optimization_passes.type_switch_simplifier

class angr.go.optimization_passes.type_switch_simplifier.**GoTypeSwitchSimplifier**

Bases: *OptimizationPass*, *CFGTransformationMixin*

Strip the search machinery the compiler puts in front of a type switch.

Concrete cases are found through a binary search over `t.Hash` whose leaves compare `t` against the case's type descriptor; the hash tests are redundant with those comparisons, so the tree collapses into a chain of descriptor comparisons. Interface cases (go1.22+) first probe an inline cache before calling `runtime.interfaceSwitch`; the probe loop is dropped and the call always runs. Assertions and conversions to interface types probe the same kind of cache ahead of `runtime.typeAssert`.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Simplify Go type switches'**

__init__(*func*, *manager*, ***kwargs*)

### angr.go.optimization_passes.value_fuser

class angr.go.optimization_passes.value_fuser.**GoValueFuser**

Bases: *OptimizationPass*

Re-assemble string, slice, interface and multi-result values that the ABI splits across several registers.

Call arguments and return values are grouped by the callee's (or the function's) Go prototype. A group that is a contiguous slice of one combo-register value becomes a load from that value, contiguous loads become one wider load, a constant (pointer, length) pair in read-only memory becomes a string literal, and anything else becomes a `Struct` expression.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Fuse Go values split across registers'**

__init__(*func*, *manager*, ***kwargs*)

**callee_prototype**(*call*)

**Return type**
*GoSimTypeFunction* | None

**Parameters**
**call** (Call)

**fuse_args**(*call*, *proto*)

**Return type**
list | None

**Parameters**

- **call** (Call)
- **proto** (GoSimTypeFunction)

**fuse_results**(*ret_exprs*, *proto*)

**Return type**
list | None

**Parameters**

- **ret_exprs** (*list*)
- **proto** (GoSimTypeFunction)

**fuse**(*ty*, *leaves*)

Turn the leaf expressions making up one value of type `ty` into a single expression.

**Parameters**

- **ty** (SimType)
- **leaves** (*list*)

### 10.21.6 angr.go.runtime_types

angr.go.runtime_types.**go_g_struct**(*arch*)

The leading fields of runtime.g. Only the version-stable prefix is described.

**Return type**
*SimStruct*

### 10.21.7 angr.go.signature

Language-level Go function signatures and named-type descriptions.

Every source of Go type information (the stdlib signature database, DWARF, runtime type descriptors, external tools) is normalized into these records before it is turned into SimTypes. Types are carried as *Go type strings* in canonical Go syntax with package-path-qualified names, e.g.:

```
int  uint8  uintptr  bool  string  error  unsafe.Pointer
*net/http.Server  []byte  [4]int  map[string][]int  chan<- int  func(int, string) (int,␣
↪error)
struct { x int; y int }  interface { Error() string }  any
```

Rules: - Named types are qualified with the full import path (`net/http.Server`, `main.point`, `os.File`); a type from package `main` is `main.T`. Predeclared types (`int`, `string`, `error`, `any`) are bare.

- Struct field lists use `;` separators; anonymous (embedded) fields are written as their type.
- Function types never carry parameter names; only signatures do.

- Generic instantiations use the compiler's spelling, e.g. `slices.Index[[]int,int]`.

JSON form (used by the on-disk signature databases):

```
{
  "go_version": "go1.22.5",
  "goarch": "amd64",
  "functions": {
    "strconv.Atoi": {"params": [["s", "string"]], "results": [["~r0", "int"], ["~r1",
↪"error"]]},
    "os.(*File).Write": {"recv": ["f", "*os.File"], "params": [["b", "[]byte"]],
                         "results": [["n", "int"], ["err", "error"]]}
  },
  "types": {
    "os.File": {"kind": "struct", "size": 8, "align": 8, "fields": [["file", "*os.file",␣
↪0]]},
    "error": {"kind": "interface", "methods": [["Error", "func() string"]]},
    "time.Duration": {"kind": "named", "underlying": "int64", "size": 8, "align": 8}
  }
}
```

`kind` is one of `struct`, `interface` and `named` (any other named type; `underlying` is its Go type string). Sizes and offsets are in bytes for `goarch`.

**class** angr.go.signature.**GoParam**

Bases: `object`

A named parameter or result and its canonical Go type string.

**name:** *str*

**type_str:** *str*

**__init__**(*name*, *type_str*)

**Parameters**

- **name** (*str*)
- **type_str** (*str*)

**Return type**
None

**class** angr.go.signature.**GoFuncSignature**

Bases: `object`

A Go function or method signature. `name` is the linker symbol name (`pkg.Func`, `pkg.(*T).Method`, `pkg.T.Method`, `pkg.Func.func1`).

**name:** *str*

**params:** *list[GoParam]*

**results:** *list[GoParam]*

**recv:** *GoParam* | *None*

property all_params: list[GoParam]

receiver first.

**Type**
Parameters in ABI order

to_json()

**Return type**
dict

classmethod from_json(*name*, *d*)

**Return type**
*GoFuncSignature*

**Parameters**

- **name** (*str*)
- **d** (*dict*)

__init__(*name*, *params=<factory>*, *results=<factory>*, *recv=None*)

**Parameters**

- **name** (*str*)
- **params** (*list[GoParam]*)
- **results** (*list[GoParam]*)
- **recv** (*GoParam | None*)

**Return type**
None

class angr.go.signature.GoStructField

Bases: object

A struct field: name, canonical Go type string and byte offset.

name: str

type_str: str

offset: int | None

__init__(*name*, *type_str*, *offset*)

**Parameters**

- **name** (*str*)
- **type_str** (*str*)
- **offset** (*int | None*)

**Return type**
None

class angr.go.signature.GoNamedType

Bases: object

A named Go type. `kind` is `struct` (`fields` set), `interface` (`methods` set) or `named` (`underlying` set).

**name:** str

**kind:** str

**size:** int | None

**align:** int | None

**fields:** list[*GoStructField*]

**methods:** list[tuple[str, str]]

**underlying:** str | None

**to_json**()

**Return type**
dict

**classmethod from_json**(*name*, *d*)

**Return type**
*GoNamedType*

**Parameters**

- **name** (*str*)
- **d** (*dict*)

**__init__**(*name*, *kind*, *size=None*, *align=None*, *fields=<factory>*, *methods=<factory>*, *underlying=None*)

**Parameters**

- **name** (*str*)
- **kind** (*str*)
- **size** (*int | None*)
- **align** (*int | None*)
- **fields** (*list[GoStructField]*)
- **methods** (*list[tuple[str, str]]*)
- **underlying** (*str | None*)

**Return type**
None

**class** angr.go.signature.**GoVariable**

Bases: object

A package-level variable: its linker symbol name, (rebased) address and Go type.

**name:** str

**addr:** int

**type_str:** str

__init__(*name*, *addr*, *type_str*)

**Parameters**

- **name** (*str*)
- **addr** (*int*)
- **type_str** (*str*)

**Return type**
None

class angr.go.signature.**GoSignatureSet**

Bases: object

A collection of signatures, named types and package-level variables from one source.

**go_version:** str | None

**goarch:** str | None

**functions:** dict[str, *GoFuncSignature*]

**types:** dict[str, *GoNamedType*]

**variables:** dict[str, *GoVariable*]

**runtime_types:** dict[int, str]

runtime type descriptor address -> type name (binary-specific, not serialized)

**to_json**()

**Return type**
dict

classmethod **from_json**(*d*)

**Return type**
*GoSignatureSet*

**Parameters**
**d** (*dict*)

**without_layout**(*goarch*)

The same set with sizes, alignments and field offsets dropped: they were computed for another GOARCH.

**Return type**
*GoSignatureSet*

**Parameters**
**goarch** (*str | None*)

__init__(*go_version=None*, *goarch=None*, *functions=<factory>*, *types=<factory>*, *variables=<factory>*, *runtime_types=<factory>*)

**Parameters**

- **go_version** (*str | None*)
- **goarch** (*str | None*)
- **functions** (*dict[str, GoFuncSignature]*)
- **types** (*dict[str, GoNamedType]*)

- **variables** (*dict[str, GoVariable]*)
- **runtime_types** (*dict[int, str]*)

**Return type**
None

### 10.21.8 angr.go.sim_type

Go-flavored SimTypes.

Every class carries an optional `go_name` (the declared name of a named type such as `time.Duration`), which is what gets rendered; the underlying representation decides size, layout and how values are passed.

**class** angr.go.sim_type.**GoSimType**

Bases: *SimType*

**go_name:** *str | None* = **None**

**go_repr**()

The canonical Go spelling of this type (its name when it is a named type).

**Return type**
str

**repr**(*name=None*, *full=0*, *memo=None*, *indent=0*)

**Parameters**
**indent** (*int | None*)

**c_repr**(*name=None*, *full=0*, *memo=None*, *indent=0*, *name_parens=True*, *show_void=True*, ***kwargs*)

**Parameters**

- **indent** (*int | None*)
- **name_parens** (*bool*)
- **show_void** (*bool*)

**class** angr.go.sim_type.**GoSimTypeInt**

Bases: *GoSimType*, *SimTypeInt*

An integer of explicit width. `go_name` distinguishes `int`/`uintptr`/`rune` from `int64`/`uint64`/ `int32`.

**property size:** *int*

The size of the type in bits, or None if no size is computable.

**property alignment**

The alignment of the type in bytes.

**copy**()

**Return type**
Self

**class** angr.go.sim_type.**GoSimTypeBool**

Bases: *GoSimTypeInt*

**copy**()

**Return type**
Self

class angr.go.sim_type.**GoSimTypeFloat**

Bases: *GoSimType*, *SimTypeFloat*

**property size: int**

The size of the type in bits, or None if no size is computable.

**property sort**

**copy**()

**Return type**
*GoSimTypeFloat*

class angr.go.sim_type.**GoSimTypePointer**

Bases: *GoSimType*, *SimTypePointer*

**property size**

The size of the type in bits, or None if no size is computable.

**copy**()

**Return type**
*GoSimTypePointer*

class angr.go.sim_type.**GoSimTypeUnsafePointer**

Bases: *GoSimTypePointer*

**copy**()

**Return type**
*GoSimTypeUnsafePointer*

class angr.go.sim_type.**GoSimTypeArray**

Bases: *GoSimType*, *SimTypeArray*

A fixed-size Go array `[N]T`.

**copy**()

**Return type**
*GoSimTypeArray*

class angr.go.sim_type.**GoSimStruct**

Bases: *GoSimType*, *SimStruct*

A Go struct. `go_name` is the qualified type name (`main.point`); anonymous structs have none. Field offsets and the total size may be pinned (`offsets`/`go_size`) when they come from a trusted source such as DWARF, so the layout never depends on angr's C-style alignment rules.

**go_size: int | None**

**property name: str**

**property offsets: dict[str, int]**

**property size**

The size of the type in bits, or None if no size is computable.

**property alignment**

The alignment of the type in bytes.

**go_definition_lines**()

Field lines of a `type X struct { ... }` definition.

**Return type**
list[str]

**copy**()

**Return type**
*GoSimStruct*

class angr.go.sim_type.**GoSimTypeString**

Bases: *GoSimStruct*

**property name:** str

class angr.go.sim_type.**GoSimTypeSlice**

Bases: *GoSimStruct*

**property name:** str

class angr.go.sim_type.**GoSimTypeInterface**

Bases: *GoSimStruct*

An interface value: an itab (or type) pointer and a data pointer. `methods` is a list of `(name, func_type)`; the empty method set is any.

**methods:** list[tuple[str, *SimType*]]

**property name:** str

**property is_empty:** bool

class angr.go.sim_type.**GoSimTypeTuple**

Bases: *GoSimStruct*

The result list of a function with more than one result, laid out like a struct.

**property name:** str

class angr.go.sim_type.**GoSimTypeMap**

Bases: *GoSimTypePointer*

**copy**()

**Return type**
*GoSimTypeMap*

class angr.go.sim_type.**GoSimTypeChan**

Bases: *GoSimTypePointer*

**copy**()

**Return type**
*GoSimTypeChan*

class angr.go.sim_type.**GoSimTypeFunction**

Bases: *GoSimType*, *SimTypeFunction*

A function signature: parameters (named) and results. More than one result is a `GoSimTypeTuple` return type so calling-convention code sees one struct-shaped value.

property results: list[*SimType*]

property result_names: list[str]

go_results_repr()

**Return type**
str

repr(*name=None*, *full=0*, *memo=None*, *indent=0*)

**Parameters**
**indent** (*int | None*)

copy()

**Return type**
*GoSimTypeFunction*

class angr.go.sim_type.**GoSimTypeFunc**

Bases: *GoSimTypePointer*

A func *value*: a pointer to a closure whose first word is the code pointer.

copy()

**Return type**
*GoSimTypeFunc*

angr.go.sim_type.**go_type_repr**(*ty*)

Spell any SimType the Go way; non-Go SimTypes get a best-effort mapping.

**Return type**
str

**Parameters**
**ty** (SimType | *None*)

angr.go.sim_type.**go_int**(*arch*, *size=None*, *signed=True*, *go_name=None*)

**Return type**
*GoSimTypeInt*

**Parameters**

- **size** (*int | None*)
- **signed** (*bool*)
- **go_name** (*str | None*)

### 10.21.9 angr.go.type_parser

Parse canonical Go type strings (see angr.go.signature) into Go SimTypes.

exception angr.go.type_parser.**GoTypeParseError**

Bases: ValueError

A malformed Go type string.

class angr.go.type_parser.**GoTypeParser**

Bases: object

Recursive-descent parser for Go type strings. `resolver` maps a qualified type name to its GoNamedType record (from a signature database or DWARF); unknown names become opaque structs.

**__init__**(*arch*, *resolver=None*)

**Parameters**
**resolver** (*Callable[[str], GoNamedType | None] | None*)

**parse**(*s*)

**Return type**
*SimType*

**Parameters**
**s** (*str*)

**parse_signature**(*params*, *results*, *arg_names=None*)

Build a function type from parameter and result type strings.

**Parameters**

- **params** (*list[str]*)
- **results** (*list[str]*)
- **arg_names** (*list[str] | None*)

**ITAB_NAMES** = ('internal/abi.ITab', 'runtime.itab')

**TYPE_NAMES** = ('internal/abi.Type', 'runtime._type')

**resolve_named**(*name*)

**Return type**
*SimType*

**Parameters**
**name** (*str*)

**itab_type**()

The runtime's itab struct as the binary describes it, or None.

**Return type**
*SimType* | None

**type_descriptor_type**()

The runtime's type descriptor struct as the binary describes it, or None.

**Return type**
*SimType* | None

## 10.21.10 angr.go.typehoon

### Submodules

*hints*
*translator*

continues on next page

Table 68 – continued from previous page

| *typehoon* |
|---|

### angr.go.typehoon.hints

angr.go.typehoon.hints.**collect_call_result_hints**(*project*, *graph*, *variable_map*, *type_lifter*)

Type hints for the results of calls with a Go signature: `v = f(...)` types `v` as the result type of `f`.

Type inference alone loses struct-shaped results (strings, slices, interfaces, tuples) held in register pairs to the default integer type of the same width, so the signature's word is made binding.

**Return type**
dict[int, *TypeConstant*]

angr.go.typehoon.hints.**closure_context_vvars**(*project*, *graph*)

The vvars that carry the closure context register into `function` (used, never defined).

**Return type**
list[int]

angr.go.typehoon.hints.**collect_closure_context_hints**(*project*, *function*, *graph*, *type_lifter*)

Type hints for the closure context register of a closure body whose parent recorded the closure record (`kb.go_signatures.closure_context`): the undefined context vvars are pointers to that record.

**Return type**
dict[int, *TypeConstant*]

### angr.go.typehoon.translator

**class** angr.go.typehoon.translator.**GoTypeTranslator**

Bases: *TypeTranslator*

Bidirectional translator between Go SimTypes and type constants.

**ctype2go**(*simtype*)

Re-express a C-flavored SimType with Go SimTypes.

**Return type**
*SimType*

**Parameters**
**simtype** (SimType)

**arch:** Arch

**func_addr:** int | None

**known_structs:** dict[str, *SimStruct*]

**memo:** dict[str, *Struct*]

**named_struct_id_counter**

**struct_name_to_idx**

**structs**

**translated:** dict[*TypeConstant*, *SimType*]

**translated_simtypes:** dict[*SimType*, *TypeConstant*]

### angr.go.typehoon.typehoon

**class** angr.go.typehoon.typehoon.**GoTypehoon**

Bases: *Typehoon*

Go-aware type inference engine: solutions come back as Go SimTypes.

## 10.21.11 angr.go.utils

### Submodules

| | |
|---|---|
| *copies* | |
| *graph* | |
| *multiword* | Multi-word Go values that live in one virtual variable rather than in a combo register: stack-passed parameters and stack results under the all-stack ABI0 (386). |
| *names* | |
| *types* | |
| *version* | |

### angr.go.utils.copies

angr.go.utils.copies.**copy_roots**(*graph*)

For each virtual variable, the one variable it copies through plain copies and phis, when that is unambiguous. Cyclic phi webs (loop-carried registers and spill slots) resolve to the single value entering them.

**Return type**
dict[int, *VirtualVariable*]

**Parameters**
**graph** (*DiGraph*)

### angr.go.utils.graph

angr.go.utils.graph.**is_jump_only**(*block*)

**Return type**
bool

**Parameters**
**block** (Block)

angr.go.utils.graph.**conditional_pred**(*graph*, *block*)

The block whose conditional jump leads to `block`, looking through trampoline (jump-only) blocks.

**Return type**
Block | None

**Parameters**

- **graph** (*networkx.DiGraph*)
- **block** (Block)

angr.go.utils.graph.**skip_jumps**(*graph*, *block*)

Follow trampoline blocks until a block that does something.

**Return type**
Block

**Parameters**

- **graph** (*networkx.DiGraph*)
- **block** (Block)

angr.go.utils.graph.**leads_to**(*graph*, *block*, *target*)

Whether `block` is `target` or a trampoline chain ending at it.

**Return type**
bool

**Parameters**

- **graph** (*networkx.DiGraph*)
- **block** (Block)
- **target** (Block)

angr.go.utils.graph.**block_before**(*graph*, *block*, *target*)

The last block of the trampoline chain from `block` to `target` (`block` itself when it is adjacent).

**Return type**
Block | None

**Parameters**

- **graph** (*networkx.DiGraph*)
- **block** (Block)
- **target** (Block)

### angr.go.utils.multiword

Multi-word Go values that live in one virtual variable rather than in a combo register: stack-passed parameters and stack results under the all-stack ABI0 (386). The body reads their words as `Extract(v, k)`.

angr.go.utils.multiword.**extract_piece**(*expr*)

`Extract(v, k)` -> (v, k) in bytes.

**Return type**
tuple[*VirtualVariable*, int] | None

**Parameters**
**expr** (Expression)

angr.go.utils.multiword.**multiword_vvars**(*pass_*)

varid -> Go struct type of every virtual variable holding a whole string/slice/interface/tuple value: parameters typed by the prototype, results of calls with a typed result, and copies of either.

**Return type**
dict[int, *SimType*]

**class** angr.go.utils.multiword.**VVarUseCounter**

Bases: *AILBlockViewer*

Occurrences of every virtual variable (a definition counts as one).

**__init__**()

angr.go.utils.multiword.**vvar_use_counts**(*graph*)

**Return type**
dict[int, int]

### angr.go.utils.names

angr.go.utils.names.**is_go_morestack_name**(*name*)

**Return type**
bool

**Parameters**
**name** (*str | None*)

angr.go.utils.names.**is_go_morestack_call**(*project*, *call*)

Whether `call` targets a goroutine stack-growth stub, identified by name or (in binaries without names) by the shape-based identification CFGFast records.

**Return type**
bool

**Parameters**
**call** (Call)

angr.go.utils.names.**call_target_name**(*project*, *call*)

The name of the function a call targets, or None if the target is not a known function.

**Return type**
str | None

**Parameters**
**call** (Call)

angr.go.utils.names.**is_go_closure_name**(*name*)

`pkg.f.func1`, `pkg.f.gowrap2`, `pkg.T.M-fm`: bodies that receive a closure context.

**Return type**
bool

**Parameters**
**name** (*str | None*)

angr.go.utils.names.**split_go_func_name**(*name*)

`pkg/path.(*T[A]).M` -> `("pkg/path", ["(*T[A])", "M"])`: the package path, then the dot-separated parts after it. Dots, commas and slashes inside type arguments (`F[go.shape.struct { a.B }]`) do not split.

**Return type**
tuple[str, list[str]] | None

**Parameters**
**name** (*str*)

angr.go.utils.names.**split_go_method_name**(*name*)

`pkg.(*T).M` -> `(pkg, "T", True, "M")`, `pkg.T[A].M` -> `(pkg, "T[A]", False, "M")`; None for plain functions and closures (`pkg.f.func1`, `pkg.T.M-fm`).

**Return type**
tuple[str, str, bool, str] | None

**Parameters**
**name** (*str*)

### angr.go.utils.types

angr.go.utils.types.**simtype_signed**(*ty*, *default=None*)

`ty.signed` for the SimTypes that have a signedness, `default` for any other type (or None).

angr.go.utils.types.**go_type_name_at**(*project*, *addr*)

The Go spelling of the runtime type descriptor at `addr` (`main.node`, `*main.node`, `[]int`), from the parsed descriptor table when available, otherwise from DWARF or a `type:...` symbol.

**Return type**
`str | None`

**Parameters**

- **project** (`Project`)
- **addr** (*int*)

angr.go.utils.types.**go_type_at**(*project*, *addr*)

The SimType of the runtime type descriptor at `addr`, or None when it is not a known descriptor.

**Return type**
*SimType* | `None`

**Parameters**

- **project** (`Project`)
- **addr** (*int*)

### angr.go.utils.version

**type** angr.go.utils.version.**GoVersionRange** = **tuple**[**tuple**[**int**, **int**], **tuple**[**int**, **int**] | **None**]

angr.go.utils.version.**go_minor_version**(*version*)

`go1.22.5` -> `go1.22`.

**Return type**
`str`

**Parameters**
**version** (*str*)

angr.go.utils.version.**identify_go_version**(*project*)

The Go release a binary was built with (`go1.22.5`), from runtime.buildVersion, the build-info blob, or the first release marker in read-only data. Failing those, the oldest release that emits the binary's pclntab layout (`go1.16`), which is only a lower bound.

**Return type**
`str | None`

**Parameters**
**project** (`Project`)

angr.go.utils.version.**parse_go_version**(*version*)

`go1.22.5` -> `(1, 22)`.

**Return type**
`tuple[int, int] | None`

**Parameters**
**version** (*str*)

angr.go.utils.version.**go_version_range**(*project*)

The (oldest, newest) Go releases (`(major, minor)`) the binary may have been built with. Both are the same when the exact release is known; otherwise they span the releases that emit its pclntab layout, and newest is None when that layout is still current. None if nothing identifies the release.

**Return type**
| None

**Parameters**
**project** (Project)

angr.go.utils.version.**identify_goos**(*project*)

The binary's GOOS, when its container format tells; None otherwise.

**Return type**
str | None

**Parameters**
**project** (Project)

## 10.22 angr.keyed_region

**class** angr.keyed_region.**StoredObject**

Bases: object

**__init__**(*start*, *obj*, *size*)

**start**

**obj**

**size**: *UnknownSize* | int

**property obj_id**

**class** angr.keyed_region.**RegionObject**

Bases: object

Represents one or more objects occupying one or more bytes in KeyedRegion.

**__init__**(*start*, *size*, *objects=None*)

**start**

**size**

**stored_objects**

**property is_empty**

**property end**

**property internal_objects**

**includes**(*offset*)

**split**(*split_at*)

**add_object**(*obj*)

set_object(*obj*)

remove_object(*obj*)

**Return type**
None

copy(*obj_mapper=None*)

**Parameters**
**obj_mapper** (*Callable[[Any], Any] | None*)

class angr.keyed_region.**KeyedRegion**

Bases: object

KeyedRegion keeps a mapping between stack offsets and all objects covering that offset. It assumes no variable in this region overlap with another variable in this region.

Registers and function frames can all be viewed as a keyed region.

__init__(*tree=None*, *phi_node_contains=None*, *canonical_size=8*)

copy(*obj_mapper=None*)

Copy this region. With obj_mapper, every stored object is replaced by obj_mapper(obj).

**Parameters**
**obj_mapper** (*Callable[[Any], Any] | None*)

merge(*other*, *replacements=None*)

Merge another KeyedRegion into this KeyedRegion.

**Parameters**
**other** (KeyedRegion) – The other instance to merge with.

**Returns**
None

merge_to_top(*other*, *replacements=None*, *top=None*)

Merge another KeyedRegion into this KeyedRegion, but mark all variables with different values as TOP.

**Parameters**

- **other** – The other instance to merge with.
- **replacements**

**Returns**
self

replace(*replacements*)

Replace variables with other variables.

**Parameters**
**replacements** (*dict*) – A dict of variable replacements.

**Returns**
self

dbg_repr()

Get a debugging representation of this keyed region. :return: A string of debugging output.

**add_variable**(*start*, *variable*)

Add a variable to this region at the given offset.

**Parameters**

- **start** (*int*)
- **variable** (SimVariable)

**Returns**
None

**add_object**(*start*, *obj*, *object_size*)

Add/Store an object to this region at the given offset.

**Parameters**

- **start**
- **obj**
- **object_size** (*int*) – Size of the object

**Returns**

**set_variable**(*start*, *variable*)

Add a variable to this region at the given offset, and remove all other variables that are fully covered by this variable.

**Parameters**

- **start** (*int*)
- **variable** (SimVariable)

**Returns**
None

**set_object**(*start*, *obj*, *object_size*)

Add an object to this region at the given offset, and remove all other objects that are fully covered by this object.

**Parameters**

- **start**
- **obj**
- **object_size**

**Returns**

**remove_variable**(*start*, *variable*)

Remove a variable that was added at the given offset. Other variables are untouched.

**Return type**
None

**remove_object**(*start*, *obj*, *object_size*)

**Return type**
None

**get_base_addr**(*addr*)

Get the base offset (the key we are using to index objects covering the given offset) of a specific offset.

**Parameters**
**addr** (*int*)

**Returns**

**Return type**
int or None

**get_variables_by_offset**(*start*)

Find variables covering the given region offset.

**Parameters**
**start** (*int*)

**Returns**
A set of variables.

**Return type**
set

**get_objects_by_offset**(*start*)

Find objects covering the given region offset.

**Parameters**
**start**

**Returns**

**get_all_variables**()

Get all variables covering the current region.

**Returns**
A set of all variables.

## 10.23 angr.knowledge_base

Representing the artifacts of a project.

**class** angr.knowledge_base.**KnowledgeBase**

Bases: object

Represents a "model" of knowledge about an artifact.

Contains things like a CFG, data references, etc.

**functions:** *FunctionManager*

**comments:** *Comments*

**bookmarks:** *Bookmarks*

**variables:** *VariableManager*

**defs:** *KeyDefinitionManager*

**cfgs:** *CFGManager*

**types:** *TypesStore*

**propagations:** *PropagationManager*

**xrefs:** *XRefManager*

**decompilations:** *StructuredCodeManager*

**obfuscations:** *Obfuscations*

**rtdb:** *RuntimeDb*

**__init__**(*project*, *obj=None*, *name=None*)

**property callgraph**

**property unresolved_indirect_jumps**

**property resolved_indirect_jumps**

**has_plugin**(*name*)

**get_plugin**(*name*)

**register_plugin**(*name*, *plugin*)

**release_plugin**(*name*)

**get_knowledge**[*K:* KnowledgeBasePlugin](*requested_plugin_cls*)

Type inference safe method to request a knowledge base plugin Explicitly passing the type of the requested plugin achieves two things: 1. Every location using this plugin can be easily found with an IDE by searching explicit references to the type 2. Basic type inference can deduce the result type and properly type check usages of it

If there isn't already an instance of this class None will be returned to make it clear to the caller that there is no existing knowledge of this type yet. The code that initially creates this knowledge should use the *register_plugin* method to register the initial knowledge state :type requested_plugin_cls: type[K] :param requested_plugin_cls:

**Return type**
Optional[K]

**Returns**
Instance of the requested plugin class or null if it is not a known plugin

**Parameters**
**requested_plugin_cls** (type*[K]*)

**request_knowledge**[*K:* KnowledgeBasePlugin](*requested_plugin_cls*)

**Return type**
K

**Parameters**
**requested_plugin_cls** (type*[K]*)

**class** angr.knowledge_base.**KnowledgeBaseSnapshot**

Bases: object

A restore point for a *KnowledgeBase*, so that the same project and CFG can be analyzed repeatedly (for example, decompiling one function under several option sets) from an identical starting state.

A snapshot records:

- the plugin table, as a shallow copy of the name-to-plugin mapping;
- by-value copies of the plugins named in `included_plugins` (default *COPIED_PLUGINS*) that exist at snapshot time;
- for each function resident in memory, its per-flavor prototypes, prototype sources, set of resolved flavors, and calling convention.

Without a rollback, a later `Decompiler` run sees the callee prototypes that Clinic installed on `Function` objects during an earlier run, inherits that run's variable numbering through `dec_variables`, and, when its cache parameters match, reuses the earlier `decompilations` entry instead of running the pipeline.

Functions are captured by object identity, and only the resident ones, because iterating a spilling function dict would evict the `Function` objects that callers hold. As a result, prototype changes on functions that were spilled at snapshot time and loaded later are not rolled back.

**COPIED_PLUGINS = ('types', 'custom_strings', 'callsite_prototypes', 'comments', 'variables')**

**__init__**(*kb*, *included_plugins=None*)

**Parameters**

- **kb** (*KnowledgeBase*) – The knowledge base to snapshot.
- **included_plugins** (Iterable[str] | None) – Names of the plugins to restore by value; the others are kept by reference. Defaults to *COPIED_PLUGINS*.

**restore**()

Roll the knowledge base back to this snapshot. Plugins created after the snapshot are removed. Each included plugin is replaced by a fresh copy of the snapshot's copy, so the snapshot itself is never modified. All other plugins are reinstated by reference, which means changes made to them in place are kept. Resident functions get their prototype state back. This method may be called any number of times.

**Return type**
None

## 10.24 angr.knowledge_plugins

**class** angr.knowledge_plugins.**Bookmark**

Bases: object

A user-marked address with an optional label.

**__init__**(*addr*, *label=''*, *created_at=None*)

**Parameters**

- **addr** (*int*)
- **label** (*str*)
- **created_at** (*float | None*)

**Return type**
None

**addr**

**label**

**created_at**

**class** angr.knowledge_plugins.**Bookmarks**

Bases: *KnowledgeBasePlugin*, list

Tracks bookmarks as a list of Bookmark, in creation order.

**get_bookmark**(*addr*)

**Return type**
*Bookmark* | None

**Parameters**
**addr** (*int*)

**has_bookmark**(*addr*)

**Return type**
bool

**Parameters**
**addr** (*int*)

**add_bookmark**(*addr*, *label=''*)

Bookmark addr, or relabel the bookmark already there if label is non-empty. Returns the bookmark and whether it was newly created.

**Return type**
tuple[*Bookmark*, bool]

**Parameters**

- **addr** (*int*)
- **label** (*str*)

**remove_bookmark**(*bookmark*)

Remove bookmark if present. Returns whether it was removed.

**Return type**
bool

**Parameters**
**bookmark** (Bookmark)

**toggle_bookmark**(*addr*, *label=''*)

Add a bookmark at addr, or remove the one already there. Returns the new one, if any.

**Return type**
*Bookmark* | None

**Parameters**

- **addr** (*int*)
- **label** (*str*)

**sorted_bookmarks**()

**Return type**
list[*Bookmark*]

**next_bookmark**(*after_addr*)

The next bookmark by address, wrapping around.

**Return type**
*Bookmark* | None

**Parameters**
**after_addr** (*int | None*)

class angr.knowledge_plugins.**CFGManager**

Bases: *KnowledgeBasePlugin*

This is the CFG manager, it manages CFGs

**__init__**(*kb*)

**new_model**(*prefix*, *addr_type='int'*)

**Parameters**
**addr_type** (*CFG_ADDR_TYPES*)

**copy**()

**get_most_accurate**()

**Return type**
*CFGModel* | None

**Returns**
The most accurate CFG present in the CFGManager, or None if it does not hold any.

class angr.knowledge_plugins.**CallsitePrototypes**

Bases: *KnowledgeBasePlugin*

CallsitePrototypes manages callee prototypes at call sites, per decompilation flavor. Every method takes a flavor (None: the default flavor). A non-default flavor reads its own entry of a kind at a call site, or the default flavor's entry of that kind when it has none, like Function.get_prototype().

**__init__**(*kb*)

**property flavors: list[str]**

The flavors that have entries of their own.

**set_prototype**(*callsite_block_addr*, *cc*, *prototype*, ***, *kind=CallsitePrototypeKind.INFERRED*, *manual=False*, *propagated=False*, *flavor=None*)

**Return type**
None

**Parameters**

- **callsite_block_addr** (*int*)
- **cc** (SimCC)
- **prototype** (SimTypeFunction)
- **kind** (CallsitePrototypeKind)
- **manual** (*bool*)
- **propagated** (*bool*)
- **flavor** (*str | None*)

**remove_prototype**(*callsite_block_addr*, *, *kind=CallsitePrototypeKind.INFERRED*, *flavor=None*)

Remove the flavor's own entry of a kind; a non-default flavor then falls back to the default one.

**Return type**
None

**Parameters**

- **callsite_block_addr** (*int*)
- **kind** (CallsitePrototypeKind)
- **flavor** (*str | None*)

**get_cc**(*callsite_block_addr*, *, *kind=CallsitePrototypeKind.INFERRED*, *flavor=None*)

**Return type**
*SimCC* | None

**Parameters**

- **callsite_block_addr** (*int*)
- **kind** (CallsitePrototypeKind)
- **flavor** (*str | None*)

**get_prototype**(*callsite_block_addr*, *, *kind=CallsitePrototypeKind.INFERRED*, *flavor=None*)

**Return type**
*SimTypeFunction* | None

**Parameters**

- **callsite_block_addr** (*int*)
- **kind** (CallsitePrototypeKind)
- **flavor** (*str | None*)

**is_prototype_manual**(*callsite_block_addr*, *, *flavor=None*)

**Return type**
bool | None

**Parameters**

- **callsite_block_addr** (*int*)
- **flavor** (*str | None*)

**is_prototype_certain**(*callsite_block_addr*, *, *flavor=None*)

**Return type**
bool | None

**Parameters**

- **callsite_block_addr** (*int*)
- **flavor** (*str | None*)

**has_some_prototype**(*callsite_block_addr*, *, *flavor=None*)

**Return type**
bool

**Parameters**

- **callsite_block_addr** (*int*)
- **flavor** (*str | None*)

**has_prototype**(*callsite_block_addr*, ***, *kind=CallsitePrototypeKind.INFERRED*, *flavor=None*)

**Return type**
bool

**Parameters**

- **callsite_block_addr** (*int*)
- **kind** (CallsitePrototypeKind)
- **flavor** (*str | None*)

**has_prototype_for_flavor**(*callsite_block_addr*, ***, *kind=CallsitePrototypeKind.INFERRED*, *flavor=None*)

Whether the flavor has its own entry of the kind (as opposed to falling back to the default flavor's).

**Return type**
bool

**Parameters**

- **callsite_block_addr** (*int*)
- **kind** (CallsitePrototypeKind)
- **flavor** (*str | None*)

**items**(*flavor=None*)

The flavor's own entries (no fallback).

**Return type**
Iterator[tuple[int, *CallsitePrototypeKind*, *SimCC*, *SimTypeFunction*]]

**Parameters**
**flavor** (*str | None*)

**copy**()

class angr.knowledge_plugins.**Comment**

Bases: object

A comment together with its display metadata. Rebuilt on demand from the knowledge base.

**__init__**(*addr*, *text*, *kind*, *func_addr=None*, *func_name=None*)

**Parameters**

- **addr** (*int*)
- **text** (*str*)
- **kind** (CommentKind)
- **func_addr** (*int | None*)
- **func_name** (*str | None*)

**Return type**
None

**addr**

**text**

**kind**

**func_addr**

**func_name**

**property first_line:** *str*

**class** angr.knowledge_plugins.**CommentKind**

Bases: IntEnum

How a comment is displayed.

PLAIN shows only at its own address. FUNCTION renders as a header block above the function, which is also what the decompiler does with a comment on a function entry. REPEATABLE additionally shows at every location referencing the commented address.

**PLAIN = 0**

**FUNCTION = 1**

**REPEATABLE = 2**

**property display_name:** *str*

**__new__**(*value*)

**class** angr.knowledge_plugins.**Comments**

Bases: *KnowledgeBasePlugin*, dict

Tracks comments via a Dict of Address -> Text, along with a per-address CommentKind.

**property kinds:** *dict[int, CommentKind]*

Explicitly-set comment kinds. Addresses not present here use kind_of() defaults.

**kind_of**(*addr*)

**Return type**
*CommentKind*

**Parameters**
**addr** (*int*)

**set_kind**(*addr*, *kind*)

Set the display kind for the comment at addr, or reset it to the default with None.

**Return type**
None

**Parameters**

- **addr** (*int*)
- **kind** (CommentKind | *None*)

**is_function_entry**(*addr*)

**Return type**
bool

**Parameters**
**addr** (*int*)

**function_comment**(*func_addr*)

The comment rendered as a function's header block, if any.

**Return type**
str | None

**Parameters**
**func_addr** (*int*)

**inline_comment**(*addr*)

The comment rendered next to the instruction at `addr`. A comment that already renders as a function header block is not repeated inline.

**Return type**
str | None

**Parameters**
**addr** (*int*)

**iter_comments**()

All comments in address order, with their kinds and owning functions.

**Return type**
Iterator[*Comment*]

**repeatable_comments_at**(*ins_addr*)

Repeatable comments that should show at `ins_addr` because it references their address.

**Return type**
list[tuple[int, str]]

**Parameters**
**ins_addr** (*int*)

**invalidate**()

Drop the cached repeatable-comment map, e.g. after xrefs or functions change.

**Return type**
None

**class** angr.knowledge_plugins.**CustomStrings**

Bases: *KnowledgeBasePlugin*

Store new strings that are recovered during various analysis. Each string has a unique ID associated.

**__init__**(*kb*)

**allocate**(*s*)

**Return type**
int

**Parameters**
**s** (bytes)

copy()

class angr.knowledge_plugins.Data

Bases: KnowledgeBasePlugin

The knowledge what purpose this plugin serves has been lost to the passing of time but the linter does not care for these failures of mere mortals and demands a docstring anyway. The pact has been made, and no violations of the rules will be tolerated, even if the spirit does not match the letter. Making the plugin smaller has only increased the weight of the failure, and thus this file has drawn its ire.

The only thing left to do is to attempt to find meaning in the meaninglessness, as the only act of rebellion against the uncaring forces that bind us. For is this not what being human is all about?

copy()

class angr.knowledge_plugins.DebugVariableManager

Bases: KnowledgeBasePlugin

Structure to manage and access variables with different visibility scopes.

__init__(*kb*)

**Parameters**
**kb** (KnowledgeBase)

from_name_and_pc(*var_name*, *pc_addr*)

Get a variable from its string in the scope of pc.

**Return type**
Variable

**Parameters**

- **var_name** (*str*)
- **pc_addr** (*int*)

from_name(*var_name*)

Get the variable container for all variables named var_name

**Parameters**
**var_name** (str) – name for a variable

**Return type**
*DebugVariableContainer*

add_variable(*cle_var*, *low_pc*, *high_pc*)

Add/load a variable

**Parameters**

- **cle_variable** – The variable to add
- **low_pc** (int) – Start of the visibility scope of the variable as program counter address (rebased)
- **high_pc** (int) – End of the visibility scope of the variable as program counter address (rebased)
- **cle_var** (*Variable*)

**add_variable_list**(*vlist*, *low_pc*, *high_pc*)

Add all variables in a list with the same visibility range

**Parameters**

- **vlist** (list[Variable]) – A list of cle variables to add
- **low_pc** (int) – Start of the visibility scope as program counter address (rebased)
- **high_pc** (int) – End of the visibility scope as program counter address (rebased)

**load_from_dwarf**(*elf_object=None*, *cu=None*)

Automatically load all variables (global/local) from the DWARF debugging info

**Parameters**

- **elf_object** (ELF) – Optional, when only one elf object should be considered (e.g. p.loader.main_object)
- **cu** (CompilationUnit) – Optional, when only one compilation unit should be considered

**class** angr.knowledge_plugins.**Function**

Bases: *Serializable*

A representation of a function and various information about it.

**Variables**

- **meta_only** – Whether this function only contains meta-information and in read-only mode.
- **_dirty** – Whether this function has been modified since last serialization.
- **evicted** – Whether this function has been evicted from FunctionManager to external storage.

**__init__**(*function_manager*, *addr*, *name=None*, *syscall=None*, *is_simprocedure=None*, *binary_name=None*, *is_plt=None*, *returning=None*, *alignment=False*, *calling_convention=None*, *prototype=None*, *prototype_libname=None*, *prototype_source=None*, *is_prototype_guessed=True*)

Function constructor. If the optional parameters are not provided, they will be automatically determined upon the creation of a Function object.

**Parameters**

- **addr** (int) – The address of the function.
- **name** (*str*) – The name of the function.
- **syscall** (*bool*) – Whether this function is a syscall or not.
- **is_simprocedure** (bool | None) – Whether this function is a SimProcedure or not.
- **binary_name** (*str*) – Name of the binary where this function is.
- **is_plt** (bool | None) – If this function is a PLT entry.
- **returning** (*bool*) – If this function returns.
- **alignment** (*bool*) – If this function acts as an alignment filler. Such functions usually only contain nops.
- **function_manager** (FunctionManager | *None*)
- **calling_convention** (SimCC | *None*)
- **prototype** (SimTypeFunction | *None*)
- **prototype_libname** (*str* | *None*)

- **prototype_source** (PrototypeSource | *None*)
- **is_prototype_guessed** (*bool*)

**is_default_name**

**binary_name**

**property name**

**property from_signature:** str | None

**property project:** *Project* | None

**property returning**

**property calling_convention:** *SimCC* | None

**property prototypes:** dict[str, *SimTypeFunction* | None]

A snapshot of every flavor's prototype, keyed by decompilation flavor. Write through set_prototype(); the default-flavor entry is also exposed as .prototype.

**property prototype_sources:** dict[str, *PrototypeSource*]

A snapshot of every flavor's prototype source; the default-flavor entry is also exposed as .prototype_source.

**property prototype:** *SimTypeFunction* | None

**get_prototype**(*flavor*)

The prototype a decompilation of the given flavor should use: the flavor's own entry, or the C prototype when the flavor has none. The C flavor never falls back to another flavor.

**Return type**
*SimTypeFunction* | None

**Parameters**
**flavor** (*str* | *None*)

**has_prototype_for_flavor**(*flavor*)

Whether the flavor has its own entry (as opposed to falling back to the C prototype).

**Return type**
bool

**Parameters**
**flavor** (*str* | *None*)

**uses_default_prototype_for**(*flavor*)

Whether get_prototype(flavor) is the default flavor's (C) prototype, e.g., to dereference it by library.

**Return type**
bool

**Parameters**
**flavor** (*str* | *None*)

**get_prototype_source**(*flavor*)

The source of the prototype get_prototype(flavor) returns.

**Return type**
*PrototypeSource*

**Parameters**
**flavor** (*str | None*)

**set_prototype**(*flavor*, *proto*, *source=None*)

Set the prototype of a flavor. A flavor's first entry starts with the source of the prototype it used to fall back to (the C one) unless `source` is given.

**Return type**
None

**Parameters**

- **flavor** (*str | None*)
- **proto** (SimTypeFunction | *None*)
- **source** (PrototypeSource | *None*)

**set_prototype_source**(*flavor*, *source*)

Set the source of a flavor's prototype; a flavor without an entry gets one that falls back to C's.

**Return type**
None

**Parameters**

- **flavor** (*str | None*)
- **source** (PrototypeSource)

**clear_prototype**(*flavor*)

Drop a flavor's own entry so that it falls back to the C prototype; clearing C sets it to None.

**Return type**
None

**Parameters**
**flavor** (*str | None*)

**property prototype_libname**

**Setter accepts**
str | None

**property is_prototype_guessed: bool**

**is_prototype_guessed_for**(*flavor*)

**Return type**
bool

**Parameters**
**flavor** (*str | None*)

**property is_prototype_groundtruth: bool**

True if the prototype comes from outside of the decompiler (SimProcedures, signatures, or the user) and may be fed back into type inference as ground truth. Prototypes inferred by the decompiler itself are excluded so that re-decompiling a function does not freeze its own earlier guess.

**is_prototype_groundtruth_for**(*flavor*)

is_prototype_groundtruth for the prototype get_prototype(flavor) returns.

**Return type**
bool

**Parameters**
**flavor** (*str | None*)

**property prototype_source:** *PrototypeSource*

**property info:** *FunctionInfo*

**Setter accepts**
*FunctionInfo* | dict

**property is_plt:** bool

**property is_simprocedure:** bool

**property is_syscall:** bool

**property is_alignment:** bool

**transition_out_edges**(*node*)

(successor, edge data) pairs of a node, in the order of `transition_graph.out_edges(node, data=True)`, without building the networkx transition graph when it does not exist yet.

**Return type**
list[tuple[*CodeNode*, Mapping[str, Any]]]

**Parameters**
**node** (CodeNode)

**transition_in_edges**(*node*)

(predecessor, edge data) pairs of a node, in the order of `transition_graph.in_edges(node, data=True)`, without building the networkx transition graph when it does not exist yet.

**Return type**
list[tuple[*CodeNode*, Mapping[str, Any]]]

**Parameters**
**node** (CodeNode)

**has_node**(*node*)

**Return type**
bool

**Parameters**
**node** (CodeNode)

**set_edge_outside**(*src*, *dst*, *outside*)

**Return type**
None

**Parameters**

- **src** (CodeNode)
- **dst** (CodeNode)
- **outside** (*bool*)

**add_graph_node**(*node*)

Add a node to the transition graph without registering it as a local block.

**Return type**
None

**Parameters**
**node** (CodeNode)

**add_graph_edge**(*src*, *dst*, *type=None*, *outside=None*, *ins_addr=<object object>*, *stmt_idx=<object object>*, *confirmed=None*)

Add or update an edge of the transition graph.

**Return type**
None

**Parameters**

- **src** (CodeNode)
- **dst** (CodeNode)
- **type** (*str | None*)
- **outside** (*bool | None*)
- **ins_addr** (*int | None*)
- **stmt_idx** (*int | None*)
- **confirmed** (*bool | None*)

**remove_graph_node**(*node*)

Remove a node and its edges from the transition graph.

**Return type**
None

**Parameters**
**node** (CodeNode)

**set_edge_confirmed**(*src*, *dst*, *confirmed*)

**Return type**
None

**Parameters**

- **src** (CodeNode)
- **dst** (CodeNode)
- **confirmed** (*bool*)

**property transition_graph:** *TransitionGraph*

A read-only networkx view of the transition graph, created on-demand and kept in sync with the Function's updates.

**property startpoint:** *CodeNode* | None

**property blocks**

An iterator of all local blocks in the current function.

**Returns**
angr.lifter.Block instances.

**property code_nodes:** dict[int, *CodeNode*]

**property cyclomatic_complexity**

The cyclomatic complexity of the function.

Cyclomatic complexity is a software metric used to indicate the complexity of a program. It is a quantitative measure of the number of linearly independent paths through a program's source code. It is computed using the formula: M = E - N + 2P, where E = the number of edges in the graph, N = the number of nodes in the graph, P = the number of connected components.

The cyclomatic complexity value is lazily computed and cached for future use. Initially this value is None until it is computed for the first time

**Returns**
The cyclomatic complexity of the function.

**Return type**
int

**property xrefs: Iterator[*XRef*]**

An iterator of all xrefs of the current function.

**Returns**
angr.knowledge_plugins.xrefs.xref.XRef instances.

**property block_addrs**

An iterator of all local block addresses in the current function.

**Returns**
block addresses.

**property block_addrs_set**

Return a set of block addresses for a better performance of inclusion tests.

**Returns**
A set of block addresses.

**Return type**
set

**get_block**(*addr*, *size=None*, *byte_string=None*)

Getting a block out of the current function.

**Parameters**

- **addr** (int) – The address of the block.
- **size** (int | None) – The size of the block. This is optional. If not provided, angr will load
- **byte_string** (bytes | None)

**Returns**

**get_block_size**(*addr*)

**Return type**
int | None

**Parameters**
**addr** (*int*)

**property nodes: Iterable[*CodeNode*]**

**get_node**(*addr*)

**Return type**
*BlockNode* | None

**property has_unresolved_jumps**

**property has_unresolved_calls**

**property operations**
All of the operations that are done by this functions.

**property code_constants**
All of the constants that are used by this functions's code.

**classmethod parse_from_cmessage**(*cmsg*, ***kwargs*)

**Parameters**
**cmsg**

**Return Function**
The function instantiated out of the cmsg data.

**string_references**(*minimum_length=2*)
All of the constant string references used by this function.

**Parameters**
**minimum_length** – The minimum length of strings to find (default is 1)

**Returns**
A generator yielding tuples of (address, string) where is address is the location of the string in memory.

**property local_runtime_values**
Tries to find all runtime values of this function which do not come from inputs. These values are generated by starting from a blank state and reanalyzing the basic blocks once each. Function calls are skipped, and back edges are never taken so these values are often unreliable, This function is good at finding simple constant addresses which the function will use or calculate.

**Returns**
a set of constants

**property num_arguments**

**property endpoints: list[*CodeNode*]**

**property endpoints_with_type: defaultdict[str, set[*CodeNode*]]**

**property ret_sites: list[*CodeNode*]**

**property jumpout_sites: list[*CodeNode*]**

**property retout_sites: list[*CodeNode*]**

**property callout_sites: list[*CodeNode*]**

**property size**

**property binary**
Get the object this function belongs to. :return: The object this function belongs to.

**property offset: int**

the function's binary offset (i.e., non-rebased address)

**Type**
return

**property symbol: Symbol | None**

the function's Symbol, if any

**Type**
return

**property pseudocode: str | None**

the function's pseudocode

**Type**
return

**property dirty: bool**

**mark_dirty**()

**Return type**
None

**add_jumpout_site**(*node*)

Add a custom jumpout site.

**Parameters**
**node** (*CodeNode*) – The address of the basic block that control flow leaves during this transition.

**Returns**
None

**add_retout_site**(*node*)

Add a custom retout site.

Retout (returning to outside of the function) sites are very rare. It mostly occurs during CFG recovery when we incorrectly identify the beginning of a function in the first iteration, and then correctly identify that function later in the same iteration (function alignments can lead to this bizarre case). We will mark all edges going out of the header of that function as a outside edge, because all successors now belong to the incorrectly-identified function. This identification error will be fixed in the second iteration of CFG recovery. However, we still want to keep track of jumpouts/retouts during the first iteration so other logic in CFG recovery still work.

**Parameters**
**node** (*CodeNode*) – The address of the basic block that control flow leaves the current function after a call.

**Returns**
None

**clear_transition_graph**()

**confirm_fakeret**(*src*, *dst*)

**transit_to**(*from_node*, *to_node*, *outside=False*, *ins_addr=None*, *stmt_idx=None*, *is_exception=False*, *update_func_block_count=True*)

Registers an edge between basic blocks in this function's transition graph. Arguments are CodeNode objects.

**Parameters**

- **from_node** (*CodeNode*) – The address of the basic block that control flow leaves during this transition.
- **to_node** – The address of the basic block that control flow enters during this transition.
- **outside** (*bool*) – If this is a transition to another function, e.g. tail call optimization
- **update_func_block_count** (*bool*)

**Returns**
None

**call_to**(*from_node*, *to_func*, *ret_node*, *stmt_idx=None*, *ins_addr=None*, *return_to_outside=False*, *syscall=False*, *update_func_block_count=True*)

Registers an edge between the caller basic block and callee function.

**Parameters**

- **from_node** (*angr.knowledge.CodeNode*) – The basic block that control flow leaves during the transition.
- **to_func** (*FuncNode* | *HookNode*) – The function that we are calling, represented as a FuncNode.
- **ret_node** (*angr.knowledge.CodeNode or None*) – The basic block that control flow should return to after the function call.
- **stmt_idx** (*int, str or None*) – Statement ID of this call.
- **ins_addr** (*int or None*) – Instruction address of this call.
- **syscall** (*bool*)
- **update_func_block_count** (*bool*)

**fakeret_to**(*from_node*, *to_node*, *confirmed=None*, *to_outside=False*, *update_func_block_count=True*)

**Parameters**
**update_func_block_count** (*bool*)

**remove_fakeret**(*from_node*, *to_node*)

**remove_edge**(*from_node*, *to_node*)

**Return type**
None

**Parameters**

- **from_node** (CodeNode)
- **to_node** (CodeNode)

**return_from_call**(*from_func*, *to_node*, *to_outside=False*, *confirm_fakeret=True*)

**Parameters**

- **from_func** (FuncNode | HookNode)
- **confirm_fakeret** (*bool*)

**update_func_block_count**()

Update the cached block count of this function in the function manager.

**Return type**
None

**register**(*is_local*, *node*, *update_func_block_count=True*)

Register a node with the function and return its ID. The first object that is registered for a fresh ID becomes the ID's canonical CodeNode object.

**Return type**
int

**Parameters**

- **is_local** (*bool*)
- **node** (CodeNode)
- **update_func_block_count** (*bool*)

**register_node**(*is_local*, *node*, *update_func_block_count=True*)

**Return type**
*CodeNode*

**Parameters**

- **is_local** (*bool*)
- **node** (CodeNode)
- **update_func_block_count** (*bool*)

**add_return_site**(*return_site*)

Registers a basic block as a site for control flow to return from this function.

**Parameters**
**return_site** (*CodeNode*) – The block node that ends with a return.

**add_call_site**(*call_site_addr*, *call_target_addr*, *retn_addr*)

Registers a basic block as calling a function and returning somewhere.

**Parameters**

- **call_site_addr** – The address of a basic block that ends in a call.
- **call_target_addr** – The address of the target of said call.
- **retn_addr** – The address that said call will return to.

**add_endpoint**(*endpoint_node*, *sort*)

Registers an endpoint with a type of *sort*. The type can be one of the following: - call: calling a function that does not return - return: returning from the current function - transition: a jump/branch targeting a different function

It is possible for a block to act as two different sorts of endpoints. For example, consider the following block:

.text:0000000000024350 mov eax, 1 .text:0000000000024355 lock xadd [rdi+4], eax .text:000000000002435A retn

**VEX code:**

00 | —— IMark(0x424350, 5, 0) —— 01 | PUT(rax) = 0x0000000000000001 02 | PUT(rip) = 0x0000000000424355 03 | —— IMark(0x424355, 5, 0) —— 04 | t11 = GET:I64(rdi) 05 | t10 = Add64(t11,0x0000000000000004) 06 | t0 = LDle:I32(t10) 07 | t2 = Add32(t0,0x00000001) 08 | t(4,4294967295) = CASle(t10 :: (t0,None)->(t2,None)) 09 | t14 = CasCmpNE32(t4,t0) 10 | if (t14) { PUT(rip) = 0x424355; Ijk_Boring } 11 | PUT(cc_op) = 0x0000000000000003 12 | t15 = 32Uto64(t0) 13 | PUT(cc_dep1) = t15 14 | PUT(cc_dep2) = 0x0000000000000001 15 | t17 = 32Uto64(t0) 16 | PUT(rax) = t17 17 | PUT(rip) = 0x000000000042435a 18 | —— IMark(0x42435a, 1, 0) —— 19 | t6 = GET:I64(rsp) 20 | t7 = LDle:I64(t6) 21 | t8 = Add64(t6,0x0000000000000008) 22 | PUT(rsp) = t8 23 | t18 = Sub64(t8,0x0000000000000080) 24 | ====== AbiHint(0xt18, 128, t7) ====== NEXT: PUT(rip) = t7; Ijk_Ret

This block acts as both a return endpoint and a transition endpoint (transitioning to 0x424355).

**Parameters**

- **endpoint_node** – The endpoint node.
- **sort** – Type of the endpoint.

**Returns**

None

`mark_nonreturning_calls_endpoints()`

Iterate through all call edges in transition graph. For each call a non-returning function, mark the source basic block as an endpoint.

This method should only be executed once all functions are recovered and analyzed by CFG recovery, so we know whether each function returns or not.

**Returns**

None

`property call_sites: dict[int, tuple[int | None, int | None]]`

`call_edge_addrs()`

(call-site block address, callee address) of every call edge, in transition-graph order. Unlike call_sites, a block with several call targets contributes one pair per target.

**Return type**

list[tuple[int, int]]

`jumpout_targets()`

(jump-out site block address, target address, branch instruction address) of every transition that leaves this function, such as a tail jump. The instruction address is None when the CFG did not record it.

**Return type**

list[tuple[int, int, int | None]]

`unconfirmed_fakeret_edges()`

Fake-return edges that have not been confirmed by a return of the callee, in transition-graph order.

**Return type**

list[tuple[*CodeNode*, *CodeNode*]]

`outgoing_function_targets()`

Addresses of the functions this function calls or jumps out to.

**Return type**

list[int]

**get_call_sites**()

Gets a list of all the basic blocks that end in calls.

**Return type**
Iterable[int]

**Returns**
A view of the addresses of the blocks that end in calls.

**get_call_target**(*callsite_addr*)

Get the target of a call.

**Parameters**
**callsite_addr** – The address of a basic block that ends in a call.

**Returns**
The target of said call, or None if callsite_addr is not a callsite.

**get_call_return**(*callsite_addr*)

Get the hypothetical return address of a call.

**Parameters**
**callsite_addr** – The address of the basic block that ends in a call.

**Returns**
The likely return target of said call, or None if callsite_addr is not a callsite.

**property graph:** *TransitionGraph*

Get a local transition graph. A local transition graph is a transition graph that only contains nodes that belong to the current function. All edges, except for the edges going out from the current function or coming from outside the current function, are included.

The generated graph is a read-only view cached in self._local_transition_graph.

**Returns**
A local transition graph.

**graph_ex**(*exception_edges=True*)

Get a local transition graph with a custom configuration. A local transition graph is a transition graph that only contains nodes that belong to the current function. This method allows user to include certain types of edges and nodes, such as exception edges.

The generated graph is not cached. It is a mutable copy.

**Parameters**
**exception_edges** (*bool*) – Should exception edges and the nodes that are only reachable through exception edges be kept.

**Return type**
networkx.DiGraph[CodeNode]

**Returns**
A local transition graph with a special configuration.

**transition_graph_ex**(*exception_edges=True*)

Get a transition graph with a custom configuration. This method allows user to exclude certain types of edges together with the nodes that are only reachable through such edges, such as exception edges.

The generated graph is not cached.

**Parameters**
**exception_edges** (*bool*) – Should exception edges and the nodes that are only reachable through exception edges be kept.

**Returns**
A local transition graph with a special configuration.

**Return type**
networkx.DiGraph

**subgraph**(*ins_addrs*)

Generate a sub control flow graph of instruction addresses based on self.graph

**Parameters**
**ins_addrs** (*iterable*) – A collection of instruction addresses that should be included in the subgraph.

**Return networkx.DiGraph**
A subgraph.

**instruction_size**(*insn_addr*)

Get the size of the instruction specified by *insn_addr*.

**Parameters**
**insn_addr** (*int*) – Address of the instruction

**Return int**
Size of the instruction in bytes, or None if the instruction is not found.

**addr**

**bp_on_stack**

**evicted**

**meta_only**

**normalized**

**previous_names**

**ran_cca**

**retaddr_on_stack**

**sp_delta**

**tags**

**addr_to_instruction_addr**(*addr*)

Obtain the address of the instruction that covers @addr.

**Parameters**
**addr** (*int*) – An address.

**Returns**
Address of the instruction that covers @addr, or None if this addr is not covered by any instruction of this function.

**Return type**
int or None

**dbg_print**()

Returns a representation of the list of basic blocks in this function.

**dbg_draw**(*filename*)

Draw the graph and save it to a PNG file.

**property arguments**

**property has_return**

**property callable**

**normalize**()

Make sure all basic blocks in the transition graph of this function do not overlap. You will end up with a CFG that IDA Pro generates.

This method does not touch the CFG result. You may call CFG{Emulated, Fast}.normalize() for that matter.

**Returns**
None

**find_declaration**(*ignore_binary_name=False*, *binary_name_hint=None*)

Find the most likely function declaration from the embedded collection of prototypes, set it to self.prototype, and update self.calling_convention with the declaration.

**Parameters**

- **ignore_binary_name** (bool) – Do not rely on the executable or library where the function belongs to determine its source library. This is useful when working on statically linked binaries (because all functions will belong to the main executable). We will search for all libraries in angr to find the first declaration match.
- **binary_name_hint** (str | None) – Substring of the library name where this function might be originally coming from. Useful for FLIRT-identified functions in statically linked binaries.

**Return type**
bool

**Returns**
True if a declaration is found and self.prototype and self.calling_convention are updated. False if we fail to find a matching function declaration, in which case self.prototype or self.calling_convention will be kept untouched.

**is_rust_function**()

Determines if the function name follows Rust mangling conventions.

**property demangled_name**

**property short_name**

**get_unambiguous_name**(*display_name=None*)

Get a disambiguated function name.

**Parameters**
**display_name** (str | None) – Name to display, otherwise the function name.

**Return type**
str

**Returns**

The function name in one of the following forms:

- ::<name> when the function binary is the main object.
- ::<obj>::<name> when the function binary is not the main object.
- ::<addr>::<name> when the function binary is an unnamed non-main object, or when multiple functions with the same name are defined in the function binary.

**apply_definition**(*definition*, *calling_convention=None*)

**Return type**
None

**Parameters**

- **definition** (*str*)
- **calling_convention** (SimCC | type[SimCC] | *None*)

**functions_reachable**()

**Return type**
set[*Function*]

**Returns**
The set of all functions that can be reached from the function represented by self.

**holes**(*min_size=8*)

Find the number of non-consecutive areas in the function that are at least *min_size* bytes large.

**Return type**
int

**Parameters**
**min_size** (*int*)

**copy**()

**pp**(***kwargs*)

Pretty-print the function disassembly.

**class** angr.knowledge_plugins.**FunctionManager**

Bases: *KnowledgeBasePlugin*, Mapping[K, *Function*], Generic[K]

When cache_limit is set, the FunctionManager uses a SpillingFunctionDict that implements an LRU cache keeping only the most recently accessed N functions in memory, spilling others to an LMDB database on disk. This allows working with binaries that have more functions than can fit in memory.

**Parameters**
**cache_limit** (int | None) – Maximum number of functions to keep in memory. None means unlimited (no eviction). Default is None.

**__init__**(*kb*, *cache_limit=None*)

**Parameters**

- **kb** (KnowledgeBase)
- **cache_limit** (*int* | *None*)

**copy**()

clear()

get_default_cache_limit(*max_limit=5000*)

Get the default function cache limit based on the size of the binary.

**Return type**
int | None

**Returns**
The default cache limit; None means unlimited.

**Parameters**
**max_limit** (*int*)

is_plt_cached(*addr*)

**Return type**
bool

**Parameters**
**addr** (*int*)

get_binary_name_cached(*addr*)

**Return type**
str | None

**Parameters**
**addr** (*int*)

function_name_changed(*addr*, *old_name*, *new_name*)

Notify the FunctionManager that a function's name has changed.

**Parameters**

- **addr** (K) – Address of the function.
- **old_name** (str | None) – Old name of the function, or None if there is no old name.
- **new_name** (str) – New name of the function.

**Return type**
None

get_by_addr(*addr*, *meta_only=False*)

**Return type**
*Function*

**Parameters**
**meta_only** (*bool*)

get_by_name(*name*, *check_previous_names=False*)

**Return type**
Generator[*Function*]

**Parameters**

- **name** (*str*)
- **check_previous_names** (*bool*)

get_addrs_by_name(*name*, *check_previous_names=False*)

**Return type**
set[int]

**Parameters**

- **name** (*str*)
- **check_previous_names** (*bool*)

contains_addr(*addr*)

Decide if an address is handled by the function manager.

Note: this function is non-conformant with python programming idioms, but its needed for performance reasons.

**Parameters**
**addr** (*int*) – Address of the function.

ceiling_addr(*addr*)

Return the function who has the least address that is greater than or equal to *addr*.

**Parameters**
**addr** (K) – The address to query.

**Return type**
Optional[K]

**Returns**
A Function instance, or None if there is no other function after *addr*.

ceiling_func(*addr*)

Return the function who has the least address that is greater than or equal to *addr*.

**Parameters**
**addr** (*int*) – The address to query.

**Return type**
*Function* | None

**Returns**
A Function instance, or None if there is no other function after *addr*.

floor_addr(*addr*)

Return the function who has the greatest address that is less than or equal to *addr*.

**Parameters**
**addr** (K) – The address to query.

**Return type**
Optional[K]

**Returns**
An address, or None if there is no other function before *addr*.

floor_func(*addr*)

Return the function who has the greatest address that is less than or equal to *addr*.

**Parameters**
**addr** (*int*) – The address to query.

**Returns**
A Function instance, or None if there is no other function before *addr*.

**Return type**
*Function* or None

**query**(*query*, *check_previous_names=False*)

Query for a function using selectors to disambiguate. Supported variations:

::<name> Function <name> in the main object ::<addr>::<name> Function <name> at <addr> ::<obj>::<name> Function <name> in <obj>

**Return type**
*Function* | None

**Parameters**

- **query** (*str*)
- **check_previous_names** (*bool*)

**function**(*addr=None*, *name=None*, *check_previous_names=False*, *create=False*, *syscall=False*, *plt=None*)

Get a function object from the function manager.

Pass either *addr* or *name* with the appropriate values.

**Parameters**

- **addr** (Optional[K]) – Address of the function.
- **name** (str | None) – Name of the function.
- **create** (bool) – Whether to create the function or not if the function does not exist.
- **syscall** (bool) – True to create the function as a syscall, False otherwise.
- **plt** (bool | None) – True to find the PLT stub, False to find a non-PLT stub, None to disable this restriction.
- **check_previous_names** (*bool*)

**Returns**
The Function instance, or None if the function is not found and create is False.

**Return type**
*Function* | None

**dbg_draw**(*prefix='dbg_function_'*)

**rebuild_callgraph**()

**set_function_returning**(*addr*, *v*)

**Return type**
None

**Parameters**

- **addr** (*K*)
- **v** (*bool | None*)

**nonreturning_func_addrs**()

Yield all non-returning function addresses.

**Return type**
Generator[int]

unknown_returning_func_addrs()

Yield all function addresses with unknown returning status.

**Return type**
Generator[int]

is_func_nonreturning(*addr*)

Check if a function is non-returning.

**Parameters**
**addr** (K) – Address of the function.

**Return type**
bool

**Returns**
True if non-returning, False if returning or unknown.

is_func_returning_unknown(*addr*)

Check if a function's returning status is unknown.

**Parameters**
**addr** (K) – Address of the function.

**Return type**
bool

**Returns**
True if returning status is unknown, False otherwise.

get_func_block_count(*addr*)

Get the number of blocks in a function.

**Parameters**
**addr** (K) – Address of the function.

**Return type**
int | None

**Returns**
Number of blocks, or None if unknown.

set_func_block_count(*addr*, *count*)

Set the number of blocks in a function.

**Parameters**

- **addr** (K) – Address of the function.
- **count** (int) – Number of blocks.

**Return type**
None

**Returns**
None

get_func_addr_with_block_count(*block_count*)

Get the addresses of all functions that have exactly block_count blocks.

**Parameters**
**block_count** (int) – The number of blocks to match.

**Return type**
set[K]

**Returns**
The set of matching function addresses.

`get_func_name`(*addr*)

Get the name of a function without loading the (possibly spilled) Function object.

**Parameters**
**addr** (K) – Address of the function.

**Return type**
str | None

**Returns**
The function's name, or None if unknown.

`get_from_signature`(*addr*)

Get the `from_signature` value of a function without loading the (possibly spilled) Function object.

**Parameters**
**addr** (K) – Address of the function.

**Return type**
str | None

**Returns**
The function's `from_signature` value (e.g. `"flirt"`), or None.

`set_from_signature`(*addr*, *from_signature*)

Update the cached `from_signature` value for a function. Called by Function.from_signature's setter.

**Parameters**

- **addr** (K) – Address of the function.
- **from_signature** (str | None) – The new `from_signature` value.

**Return type**
None

**Returns**
None

`get_all_funcaddrs_from_signature`(*from_signature='flirt'*)

Get the addresses of all functions whose `from_signature` matches, without loading any Function object.

**Parameters**
**from_signature** (str) – The `from_signature` value to match (default `"flirt"`).

**Return type**
set[K]

**Returns**
The set of matching function addresses.

`get_key_func_addrs`(*func_type*)

**Return type**
set[K]

**Parameters**
**func_type** (str)

**get_key_func_type_and_addrs**()

Get all cached key functions grouped by key-function type (e.g. "alloca_probe", "jmp_rax").

**Return type**
dict[str, set[K]]

**Returns**
A mapping from key-function type to the set of function addresses of that type.

**add_key_func_addr**(*func_type*, *addr*)

**Return type**
None

**Parameters**

- **func_type** (*str*)
- **addr** (*K*)

**index_key_func_addrs**(*func*)

Record every key-function flag that func.info carries in the key-function address cache.

**Return type**
None

**Parameters**
**func** (Function)

**property cache_limit: int | None**

Get the maximum number of functions to keep in memory. None means unlimited (no eviction).

**Setter accepts**
int

**property cached_function_count: int**

Return the number of functions currently in memory.

**property spilled_function_count: int**

Return the number of functions currently spilled to LMDB.

**property total_function_count: int**

Return the total number of functions (in memory + spilled).

**class** angr.knowledge_plugins.**IndirectJumps**

Bases: *KnowledgeBasePlugin*, dict

This plugin tracks the targets of indirect jumps

**update_resolved_addrs**(*indirect_address*, *resolved_addresses*)

**Parameters**

- **indirect_address** (*int*)
- **resolved_addresses** (*list[int]*)

**class** angr.knowledge_plugins.**KeyDefinitionManager**

Bases: *KnowledgeBasePlugin*

KeyDefinitionManager manages and caches reaching definition models for each function.

For each function, by default we cache the entire reaching definitions model with observed results at the following locations: - Before each call instruction: ('insn', address of the call instruction, OP_BEFORE) - After returning from each call: ('node', address of the block that ends with a call, OP_AFTER)

**__init__**(*kb*)

**Parameters**
**kb** (KnowledgeBase)

**has_model**(*func_addr*)

**Parameters**
**func_addr** (*int*)

**get_model**(*func_addr*)

**Parameters**
**func_addr** (*int*)

**copy**()

**Return type**
*KeyDefinitionManager*

**class** angr.knowledge_plugins.**KnowledgeBasePlugin**

Bases: object

**__init__**(*kb*)

**Parameters**
**kb** (KnowledgeBase)

**copy**()

**set_kb**(*kb*)

Invoked after __setstate__() is called.

**Parameters**
**kb** (KnowledgeBase)

**static register_default**(*name*, *cls*)

**class** angr.knowledge_plugins.**Labels**

Bases: *KnowledgeBasePlugin*

**__init__**(*kb*)

**items**()

**get**(*addr*, *default=None*)

Get a label as string for a given address Same as .labels[x]

**lookup**(*name*, *default=None*)

Returns an address to a given label To show all available labels, iterate over .labels or list(b.kb.labels)

**copy**()

**get_unique_label**(*label*)

Get a unique label name from the given label name.

**Parameters**
**label** (*str*) – The desired label name.

**Returns**
A unique label name.

class angr.knowledge_plugins.**Obfuscations**

Bases: *KnowledgeBasePlugin*

Store discovered information and artifacts about (string) obfuscation techniques in the project.

**__init__**(*kb*)

**copy**()

class angr.knowledge_plugins.**PatchManager**

Bases: *KnowledgeBasePlugin*

A placeholder-style implementation for a binary patch manager. This class should be significantly changed in the future when all data about loaded binary objects are loaded into angr knowledge base from CLE. As of now, it only stores byte-level replacements.

Patches should not overlap, but it's user's responsibility to check for and avoid overlapping patches.

**__init__**(*kb*)

**has_patches**()

**Return type**
bool

**add_patch**(*addr*, *new_bytes*, *comment=None*)

**Parameters**
**comment** (*str | None*)

**add_patch_obj**(*patch*)

**Parameters**
**patch** (Patch)

**remove_patch**(*addr*)

**patch_addrs**()

**get_patch**(*addr*)

Get patch at the given address.

**Parameters**
**addr** (*int*) – The address of the patch.

**Returns**
The patch if there is one starting at the address, or None if there isn't any.

**Return type**
*Patch* or None

**get_all_patches**(*addr*, *size*)

Retrieve all patches that cover a region specified by [addr, addr+size).

**Parameters**

- **addr** (*int*) – The address of the beginning of the region.
- **size** (*int*) – Size of the region.

**Returns**
A list of patches.

**Return type**
list

**keys**()

**items**()

**values**()

**copy**()

**static overlap**(*a0*, *a1*, *b0*, *b1*)

**apply_patches_to_binary**(*binary_bytes=None*, *patches=None*)

**Return type**
bytes

**Parameters**

- **binary_bytes** (bytes | *None*)
- **patches** (*list[Patch]* | *None*)

**apply_patches_to_state**(*state*)

**property patched_entry_state**

**class** angr.knowledge_plugins.**Patterns**

Bases: *KnowledgeBasePlugin*

The fuzzy patterns of a knowledge base, by pattern name.

**__init__**(*kb*)

**Parameters**
**kb** (KnowledgeBase)

**copy**()

**Return type**
*Patterns*

**record_stats**(*func_addr*, *stats*)

Replace what is known about `func_addr`: the outliner pass saw exactly these patterns.

**Return type**
None

**Parameters**

- **func_addr** (*int*)
- **stats** (*dict[str, PatternStats]*)

**stats**(*func_addr*, *name*)

The outliner pass's numbers for a pattern in a function, or None if it did not search for that pattern there when it last ran.

**Return type**
*PatternStats* | None

**Parameters**

- **func_addr** (*int*)
- **name** (*str*)

**get**(*name*)

**Return type**
*StoredPattern* | None

**Parameters**
**name** (*str*)

**add**(*pattern*, ***, *enabled=True*, *min_similarity=0.8*, *origin_func=None*, *require_verified=True*, *replace=False*)
Store `pattern`. Refuses a name or call name already taken unless `replace`.

**Return type**
*StoredPattern*

**Parameters**

- **pattern** (KnownPattern)
- **enabled** (*bool*)
- **min_similarity** (*float*)
- **origin_func** (*int | None*)
- **require_verified** (*bool*)
- **replace** (*bool*)

**store**(*stored*)
Put a StoredPattern back, keeping its settings (a loader's entry point).

**Return type**
None

**Parameters**
**stored** (StoredPattern)

**remove**(*name*)

**Return type**
bool

**Parameters**
**name** (*str*)

**set_enabled**(*name*, *enabled*)

**Return type**
None

**Parameters**

- **name** (*str*)
- **enabled** (*bool*)

**enabled_patterns**()

**Return type**
list[*StoredPattern*]

**by_call_name**(*call_name*)

**Return type**
*StoredPattern* | None

**Parameters**
**call_name** (*str*)

**to_records**()

**Return type**
list[dict[str, Any]]

**load_records**(*records*)

**Return type**
None

**Parameters**
**records** (*list[dict[str, Any]]*)

**class** angr.knowledge_plugins.**PropagationManager**

Bases: *KnowledgeBasePlugin*

Manages the results of Propagator, including intermediate results for unfinished Propagation runs.

**__init__**(*kb*)

**exists**(*prop_key*)

Internal function to check if a func, specified as a CodeLocation exists in our known propagations

**Parameters**
**prop_key** (tuple) – A key of the propagation result.

**Return type**
bool

**Returns**
Whether such a key exists or not.

**update**(*prop_key*, *model*)

Add the replacements to known propagations

**Parameters**

- **prop_key** (tuple) – A key of the propagation result.
- **model** (*PropagationModel*) – The propagation result to store

**Return type**
None

**get**(*prop_key*, *default=None*)

Gets the replacements for a specified function location. If the replacement does not exist in the known propagations, it returns None.

**Parameters**

- **prop_key** – A key of the propagation result.
- **default** – The default value to return if the prop_key does not exist in the cache.

**Return type**
*PropagationModel*

**Returns**
Dict or None

`copy()`

`discard_by_prefix(prefix)`

**Parameters**
**prefix** (*str*)

`class angr.knowledge_plugins.RuntimeDb`

Bases: *KnowledgeBasePlugin*

External storage-backed database for angr knowledge base plugins.

`__init__(kb, lmdb_path=None)`

**Parameters**

- **kb** (KnowledgeBase)
- **lmdb_path** (*str | None*)

**Return type**
None

`increase_lmdb_map_size()`

Increase the LMDB map size. Returns False when there is no environment to grow (callers must not retry).

Note that the old database handle *may* no longer be valid after a map size increase. rhelmot could reproduce the error "Database handle belongs to another environment." in nix + CPython 3.13.13. Reopening all databases after increasing LMDB map size solves this issue.

**Return type**
bool

`reopen_lmdb()`

Reopen the existing LMDB environment and all open databases in self._dbs.

`reopen_lmdb_databases()`

`open_db(db_name, unique=True)`

**Return type**
str

**Parameters**

- **db_name** (*str*)
- **unique** (*bool*)

`begin_txn(db_name, write=False)`

**Parameters**

- **db_name** (*str*)
- **write** (*bool*)

`drop_db(db_name)`

**Return type**
None

**Parameters**
**db_name** (*str*)

**cleanup**()

Close the LMDB environment and remove the rtdb directory if this is the last user of it. This method may be invoked multiple times (e.g., once by the atexit hook and once more by __del__) and should not fail.

**class** angr.knowledge_plugins.**StoredPattern**

Bases: object

One fuzzy pattern and its application settings.

**pattern:** *KnownPattern*

**enabled:** bool = True

**min_similarity:** float = 0.8

an occurrence is outlined only at this similarity or above (see search.TemplateMatch)

**origin_func:** int | None = None

address of the function the pattern was lifted from, if any

**require_verified:** bool = True

outline only occurrences that pass the pattern's structural match (constants, captures); off, similarity alone decides, as it does for discovered patterns

**created_at:** float

**property name:** str

**to_dict**()

**Return type**
dict[str, Any]

**classmethod from_dict**(*data*)

**Return type**
*StoredPattern*

**Parameters**
**data** (*dict[str, Any]*)

**__init__**(*pattern*, *enabled=True*, *min_similarity=0.8*, *origin_func=None*, *require_verified=True*, *created_at=<factory>*)

**Parameters**

- **pattern** (KnownPattern)
- **enabled** (*bool*)
- **min_similarity** (*float*)
- **origin_func** (*int | None*)
- **require_verified** (*bool*)
- **created_at** (*float*)

**Return type**
None

class angr.knowledge_plugins.**StructuredCodeManager**

Bases: *KnowledgeBasePlugin*

A knowledge base plugin to store structured code generator results.

**__init__**(*kb*, *cache_limit=None*)

**Parameters**
**cache_limit** (*int | None*)

**get**(*key*, *default=None*)

**discard**(*key*)

**available_flavors**(*item*)

**all_flavors**(*item*)

**copy**()

class angr.knowledge_plugins.**TypesStore**

Bases: *KnowledgeBasePlugin*, UserDict[str, *TypeRef*]

A kb plugin that stores a mapping from name to TypeRef. It will return types from angr.sim_type.ALL_TYPES as a default.

**__init__**(*kb*)

**copy**(*kb=None*)

Copy the store's own entries (not ALL_TYPES) into a new store for kb (default: the same knowledge base). Each entry gets a new TypeRef pointing at the same target type.

**Return type**
*TypesStore*

**Parameters**
**kb** (KnowledgeBase | *None*)

**get_own**(*item*)

**Return type**
*TypeRef*

**Parameters**
**item** (*str*)

**iter_own**()

Iterate over all the names which are stored in this object - i.e. values() without ALL_TYPES

**iter_own_keys**()

**rename**(*old*, *new*)

**Parameters**

- **old** (*str*)
- **new** (*str*)

**unique_type_name**()

**Return type**
str

class angr.knowledge_plugins.**VariableManager**

Bases: *KnowledgeBasePlugin*

Manage variables.

**__init__**(*kb*)

**global_managers:** dict[str, *VariableManagerInternal*]

**function_managers:** dict[int, *VariableManagerInternal*] | *SpillingVariableInternalDict*

**property global_manager:** *VariableManagerInternal*

The global manager of the default flavor. Code with no decompilation flavor (CFG, DWARF, SimProcedures) uses it.

**get_global_manager**(*flavor*)

The global manager that a decompilation of the given flavor (None means the default flavor) reads and writes. A new flavor starts empty: global names are re-derived from labels, types are re-inferred.

**Return type**
*VariableManagerInternal*

**Parameters**
**flavor** (*str | None*)

**set_global_manager**(*flavor*, *manager*)

**Return type**
None

**Parameters**

- **flavor** (*str | None*)
- **manager** (VariableManagerInternal)

**has_function_manager**(*key*)

**Return type**
bool

**Parameters**
**key** (*int*)

**has_function_manager_for_flavor**(*key*, *flavor*)

Whether a function manager exists and can be reused by a decompilation of the given flavor. A manager of unknown flavor (None) is compatible with any flavor.

**Return type**
bool

**Parameters**

- **key** (*int*)
- **flavor** (*str*)

**get_function_manager**(*func_addr*)

**Return type**
*VariableManagerInternal*

**initialize_variable_names**()

**Return type**
None

**get_variable_accesses**(*variable*, *same_name=False*)

Get a list of all references to the given variable.

**Parameters**

- **variable** (*SimVariable*) – The variable.
- **same_name** (bool) – Whether to include all variables with the same variable name, or just based on the variable identifier.

**Return type**
list[*VariableAccess*]

**Returns**
All references to the variable.

**copy**()

**Return type**
*VariableManager*

**static convert_variable_list**(*vlist*, *manager*)

**Parameters**

- **vlist** (*list[Variable]*)
- **manager** (VariableManagerInternal)

**load_from_dwarf**(*cu_list=None*)

**Parameters**
**cu_list** (*list[CompilationUnit] | None*)

**class** angr.knowledge_plugins.**XRefManager**

Bases: *KnowledgeBasePlugin*, *Serializable*

**__init__**(*kb*)

**copy**()

**clear**()

**add_xref**(*xref*)

**add_xrefs**(*xrefs*)

**get_xrefs_by_ins_addr**(*ins_addr*)

**get_xrefs_by_dst**(*dst*)

**get_xrefs_by_dst_region**(*start*, *end*)

Get a set of XRef objects that point to a given address region bounded by start and end. Will only return absolute xrefs, not relative ones (like SP offsets)

**get_next_xref_addr_by_dst**(*addr*)

Get the next XRef object whose address is greater than or equal to the given address. Will only return absolute xrefs, not relative ones (like SP offsets)

**Return type**
int | None

**Parameters**
**addr** (*int*)

**get_xrefs_by_ins_addr_region**(*start*, *end*)

Get a set of XRef objects that originate at a given address region bounded by start and end. Useful for finding references from a basic block or function.

**Return type**
set[*XRef*]

## 10.24.1 angr.knowledge_plugins.bookmarks

**class** angr.knowledge_plugins.bookmarks.**Bookmark**

Bases: object

A user-marked address with an optional label.

**__init__**(*addr*, *label=''*, *created_at=None*)

**Parameters**

- **addr** (*int*)
- **label** (*str*)

- **created_at** (*float | None*)

**Return type**
None

**addr**

**label**

**created_at**

class angr.knowledge_plugins.bookmarks.**Bookmarks**

Bases: *KnowledgeBasePlugin*, list

Tracks bookmarks as a list of *Bookmark*, in creation order.

**get_bookmark**(*addr*)

**Return type**
*Bookmark* | None

**Parameters**
**addr** (*int*)

**has_bookmark**(*addr*)

**Return type**
bool

**Parameters**
**addr** (*int*)

**add_bookmark**(*addr*, *label=''*)

Bookmark addr, or relabel the bookmark already there if label is non-empty. Returns the bookmark and whether it was newly created.

**Return type**
tuple[*Bookmark*, bool]

**Parameters**

- **addr** (*int*)
- **label** (*str*)

**remove_bookmark**(*bookmark*)

Remove bookmark if present. Returns whether it was removed.

**Return type**
bool

**Parameters**
**bookmark** (Bookmark)

**toggle_bookmark**(*addr*, *label=''*)

Add a bookmark at addr, or remove the one already there. Returns the new one, if any.

**Return type**
*Bookmark* | None

**Parameters**

- **addr** (*int*)

- **label** (*str*)

**sorted_bookmarks**()

**Return type**
list[*Bookmark*]

**next_bookmark**(*after_addr*)

The next bookmark by address, wrapping around.

**Return type**
*Bookmark* | None

**Parameters**
**after_addr** (*int | None*)

### 10.24.2 angr.knowledge_plugins.callsite_prototypes

**class** angr.knowledge_plugins.callsite_prototypes.**CallsitePrototypeKind**

Bases: Enum

Describes the type of a callsite prototype.

**INFERRED = 1**

**PROPAGATED = 2**

**MANUAL = 3**

**class** angr.knowledge_plugins.callsite_prototypes.**CallsitePrototypes**

Bases: *KnowledgeBasePlugin*

CallsitePrototypes manages callee prototypes at call sites, per decompilation flavor. Every method takes a flavor (None: the default flavor). A non-default flavor reads its own entry of a kind at a call site, or the default flavor's entry of that kind when it has none, like Function.get_prototype().

**__init__**(*kb*)

**property flavors: list[str]**

The flavors that have entries of their own.

**set_prototype**(*callsite_block_addr*, *cc*, *prototype*, ***, *kind=CallsitePrototypeKind.INFERRED*, *manual=False*, *propagated=False*, *flavor=None*)

**Return type**
None

**Parameters**

- **callsite_block_addr** (*int*)
- **cc** (SimCC)
- **prototype** (SimTypeFunction)
- **kind** (CallsitePrototypeKind)
- **manual** (*bool*)
- **propagated** (*bool*)
- **flavor** (*str | None*)

**remove_prototype**(*callsite_block_addr*, *, *kind=CallsitePrototypeKind.INFERRED*, *flavor=None*)

Remove the flavor's own entry of a kind; a non-default flavor then falls back to the default one.

**Return type**
None

**Parameters**

- **callsite_block_addr** (*int*)
- **kind** (CallsitePrototypeKind)
- **flavor** (*str | None*)

**get_cc**(*callsite_block_addr*, *, *kind=CallsitePrototypeKind.INFERRED*, *flavor=None*)

**Return type**
*SimCC* | None

**Parameters**

- **callsite_block_addr** (*int*)
- **kind** (CallsitePrototypeKind)
- **flavor** (*str | None*)

**get_prototype**(*callsite_block_addr*, *, *kind=CallsitePrototypeKind.INFERRED*, *flavor=None*)

**Return type**
*SimTypeFunction* | None

**Parameters**

- **callsite_block_addr** (*int*)
- **kind** (CallsitePrototypeKind)
- **flavor** (*str | None*)

**is_prototype_manual**(*callsite_block_addr*, *, *flavor=None*)

**Return type**
bool | None

**Parameters**

- **callsite_block_addr** (*int*)
- **flavor** (*str | None*)

**is_prototype_certain**(*callsite_block_addr*, *, *flavor=None*)

**Return type**
bool | None

**Parameters**

- **callsite_block_addr** (*int*)
- **flavor** (*str | None*)

**has_some_prototype**(*callsite_block_addr*, *, *flavor=None*)

**Return type**
bool

**Parameters**

- **callsite_block_addr** (*int*)
- **flavor** (*str | None*)

**has_prototype**(*callsite_block_addr*, ***, *kind=CallsitePrototypeKind.INFERRED*, *flavor=None*)

**Return type**
bool

**Parameters**

- **callsite_block_addr** (*int*)
- **kind** (CallsitePrototypeKind)
- **flavor** (*str | None*)

**has_prototype_for_flavor**(*callsite_block_addr*, ***, *kind=CallsitePrototypeKind.INFERRED*, *flavor=None*)

Whether the flavor has its own entry of the kind (as opposed to falling back to the default flavor's).

**Return type**
bool

**Parameters**

- **callsite_block_addr** (*int*)
- **kind** (CallsitePrototypeKind)
- **flavor** (*str | None*)

**items**(*flavor=None*)

The flavor's own entries (no fallback).

**Return type**
Iterator[tuple[int, *CallsitePrototypeKind*, *SimCC*, *SimTypeFunction*]]

**Parameters**
**flavor** (*str | None*)

**copy**()

### 10.24.3 angr.knowledge_plugins.cfg

**class** angr.knowledge_plugins.cfg.**BlockID**

Bases: object

A context-sensitive key for a SimRun object.

**__init__**(*addr*, *callsite_tuples*, *jump_type*)

**Parameters**

- **addr** (*int*)
- **callsite_tuples** (*tuple[int, ...] | None*)
- **jump_type** (*str*)

**callsite_repr**()

**static new**(*addr*, *callstack_suffix*, *jumpkind*)

property func_addr

class angr.knowledge_plugins.cfg.CFGENode

Bases: *CFGNode*

The CFGNode that is used in CFGEmulated.

input_state

looping_times

depth

creation_failure_info

final_states

syscall

return_target

property callstack_key

property creation_failed

property syscall_name: str | None

downsize()

Drop saved states.

copy()

class angr.knowledge_plugins.cfg.CFGManager

Bases: *KnowledgeBasePlugin*

This is the CFG manager, it manages CFGs

__init__(*kb*)

new_model(*prefix*, *addr_type='int'*)

**Parameters**
**addr_type** (*CFG_ADDR_TYPES*)

copy()

get_most_accurate()

**Return type**
*CFGModel* | None

**Returns**
The most accurate CFG present in the CFGManager, or None if it does not hold any.

class angr.knowledge_plugins.cfg.CFGModel

Bases: *Serializable*

This class describes a Control Flow Graph for a specific range of code.

__init__(*ident*, *cfg_manager=None*, *is_arm=False*, *cache_limit=None*, *db_batch_size=800*, *addr_type='int'*, *segment_budget=None*)

**Parameters**

- **cache_limit** (*int | None*)
- **db_batch_size** (*int*)
- **addr_type** (*CFG_ADDR_TYPES*)
- **segment_budget** (*int | None*)

**ident**

**is_arm**

**graph:** *SpillingCFG*

**jump_tables:** dict[int, *IndirectJump*]

**memory_data:** SortedDict[int, *MemoryData*]

**insn_addr_to_memory_data:** dict[int, *MemoryData*]

**normalized**

**edges_to_repair**

**property addr_type:** Literal['int', 'block_id', 'soot']

**property project**

**property node_addrs:** SortedList[int]

**nodes_by_addr**(*addr*)

**Return type**
Iterator[*CFGNode*]

**Parameters**
**addr** (*int*)

**has_node_addr**(*addr*)

**Return type**
bool

**Parameters**
**addr** (*int*)

**mark_node_addr_has_return**(*node_addr*, *has_return=True*)

**Return type**
None

**Parameters**

- **node_addr** (*int | SootAddressDescriptor*)
- **has_return** (*bool*)

**node_addr_has_return**(*node_addr*)

**Return type**
bool

**Parameters**
**node_addr** (*int | SootAddressDescriptor*)

**copy**()

**add_node**(*block_id*, *node*)

**Return type**
None

**Parameters**

- **block_id** (*int*)
- **node** (CFGNode)

**remove_node**(*block_id*, *node*)

Remove the given CFGNode instance. Note that this method *does not* remove the node from the graph.

**Parameters**

- **block_id** (int) – The Unique ID of the CFGNode.
- **node** (*CFGNode*) – The CFGNode instance to remove.

**Return type**
None

**Returns**
None

**has_node_id**(*node_id*)

**Return type**
bool

**get_node**(*block_id*)

Get a single node from Block ID.

**Parameters**
**block_id** (BlockID) – Block ID of the node.

**Return type**
*CFGNode* | None

**Returns**
The CFGNode, or None if the node does not exist.

**get_any_node**(*addr*, *is_syscall=None*, *anyaddr=False*, *force_fastpath=False*)

Get an arbitrary CFGNode (without considering their contexts) from our graph.

**Parameters**

- **addr** (int) – Address of the beginning of the basic block. Set anyaddr to True to support arbitrary address.
- **is_syscall** (bool | None) – Whether you want to get the syscall node or any other node. This is due to the fact that syscall SimProcedures have the same address as the target it returns to. None means get either, True means get a syscall node, False means get something that isn't a syscall node.

- **anyaddr** (bool) – If anyaddr is True, then addr doesn't have to be the beginning address of a basic block. By default the entire graph.nodes() will be iterated, and the first node containing the specific address is returned, which can be slow.
- **force_fastpath** (bool) – If force_fastpath is True, it will only perform a dict lookup in the graph._keys_by_addr dict.

**Return type**
*CFGNode* | None

**Returns**
A CFGNode if there is any that satisfies given conditions, or None otherwise

**get_all_nodes**(*addr*, *is_syscall=None*, *anyaddr=False*)

Get all CFGNodes whose address is the specified one.

**Parameters**

- **addr** (int) – Address of the node
- **is_syscall** (bool | None) – True returns the syscall node, False returns the normal CFGNode, None returns both
- **anyaddr** (*bool*)

**Return type**
list[*CFGNode*]

**Returns**
all CFGNodes

**get_all_nodes_intersecting_region**(*addr*, *size=1*)

Get all CFGNodes that intersect the given region.

**Parameters**

- **addr** (int) – Minimum address of target region.
- **size** (int) – Size of region, in bytes.

**Return type**
set[*CFGNode*]

**floor_addr**(*addr*)

Get the largest address that is less than or equal to the given address and has a CFGNode.

**Parameters**
**addr** (int) – The address to floor.

**Return type**
int | None

**Returns**
The largest address that is less than or equal to the given address and has a CFGNode, or None if no such address exists.

**ceil_addr**(*addr*)

Get the smallest address that is greater than or equal to the given address and has a CFGNode.

**Parameters**
**addr** (int) – The address to ceil.

**Return type**
int | None

**Returns**
The smallest address that is greater than or equal to the given address and has a CFGNode, or None if no such address exists.

**nodes**()

An iterator of all nodes in the graph.

**Returns**
The iterator.

**Return type**
iterator

**get_predecessors**(*cfgnode*, *excluding_fakeret=True*, *jumpkind=None*)

Get predecessors of a node in the control flow graph.

**Parameters**

- **cfgnode** (*CFGNode*) – The node.
- **excluding_fakeret** (bool) – True if you want to exclude all predecessors that is connected to the node with a fakeret edge.
- **jumpkind** (str | None) – Only return predecessors with the specified jumpkind. This argument will be ignored if set to None.

**Return type**
list[*CFGNode*]

**Returns**
A list of predecessors

**get_successors**(*node*, *excluding_fakeret=True*, *jumpkind=None*)

Get successors of a node in the control flow graph.

**Parameters**

- **node** (*CFGNode*) – The node.
- **excluding_fakeret** (bool) – True if you want to exclude all successors that is connected to the node with a fakeret edge.
- **jumpkind** (str | None) – Only return successors with the specified jumpkind. This argument will be ignored if set to None.

**Returns**
A list of successors

**Return type**
list[*CFGNode*]

**get_successors_and_jumpkinds**(*node*, *excluding_fakeret=True*)

Get a list of tuples where the first element is the successor of the CFG node and the second element is the jumpkind of the successor.

**Parameters**

- **node** (CFGNode) – The node.
- **excluding_fakeret** (*bool*) – True if you want to exclude all successors that are fall-through successors.

**Returns**
A list of successors and their corresponding jumpkinds.

**Return type**
list[tuple[*CFGNode*, str]]

**get_successors_and_jumpkind**(*node*, *excluding_fakeret=True*)

Get a list of tuples where the first element is the successor of the CFG node and the second element is the jumpkind of the successor.

**Parameters**

- **node** (CFGNode) – The node.
- **excluding_fakeret** (*bool*) – True if you want to exclude all successors that are fall-through successors.

**Returns**
A list of successors and their corresponding jumpkinds.

**Return type**
list[tuple[*CFGNode*, str]]

**get_predecessors_and_jumpkinds**(*node*, *excluding_fakeret=True*)

Get a list of tuples where the first element is the predecessor of the CFG node and the second element is the jumpkind of the predecessor.

**Parameters**

- **node** (*CFGNode*) – The node.
- **excluding_fakeret** (bool) – True if you want to exclude all predecessors that are fall-through predecessors.

**Return type**
list[tuple[*CFGNode*, str]]

**Returns**
A list of predecessors and their corresponding jumpkinds.

**get_predecessors_and_jumpkind**(*node*, *excluding_fakeret=True*)

Get a list of tuples where the first element is the predecessor of the CFG node and the second element is the jumpkind of the predecessor.

**Parameters**

- **node** (*CFGNode*) – The node.
- **excluding_fakeret** (bool) – True if you want to exclude all predecessors that are fall-through predecessors.

**Return type**
list[tuple[*CFGNode*, str]]

**Returns**
A list of predecessors and their corresponding jumpkinds.

**get_all_predecessors**(*cfgnode*, *depth_limit=None*)

Get all predecessors of a specific node on the control flow graph.

**Parameters**

- **cfgnode** (CFGNode) – The CFGNode object
- **depth_limit** (*int*) – Optional depth limit for the depth-first search

**Returns**
A list of predecessors in the CFG

**Return type**
list

`get_all_successors`(*cfgnode*, *depth_limit=None*)

Get all successors of a specific node on the control flow graph.

**Parameters**

- **cfgnode** (CFGNode) – The CFGNode object
- **depth_limit** (*int*) – Optional depth limit for the depth-first search

**Returns**
A list of successors in the CFG

**Return type**
list

`get_branching_nodes`()

Returns all nodes that has an out degree >= 2

`get_exit_stmt_idx`(*src_block*, *dst_block*)

Get the corresponding exit statement ID for control flow to reach destination block from source block. The exit statement ID was put on the edge when creating the CFG. Note that there must be a direct edge between the two blocks, otherwise an exception will be raised.

**Returns**
The exit statement ID

`add_memory_data`(*data_addr*, *data_type*, *data_size=None*)

Add a MemoryData entry to self.memory_data.

**Parameters**

- **data_addr** (int) – Address of the data
- **data_type** (*MemoryDataSort* | None) – Type of the memory data
- **data_size** (int | None) – Size of the memory data, or None if unknown for now.

**Return type**
bool

**Returns**
True if a new memory data entry is added, False otherwise.

`tidy_data_references`(*memory_data_addrs=None*, *exec_mem_regions=None*, *xrefs=None*, *seg_list=None*, *data_type_guessing_handlers=None*, *fill_gaps=True*, *new_mem_data_addrs=None*)

Go through all data references (or the ones as specified by memory_data_addrs) and determine their sizes and types if possible.

**Parameters**

- **memory_data_addrs** (list[int] | None) – A list of addresses of memory data, or None if tidying all known memory data entries.
- **exec_mem_regions** (list[tuple[int, int]] | None) – A list of start and end addresses of executable memory regions.
- **seg_list** (SegmentList | None) – The segment list that CFGFast uses during CFG recovery.

- **data_type_guessing_handlers** (list[Callable] | None) – A list of Python functions that will guess data types. They will be called in sequence to determine data types for memory data whose type is unknown.
- **fill_gaps** (bool) – If True, when a memory data entry is found to have a gap between its end and the next data entry, a new memory data entry will be created to fill the gap. fill_gaps should only be set to True at the end of CFG recovery when traversing the entire memory_data dict for the last time.
- **xrefs** (*XRefManager | None*)
- **new_mem_data_addrs** (*set[int] | None*)

**Return type**
bool

**Returns**
True if new data entries are found, False otherwise.

**remove_node_and_graph_node**(*node*)

Like *remove_node*, but also removes node from the graph.

**Parameters**
**node** (*CFGNode*) – The node to remove.

**Return type**
None

**get_intersecting_functions**(*addr*, *size=1*, *kb=None*)

Find all functions with nodes intersecting [addr, addr + size).

**Parameters**

- **addr** (int) – Minimum address of target region.
- **size** (int) – Size of region, in bytes.
- **kb** (*KnowledgeBase* | None) – Knowledge base to search for functions in.

**Return type**
set[*Function*]

**find_function_for_reflow_into_addr**(*addr*, *kb=None*)

Look for a function that flows into a new node at addr.

**Parameters**

- **addr** (int) – Address of new block.
- **kb** (*KnowledgeBase* | None) – Knowledge base to search for functions in.

**Return type**
*Function* | None

**clear_region_for_reflow**(*addr*, *size=1*, *kb=None*)

Remove nodes in the graph intersecting region [addr, addr + size).

Any functions that intersect the range, and their associated nodes in the CFG, will also be removed from the knowledge base for analysis.

**Parameters**

- **addr** (int) – Minimum address of target region.
- **size** (int) – Size of the region, in bytes.

- **kb** (*KnowledgeBase* | None) – Knowledge base to search for functions in.

**Return type**
None

class angr.knowledge_plugins.cfg.**CFGNode**

Bases: *Serializable*

This class stands for each single node in CFG.

**__init__**(*addr*, *size*, *cfg*, *simprocedure_name=None*, *no_ret=False*, *function_address=None*, *block_id=None*, *irsb=None*, *soot_block=None*, *instruction_addrs=None*, *thumb=False*, *byte_string=None*, *is_syscall=None*, *name=None*)

Note: simprocedure_name is not used to recreate the SimProcedure object. It's only there for better __repr__.

**Parameters**
**block_id** (*BlockID* | *int* | *None*)

**simprocedure_name**

**instruction_addrs**

**irsb**

**soot_block**

**property dirty**

**Setter accepts**
bool

**property function_address**

**property addr**

**property block_id**

**property byte_string: bytes | None**

**property is_syscall: bool**

**property thumb: bool**

**property size: int**

**property no_ret: bool**

**property name**

**property successors**

**property predecessors**

**successors_and_jumpkinds**(*excluding_fakeret=True*)

**predecessors_and_jumpkinds**(*excluding_fakeret=True*)

**get_data_references**(*kb=None*)

Get the known data references for this CFGNode via the knowledge base.

**Parameters**
**kb** – Which knowledge base to use; uses the global KB by default if none is provided

**Returns**
Generator yielding xrefs to this CFGNode's block.

**Return type**
iter

**property accessed_data_references**

Property providing a view of all the known data references for this CFGNode via the global knowledge base

**Returns**
Generator yielding xrefs to this CFGNode's block.

**Return type**
iter

**property is_simprocedure**

**property callstack_key**

**copy**()

**merge**(*other*)

Merges this node with the other, returning a new node that spans the both.

**to_codenode**()

**property block:** *Block* | *SootBlock* | None

**class** angr.knowledge_plugins.cfg.**IndirectJump**

Bases: *Serializable*

Describes an indirect jump or call site.

**__init__**(*addr*, *ins_addr*, *func_addr*, *jumpkind*, *stmt_idx*, *resolved_targets=None*, *jumptable=False*, *jumptable_addr=None*, *jumptable_size=None*, *jumptable_entry_size=None*, *jumptable_entries=None*, *jumptable_entries_guessed=False*, *type_=255*)

**Parameters**

- **addr** (*int*)
- **ins_addr** (*int*)
- **func_addr** (*int*)
- **jumpkind** (*str*)
- **stmt_idx** (*int*)
- **resolved_targets** (*list[int] | None*)
- **jumptable** (*bool*)
- **jumptable_addr** (*int | None*)
- **jumptable_size** (*int | None*)
- **jumptable_entry_size** (*int | None*)

- **jumptable_entries** (*list[int] | None*)
- **jumptable_entries_guessed** (*bool*)
- **type_** (*int | None*)

**addr**

**ins_addr**

**func_addr**

**jumpkind**

**stmt_idx**

**resolved_targets**

**jumptable**

**jumptables:** list[*JumptableInfo*]

**type**

**add_jumptable**(*addr*, *size*, *entry_size*, *entries*, *is_primary=False*, ***, *entries_guessed=False*)

**Return type**
None

**Parameters**

- **addr** (*int | None*)
- **size** (*int*)
- **entry_size** (*int*)
- **entries** (*list[int]*)
- **is_primary** (*bool*)
- **entries_guessed** (*bool*)

**property jumptable_addr:** int | None

**property jumptable_size:** int | None

**property jumptable_entry_size:** int | None

**property jumptable_entries:** list[int] | None

**property jumptable_entries_guessed:** bool | None

**class** angr.knowledge_plugins.cfg.**IndirectJumpType**

Bases: object

The type of an indirect jump or call.

**Jumptable_AddressLoadedFromMemory = 0**

**Jumptable_AddressComputed = 1**

**Vtable = 3**

**Unknown = 255**

**class** angr.knowledge_plugins.cfg.**MemoryData**

Bases: *Serializable*

MemoryData describes the syntactic content of a single address of memory.

*reference_size* reflects the size of *content*. It can be different from *size*, which is the actual size of the memory data item in memory. The intended way to get the actual content in memory is *self.content[:self.size]*.

**__init__**(*address*, *size*, *sort*, *pointer_addr=None*, *max_size=None*, *reference_size=None*)

**Parameters**

- **address** (*int*)
- **size** (*int*)
- **sort** (*str | None*)
- **pointer_addr** (*int | None*)
- **max_size** (*int | None*)
- **reference_size** (*int | None*)

**addr:** int

**size:** int

**reference_size:** int

**sort:** str | None

**max_size:** int | None

**pointer_addr:** int | None

**content:** bytes | None

**property address**

**copy**()

Make a copy of the MemoryData.

**Returns**
A copy of the MemoryData instance.

**Return type**
*MemoryData*

**fill_content**(*loader*)

Load data to fill self.content.

**Parameters**
**loader** – The project loader.

**Returns**
None

**class** angr.knowledge_plugins.cfg.**MemoryDataSort**

Bases: object

```
Unspecified = None

Unknown = 'unknown'

Integer = 'integer'

PointerArray = 'pointer-array'

String = 'string'

UnicodeString = 'unicode'

SegmentBoundary = 'segment-boundary'

CodeReference = 'code reference'

GOTPLTEntry = 'GOT PLT Entry'

ELFHeader = 'elf-header'

FloatingPoint = 'fp'

Alignment = 'alignment'

PEImportDirectory = 'pe-import-directory'

PEExportDirectory = 'pe-export-directory'

PEDelayImportDirectory = 'pe-delay-import-directory'

EHFuncInfo = 'eh-funcinfo'

EHUnwindMapEntry = 'eh-unwindmapentry'

EH4ScopeTable = 'eh4-scopetable'

EHTryBlockMap = 'eh-tryblockmap'

EHHandlerType = 'eh-handlertype'
```

### Submodules

| *cfg_model* | |
| *cfg_node* | |
| *indirect_jump* | |
| *memory_data* | |
| *spilling_cfg* | CFG graph storage: CFGNode instances live in SpillingCFGNodeDict (LRU caching + LMDB spilling, following the SpillingFunctionDict pattern); the graph structure and edge attributes live in the packed Rust store CfgGraph. |
| *types* | |

### angr.knowledge_plugins.cfg.block_id

**class** angr.knowledge_plugins.cfg.block_id.**BlockID**

Bases: object

A context-sensitive key for a SimRun object.

**__init__**(*addr*, *callsite_tuples*, *jump_type*)

**Parameters**

- **addr** (*int*)
- **callsite_tuples** (*tuple[int, ...] | None*)
- **jump_type** (*str*)

**callsite_repr**()

**static new**(*addr*, *callstack_suffix*, *jumpkind*)

**property func_addr**

### angr.knowledge_plugins.cfg.cfg_manager

**class** angr.knowledge_plugins.cfg.cfg_manager.**CFGManager**

Bases: *KnowledgeBasePlugin*

This is the CFG manager, it manages CFGs

**__init__**(*kb*)

**new_model**(*prefix*, *addr_type='int'*)

**Parameters**
**addr_type** (*CFG_ADDR_TYPES*)

**copy**()

**get_most_accurate**()

**Return type**
*CFGModel* | None

**Returns**
The most accurate CFG present in the CFGManager, or None if it does not hold any.

### angr.knowledge_plugins.cfg.cfg_model

**class** angr.knowledge_plugins.cfg.cfg_model.**CFGModel**

Bases: *Serializable*

This class describes a Control Flow Graph for a specific range of code.

**__init__**(*ident*, *cfg_manager=None*, *is_arm=False*, *cache_limit=None*, *db_batch_size=800*, *addr_type='int'*, *segment_budget=None*)

**Parameters**

- **cache_limit** (*int | None*)
- **db_batch_size** (*int*)
- **addr_type** (*CFG_ADDR_TYPES*)

- **segment_budget** (*int | None*)

**ident**

**is_arm**

**graph:** *SpillingCFG*

**jump_tables:** dict[int, *IndirectJump*]

**memory_data:** SortedDict[int, *MemoryData*]

**insn_addr_to_memory_data:** dict[int, *MemoryData*]

**normalized**

**edges_to_repair**

**property addr_type:** Literal['int', 'block_id', 'soot']

**property project**

**property node_addrs:** SortedList[int]

**nodes_by_addr**(*addr*)

**Return type**
Iterator[*CFGNode*]

**Parameters**
**addr** (*int*)

**has_node_addr**(*addr*)

**Return type**
bool

**Parameters**
**addr** (*int*)

**mark_node_addr_has_return**(*node_addr*, *has_return=True*)

**Return type**
None

**Parameters**

- **node_addr** (*int | SootAddressDescriptor*)
- **has_return** (*bool*)

**node_addr_has_return**(*node_addr*)

**Return type**
bool

**Parameters**
**node_addr** (*int | SootAddressDescriptor*)

**copy**()

**add_node**(*block_id*, *node*)

**Return type**
None

**Parameters**

- **block_id** (*int*)
- **node** (CFGNode)

**remove_node**(*block_id*, *node*)

Remove the given CFGNode instance. Note that this method *does not* remove the node from the graph.

**Parameters**

- **block_id** (int) – The Unique ID of the CFGNode.
- **node** (*CFGNode*) – The CFGNode instance to remove.

**Return type**
None

**Returns**
None

**has_node_id**(*node_id*)

**Return type**
bool

**get_node**(*block_id*)

Get a single node from Block ID.

**Parameters**
**block_id** (BlockID) – Block ID of the node.

**Return type**
*CFGNode* | None

**Returns**
The CFGNode, or None if the node does not exist.

**get_any_node**(*addr*, *is_syscall=None*, *anyaddr=False*, *force_fastpath=False*)

Get an arbitrary CFGNode (without considering their contexts) from our graph.

**Parameters**

- **addr** (int) – Address of the beginning of the basic block. Set anyaddr to True to support arbitrary address.
- **is_syscall** (bool | None) – Whether you want to get the syscall node or any other node. This is due to the fact that syscall SimProcedures have the same address as the target it returns to. None means get either, True means get a syscall node, False means get something that isn't a syscall node.
- **anyaddr** (bool) – If anyaddr is True, then addr doesn't have to be the beginning address of a basic block. By default the entire graph.nodes() will be iterated, and the first node containing the specific address is returned, which can be slow.
- **force_fastpath** (bool) – If force_fastpath is True, it will only perform a dict lookup in the graph._keys_by_addr dict.

**Return type**
*CFGNode* | None

**Returns**
A CFGNode if there is any that satisfies given conditions, or None otherwise

**get_all_nodes**(*addr*, *is_syscall=None*, *anyaddr=False*)

Get all CFGNodes whose address is the specified one.

**Parameters**

- **addr** (int) – Address of the node
- **is_syscall** (bool | None) – True returns the syscall node, False returns the normal CFGNode, None returns both
- **anyaddr** (*bool*)

**Return type**
list[*CFGNode*]

**Returns**
all CFGNodes

**get_all_nodes_intersecting_region**(*addr*, *size=1*)

Get all CFGNodes that intersect the given region.

**Parameters**

- **addr** (int) – Minimum address of target region.
- **size** (int) – Size of region, in bytes.

**Return type**
set[*CFGNode*]

**floor_addr**(*addr*)

Get the largest address that is less than or equal to the given address and has a CFGNode.

**Parameters**
**addr** (int) – The address to floor.

**Return type**
int | None

**Returns**
The largest address that is less than or equal to the given address and has a CFGNode, or None if no such address exists.

**ceil_addr**(*addr*)

Get the smallest address that is greater than or equal to the given address and has a CFGNode.

**Parameters**
**addr** (int) – The address to ceil.

**Return type**
int | None

**Returns**
The smallest address that is greater than or equal to the given address and has a CFGNode, or None if no such address exists.

**nodes**()

An iterator of all nodes in the graph.

**Returns**
The iterator.

**Return type**
iterator

**get_predecessors**(*cfgnode*, *excluding_fakeret=True*, *jumpkind=None*)

Get predecessors of a node in the control flow graph.

**Parameters**

- **cfgnode** (*CFGNode*) – The node.
- **excluding_fakeret** (bool) – True if you want to exclude all predecessors that is connected to the node with a fakeret edge.
- **jumpkind** (str | None) – Only return predecessors with the specified jumpkind. This argument will be ignored if set to None.

**Return type**
list[*CFGNode*]

**Returns**
A list of predecessors

**get_successors**(*node*, *excluding_fakeret=True*, *jumpkind=None*)

Get successors of a node in the control flow graph.

**Parameters**

- **node** (*CFGNode*) – The node.
- **excluding_fakeret** (bool) – True if you want to exclude all successors that is connected to the node with a fakeret edge.
- **jumpkind** (str | None) – Only return successors with the specified jumpkind. This argument will be ignored if set to None.

**Returns**
A list of successors

**Return type**
list[*CFGNode*]

**get_successors_and_jumpkinds**(*node*, *excluding_fakeret=True*)

Get a list of tuples where the first element is the successor of the CFG node and the second element is the jumpkind of the successor.

**Parameters**

- **node** (CFGNode) – The node.
- **excluding_fakeret** (*bool*) – True if you want to exclude all successors that are fall-through successors.

**Returns**
A list of successors and their corresponding jumpkinds.

**Return type**
list[tuple[*CFGNode*, str]]

**get_successors_and_jumpkind**(*node*, *excluding_fakeret=True*)

Get a list of tuples where the first element is the successor of the CFG node and the second element is the jumpkind of the successor.

**Parameters**

- **node** (CFGNode) – The node.
- **excluding_fakeret** (*bool*) – True if you want to exclude all successors that are fall-through successors.

**Returns**

A list of successors and their corresponding jumpkinds.

**Return type**

list[tuple[*CFGNode*, str]]

**get_predecessors_and_jumpkinds**(*node*, *excluding_fakeret=True*)

Get a list of tuples where the first element is the predecessor of the CFG node and the second element is the jumpkind of the predecessor.

**Parameters**

- **node** (*CFGNode*) – The node.
- **excluding_fakeret** (bool) – True if you want to exclude all predecessors that are fall-through predecessors.

**Return type**

list[tuple[*CFGNode*, str]]

**Returns**

A list of predecessors and their corresponding jumpkinds.

**get_predecessors_and_jumpkind**(*node*, *excluding_fakeret=True*)

Get a list of tuples where the first element is the predecessor of the CFG node and the second element is the jumpkind of the predecessor.

**Parameters**

- **node** (*CFGNode*) – The node.
- **excluding_fakeret** (bool) – True if you want to exclude all predecessors that are fall-through predecessors.

**Return type**

list[tuple[*CFGNode*, str]]

**Returns**

A list of predecessors and their corresponding jumpkinds.

**get_all_predecessors**(*cfgnode*, *depth_limit=None*)

Get all predecessors of a specific node on the control flow graph.

**Parameters**

- **cfgnode** (CFGNode) – The CFGNode object
- **depth_limit** (*int*) – Optional depth limit for the depth-first search

**Returns**

A list of predecessors in the CFG

**Return type**

list

**get_all_successors**(*cfgnode*, *depth_limit=None*)

Get all successors of a specific node on the control flow graph.

**Parameters**

- **cfgnode** (CFGNode) – The CFGNode object
- **depth_limit** (*int*) – Optional depth limit for the depth-first search

**Returns**
A list of successors in the CFG

**Return type**
list

**get_branching_nodes**()

Returns all nodes that has an out degree >= 2

**get_exit_stmt_idx**(*src_block*, *dst_block*)

Get the corresponding exit statement ID for control flow to reach destination block from source block. The exit statement ID was put on the edge when creating the CFG. Note that there must be a direct edge between the two blocks, otherwise an exception will be raised.

**Returns**
The exit statement ID

**add_memory_data**(*data_addr*, *data_type*, *data_size=None*)

Add a MemoryData entry to self.memory_data.

**Parameters**

- **data_addr** (int) – Address of the data
- **data_type** (*MemoryDataSort* | None) – Type of the memory data
- **data_size** (int | None) – Size of the memory data, or None if unknown for now.

**Return type**
bool

**Returns**
True if a new memory data entry is added, False otherwise.

**tidy_data_references**(*memory_data_addrs=None*, *exec_mem_regions=None*, *xrefs=None*, *seg_list=None*, *data_type_guessing_handlers=None*, *fill_gaps=True*, *new_mem_data_addrs=None*)

Go through all data references (or the ones as specified by memory_data_addrs) and determine their sizes and types if possible.

**Parameters**

- **memory_data_addrs** (list[int] | None) – A list of addresses of memory data, or None if tidying all known memory data entries.
- **exec_mem_regions** (list[tuple[int, int]] | None) – A list of start and end addresses of executable memory regions.
- **seg_list** (SegmentList | None) – The segment list that CFGFast uses during CFG recovery.
- **data_type_guessing_handlers** (list[Callable] | None) – A list of Python functions that will guess data types. They will be called in sequence to determine data types for memory data whose type is unknown.

- **fill_gaps** (bool) – If True, when a memory data entry is found to have a gap between its end and the next data entry, a new memory data entry will be created to fill the gap. fill_gaps should only be set to True at the end of CFG recovery when traversing the entire memory_data dict for the last time.
- **xrefs** (*XRefManager | None*)
- **new_mem_data_addrs** (*set[int] | None*)

**Return type**
bool

**Returns**
True if new data entries are found, False otherwise.

**remove_node_and_graph_node**(*node*)

Like *remove_node*, but also removes node from the graph.

**Parameters**
**node** (*CFGNode*) – The node to remove.

**Return type**
None

**get_intersecting_functions**(*addr*, *size=1*, *kb=None*)

Find all functions with nodes intersecting [addr, addr + size).

**Parameters**

- **addr** (int) – Minimum address of target region.
- **size** (int) – Size of region, in bytes.
- **kb** (*KnowledgeBase* | None) – Knowledge base to search for functions in.

**Return type**
set[*Function*]

**find_function_for_reflow_into_addr**(*addr*, *kb=None*)

Look for a function that flows into a new node at addr.

**Parameters**

- **addr** (int) – Address of new block.
- **kb** (*KnowledgeBase* | None) – Knowledge base to search for functions in.

**Return type**
*Function* | None

**clear_region_for_reflow**(*addr*, *size=1*, *kb=None*)

Remove nodes in the graph intersecting region [addr, addr + size).

Any functions that intersect the range, and their associated nodes in the CFG, will also be removed from the knowledge base for analysis.

**Parameters**

- **addr** (int) – Minimum address of target region.
- **size** (int) – Size of the region, in bytes.
- **kb** (*KnowledgeBase* | None) – Knowledge base to search for functions in.

**Return type**
None

### angr.knowledge_plugins.cfg.cfg_node

**class** angr.knowledge_plugins.cfg.cfg_node.**CFGNodeCreationFailure**

Bases: object

This class contains additional information for whenever creating a CFGNode failed. It includes a full traceback and the exception messages.

**__init__**(*exc_info=None*, *to_copy=None*)

**short_reason**

**long_reason**

**traceback**

**class** angr.knowledge_plugins.cfg.cfg_node.**CFGNode**

Bases: *Serializable*

This class stands for each single node in CFG.

**__init__**(*addr*, *size*, *cfg*, *simprocedure_name=None*, *no_ret=False*, *function_address=None*, *block_id=None*, *irsb=None*, *soot_block=None*, *instruction_addrs=None*, *thumb=False*, *byte_string=None*, *is_syscall=None*, *name=None*)

Note: simprocedure_name is not used to recreate the SimProcedure object. It's only there for better __repr__.

**Parameters**
**block_id** (BlockID | *int* | *None*)

**simprocedure_name**

**instruction_addrs**

**irsb**

**soot_block**

**property dirty**

**Setter accepts**
bool

**property name**

property successors

property predecessors

successors_and_jumpkinds(*excluding_fakeret=True*)

predecessors_and_jumpkinds(*excluding_fakeret=True*)

get_data_references(*kb=None*)

Get the known data references for this CFGNode via the knowledge base.

**Parameters**
**kb** – Which knowledge base to use; uses the global KB by default if none is provided

**Returns**
Generator yielding xrefs to this CFGNode's block.

**Return type**
iter

property accessed_data_references

Property providing a view of all the known data references for this CFGNode via the global knowledge base

**Returns**
Generator yielding xrefs to this CFGNode's block.

**Return type**
iter

property is_simprocedure

property callstack_key

copy()

merge(*other*)

Merges this node with the other, returning a new node that spans the both.

to_codenode()

property block: *Block* | *SootBlock* | None

class angr.knowledge_plugins.cfg.cfg_node.**CFGENode**

Bases: *CFGNode*

The CFGNode that is used in CFGEmulated.

input_state

looping_times

depth

creation_failure_info

final_states

syscall

return_target

property callstack_key

property creation_failed

property syscall_name: str | None

Drop saved states.

copy()

### angr.knowledge_plugins.cfg.indirect_jump

class angr.knowledge_plugins.cfg.indirect_jump.IndirectJumpType

Bases: object

The type of an indirect jump or call.

Jumptable_AddressLoadedFromMemory = 0

Jumptable_AddressComputed = 1

Vtable = 3

Unknown = 255

class angr.knowledge_plugins.cfg.indirect_jump.JumptableInfo

Bases: object

Describes a jump table or a vtable.

__init__(*addr*, *size*, *entry_size*, *entries*, ***, *entries_guessed=False*)

**Parameters**

- **addr** (*int | None*)
- **size** (*int*)
- **entry_size** (*int*)
- **entries** (*list[int]*)
- **entries_guessed** (*bool*)

addr

size

entry_size

entries

entries_guessed

serialize_to_cmessage()

classmethod parse_from_cmessage(*cmsg*)

**Return type**

*JumptableInfo*

class angr.knowledge_plugins.cfg.indirect_jump.**IndirectJump**

Bases: *Serializable*

Describes an indirect jump or call site.

**__init__**(*addr*, *ins_addr*, *func_addr*, *jumpkind*, *stmt_idx*, *resolved_targets=None*, *jumptable=False*, *jumptable_addr=None*, *jumptable_size=None*, *jumptable_entry_size=None*, *jumptable_entries=None*, *jumptable_entries_guessed=False*, *type_=255*)

**Parameters**

- **addr** (*int*)
- **ins_addr** (*int*)
- **func_addr** (*int*)
- **jumpkind** (*str*)
- **stmt_idx** (*int*)
- **resolved_targets** (*list[int] | None*)

EHHandlerType = 'eh-handlertype'

class angr.knowledge_plugins.cfg.memory_data.**MemoryData**

Bases: *Serializable*

MemoryData describes the syntactic content of a single address of memory.

*reference_size* reflects the size of *content*. It can be different from *size*, which is the actual size of the memory data item in memory. The intended way to get the actual content in memory is *self.content[:self.size]*.

**__init__**(*address*, *size*, *sort*, *pointer_addr=None*, *max_size=None*, *reference_size=None*)

**Parameters**

- **address** (*int*)
- **size** (*int*)
- **sort** (*str | None*)
- **pointer_addr** (*int | None*)
- **max_size** (*int | None*)
- **reference_size** (*int | None*)

**addr:** int

**size:** int

**reference_size:** int

**sort:** str | None

**max_size:** int | None

**pointer_addr:** int | None

**content:** bytes | None

**property address**

**copy**()

Make a copy of the MemoryData.

**Returns**
A copy of the MemoryData instance.

**Return type**
*MemoryData*

**fill_content**(*loader*)

Load data to fill self.content.

**Parameters**
**loader** – The project loader.

**Returns**
None

## angr.knowledge_plugins.cfg.spilling_cfg

CFG graph storage: CFGNode instances live in SpillingCFGNodeDict (LRU caching + LMDB spilling, following the SpillingFunctionDict pattern); the graph structure and edge attributes live in the packed Rust store CfgGraph.

**class** angr.knowledge_plugins.cfg.spilling_cfg.**SpillingCFGNodeDict**

Bases: object

A dict-like container for CFGNode instances with LRU caching and LMDB spilling.

This class keeps only the most recently accessed N nodes in memory, spilling others to an LMDB database on disk.

**Variables**

- **cache_limit** – The maximum number of nodes to keep in memory.
- **rtdb** (*RuntimeDb* | None) – A reference to the RuntimeDb knowledge base plugin.
- **_lru_order** (OrderedDict[tuple[int, int] | tuple[*BlockID*, int, int] | SootAddressDescriptor, None]) – An OrderedDict tracking the eviction order of cached nodes.
- **_spilled_keys** (set[tuple[int, int] | tuple[*BlockID*, int, int] | SootAddressDescriptor]) – A set of block_ids that have been spilled to LMDB.
- **_db_batch_size** (int) – The number of nodes that are evicted in a single batch.
- **_eviction_enabled** (bool) – A flag indicating whether eviction is currently enabled.

**__init__**(*rtdb*, *cfg_model=None*, *cache_limit=1000*, *db_batch_size=200*)

**Parameters**

- **rtdb** (RuntimeDb | *None*)
- **cfg_model** (CFGModel | *None*)
- **cache_limit** (*int*)
- **db_batch_size** (*int*)

**get**(*block_key*, *default=None*)

**Return type**
*CFGNode* | None

**Parameters**

- **block_key** (*tuple[int, int] | tuple[*BlockID*, int, int] | SootAddressDescriptor*)
- **default** (CFGNode | *None*)

**keys**()

**Return type**
Iterator[tuple[int, int] | tuple[*BlockID*, int, int] | SootAddressDescriptor]

**values**()

**Return type**
Iterator[*CFGNode*]

**items**()

**Return type**
Iterator[tuple[tuple[int, int] | tuple[*BlockID*, int, int] | SootAddressDescriptor, *CFGNode*]]

clear()

Return type
None

copy()

Return type
*SpillingCFGNodeDict*

property cache_limit: int

property db_batch_size: int

property cached_count: int

property spilled_count: int

property total_count: int

is_cached(*block_key*)

Return type
bool

Parameters
**block_key** (*tuple[int, int] | tuple[BlockID, int, int] | SootAddressDescriptor*)

bulk_import_serialized(*items*)

Bulk-import already-serialized CFG nodes directly into the LMDB backing store and register them as spilled, without deserializing them. Each payload must be in the format that _save_to_lmdb() writes: a type byte (0x00 for CFGNode, 0x01 for CFGENode) followed by the serialized protobuf message.

Parameters
**items** (list[tuple[tuple[int, int] | tuple[*BlockID*, int, int] | SootAddressDescriptor, bytes]]) – A list of (block key, serialized node payload) tuples.

Return type
None

load_all_spilled()

Return type
None

evict_all_cached()

Return type
None

class angr.knowledge_plugins.cfg.spilling_cfg.**CFGSegmentStore**

Bases: object

Backend for paged CfgGraph segments on the RuntimeDb: one LMDB sub-database shared by every graph of the knowledge base, keys prefixed with a per-graph random id.

DB_NAME = 'cfgsegments'

`__init__`(*rtdb*)

**Parameters**
**rtdb** (RuntimeDb)

`get`(*window*)

**Return type**
bytes | None

**Parameters**
**window** (*int*)

`put`(*window*, *data*)

**Return type**
None

**Parameters**

- **window** (*int*)
- **data** (bytes)

`delete`(*window*)

**Return type**
None

**Parameters**
**window** (*int*)

`delete_all`()

**Return type**
None

angr.knowledge_plugins.cfg.spilling_cfg.**get_block_key**(*node*)

Get the unique identifier for a CFGNode. Typically this unique identifier contains the address of the block and the looping_times of the block (in case there are multiple blocks with the same address, which may happen after loop unrolling in a CFGEmulated instance).

**Overloads**

- **node** () → tuple[int, int] | SootAddressDescriptor
- **node** () →

**Parameters**
**node** (*CFGNode* | *CFGENode*) – The CFGNode or CFGENode instance to get the block key for.

**Returns**
The unique identifier.

**Return type**
tuple[int, int] | tuple[BlockID, int, int] | *SootAddressDescriptor*

angr.knowledge_plugins.cfg.spilling_cfg.**block_key_to_addr**(*block_key*)

Extract the address from a block key.

**Overloads**

- **block_key** (tuple[int, int] | tuple[*BlockID*, int, int]) → int
- **block_key** () →

**Parameters**
**block_key** (*tuple[int, int] | tuple[BlockID, int, int] | SootAddressDescriptor*)

**Return type**
int | *SootAddressDescriptor*

angr.knowledge_plugins.cfg.spilling_cfg.**block_key_to_size**(*block_key*)

Extract the size from a block key, if present.

**Return type**
int | None

**Parameters**
**block_key** (*tuple[int, int] | tuple[BlockID, int, int] | SootAddressDescriptor*)

**class** angr.knowledge_plugins.cfg.spilling_cfg.**SpillingCFG**

Bases: object

A graph wrapper that stores CFGNode instances in a spilling dict while keeping the graph structure in a packed Rust store (CfgGraph) keyed by block keys.

This provides a networkx-compatible interface while supporting disk-backed storage for the nodes of large CFGs.

addr_type must be "int", "block_id", or "soot". You can change addr_type before the first node is inserted but not after, since it affects how keys are mapped onto the store.

**__init__**(*rtdb=None*, *cfg_model=None*, *cache_limit=None*, *db_batch_size=800*, *addr_type='int'*, *segment_budget=None*)

**Parameters**

- **segment_budget** (int | None) – Byte budget for resident graph segments; the graph is paged to the RuntimeDb from the start. Setting this parameter to None means the whole graph will be kept resident in RAM.
- **rtdb** (*RuntimeDb | None*)
- **cfg_model** (*CFGModel | None*)
- **cache_limit** (*int | None*)
- **db_batch_size** (*int*)
- **addr_type** (*CFG_ADDR_TYPES*)

**property addr_type:** str

**property paged:** bool

Whether graph segments are paged to the RuntimeDb.

**property segment_budget:** int | None

**segment_stats**()

Segment paging counters: loads, evictions, writebacks, resident/total segments, resident bytes.

**Return type**
dict

**flush**()

Compact resident segments and write dirty ones back to the backend (no-op when not paged).

**Return type**
None

**get_node_by_key**(*block_key*)

Get a CFGNode by block key.

**Return type**
*CFGNode*

**Parameters**
**block_key** (*tuple[int, int] | tuple[BlockID, int, int] | SootAddressDescriptor*)

**property node_keys: Iterator[tuple[int, int] | tuple[*BlockID*, int, int] | SootAddressDescriptor]**

Get an iterator over all block_keys in the graph.

**add_node**(*node*, ***attr*)

**Return type**
None

**Parameters**
**node** (CFGNode)

**export_serialized_nodes**()

Export every node as the serialized bytes of its CFGNode/CFGENode protobuf message (without the LMDB type byte), e.g. for dumping into an angr database.

Nodes are byte-copied directly out of the LMDB backing store without being deserialized and re-serialized.

**Return type**
list[tuple[tuple[int, int] | tuple[*BlockID*, int, int] | SootAddressDescriptor, bytes, bool]]

**Returns**
A list of (block key, serialized CFGNode message bytes, copied_from_lmdb) tuples.

**bulk_import_serialized_nodes**(*items*)

Bulk-import already-serialized nodes directly into the LMDB backing store as spilled entries, without constructing any CFGNode objects.

**Parameters**
**items** (list[tuple[tuple[int, int] | tuple[*BlockID*, int, int] | SootAddressDescriptor, int | SootAddressDescriptor, bytes]]) – A list of (block key, node address, serialized node payload) tuples. See SpillingCFGNodeDict.bulk_import_serialized() for the payload format.

**Return type**
None

**remove_node**(*node*)

**Return type**
None

**Parameters**
**node** (CFGNode)

**has_node**(*node*)

**Return type**
bool

**Parameters**
**node** (CFGNode)

**nodes_by_addr**(*addr*)

**Return type**
Iterator[*CFGNode*]

**Parameters**
**addr** (*int*)

**first_key_at_addr**(*addr*)

The block key of the first node at the given address, or None.

**Return type**
tuple[int, int] | tuple[*BlockID*, int, int] | SootAddressDescriptor | None

**Parameters**
**addr** (*int | SootAddressDescriptor*)

**has_node_addr**(*addr*)

**Return type**
bool

**Parameters**
**addr** (*int*)

**node_addrs**()

Distinct addresses of all nodes.

**Return type**
list[int | SootAddressDescriptor]

**number_of_nodes**()

**Return type**
int

**property nodes: _NodeView**

Return a view of nodes supporting len(), iteration, and call with data=True.

**add_edge**(*src*, *dst*, ***attr*)

**Return type**
None

**Parameters**

- **src** (CFGNode)
- **dst** (CFGNode)

**add_edge_by_key**(*src_block_key*, *dst_block_key*, ***attr*)

**Return type**
None

**Parameters**

- **src_block_key** (*tuple[int, int] | tuple[BlockID, int, int] | SootAddressDescriptor*)
- **dst_block_key** (*tuple[int, int] | tuple[BlockID, int, int] | SootAddressDescriptor*)

**remove_edge**(*src*, *dst*)

**Return type**
None

**Parameters**

- **src** (CFGNode)
- **dst** (CFGNode)

**remove_edge_by_key**(*src_block_key*, *dst_block_key*)

**Return type**
None

**Parameters**

- **src_block_key** (*tuple[int, int] | tuple[BlockID, int, int] | SootAddressDescriptor*)
- **dst_block_key** (*tuple[int, int] | tuple[BlockID, int, int] | SootAddressDescriptor*)

**has_edge**(*src*, *dst*)

**Return type**
bool

**Parameters**

- **src** (CFGNode)
- **dst** (CFGNode)

**has_edge_by_key**(*src_block_key*, *dst_block_key*)

**Return type**
bool

**Parameters**

- **src_block_key** (*tuple[int, int] | tuple[BlockID, int, int] | SootAddressDescriptor*)
- **dst_block_key** (*tuple[int, int] | tuple[BlockID, int, int] | SootAddressDescriptor*)

**get_edge_data**(*src*, *dst*, *default=None*)

**Return type**
dict | None

**Parameters**

- **src** (CFGNode)
- **dst** (CFGNode)

number_of_edges()

**Return type**
int

property edges: _EdgeView

Return a view of edges supporting len(), iteration, and call with data=True.

property call_destination_keys: set[tuple[int, int] | tuple[*BlockID*, int, int] | SootAddressDescriptor]

Return the set of block keys that are destinations of call/syscall edges.

call_destination_nodes()

Yield CFGNode for each call/syscall destination.

**Return type**
Iterator[*CFGNode*]

predecessors(*node*)

**Return type**
Iterator[*CFGNode*]

**Parameters**
**node** (CFGNode)

successors(*node*)

**Return type**
Iterator[*CFGNode*]

**Parameters**
**node** (CFGNode)

property in_edges: _InEdgeView

Return a view of in-edges supporting call, subscript, len, and iteration.

property out_edges: _OutEdgeView

Return a view of out-edges supporting call, subscript, len, and iteration.

property in_degree: _InDegreeView

Return a view of in-degrees supporting call, subscript, len, and iteration.

property out_degree: _OutDegreeView

Return a view of out-degrees supporting call, subscript, len, and iteration.

out_edges_by_key(*key*, *data=False*)

**Overloads**

- **key** (), **data** (Literal[False]) = False → Generator[tuple[tuple[int, int] | tuple[*BlockID*, int, int] | SootAddressDescriptor, tuple[int, int] | tuple[*BlockID*, int, int] | SootAddressDescriptor]]
- **key** (), *, **data** (Literal[True]) → Generator[tuple[tuple[int, int] | tuple[*BlockID*, int, int] | SootAddressDescriptor, tuple[int, int] | tuple[*BlockID*, int, int] | SootAddressDescriptor, dict]]

**Parameters**

- **key** (*tuple[int, int] | tuple[*BlockID, *int, int] | SootAddressDescriptor*)

- **data** (*bool*)

**Return type**
*Generator*[tuple[tuple[int, int] | tuple[BlockID, int, int] | *SootAddressDescriptor*, tuple[int, int] | tuple[BlockID, int, int] | *SootAddressDescriptor*] | tuple[tuple[int, int] | tuple[BlockID, int, int] | *SootAddressDescriptor*, tuple[int, int] | tuple[BlockID, int, int] | *SootAddressDescriptor*, dict]]

**out_degree_by_key**(*key*)

**Return type**
int

**Parameters**
**key** (*tuple[int, int] | tuple[BlockID, int, int] | SootAddressDescriptor*)

**copy**()

**Return type**
*SpillingCFG*

**subgraph**(*nodes*)

Return a subgraph as a regular networkx DiGraph with CFGNode instances. This is useful for algorithms that need a pure networkx graph.

**Return type**
DiGraph

**to_networkx**()

Convert to a pure networkx DiGraph with CFGNode instances as nodes. Warning: This loads all spilled nodes into memory.

**Return type**
DiGraph

**from_networkx**(*nx_graph*)

Load graph structure from a networkx DiGraph with CFGNode instances as nodes.

**Return type**
None

**Parameters**
**nx_graph** (*DiGraph*)

**property cache_limit: int | None**

**property db_batch_size: int**

**property cached_count: int**

**property spilled_count: int**

**load_all_spilled**()

**Return type**
None

**evict_all_cached**()

**Return type**
None

**set_rtdb**(*rtdb*)

(Re-)attach a RuntimeDb to this graph and its node store. This is used after unpickling (rtdb references are not preserved across pickling) so that node spilling works again.

**Return type**
None

**Parameters**
**rtdb** (RuntimeDb | *None*)

### angr.knowledge_plugins.cfg.types

angr.knowledge_plugins.cfg.types.**SOOTNODE_K**

alias of SootAddressDescriptor

## 10.24.4 angr.knowledge_plugins.comments

**class** angr.knowledge_plugins.comments.**CommentKind**

Bases: IntEnum

How a comment is displayed.

PLAIN shows only at its own address. FUNCTION renders as a header block above the function, which is also what the decompiler does with a comment on a function entry. REPEATABLE additionally shows at every location referencing the commented address.

**PLAIN = 0**

**FUNCTION = 1**

**REPEATABLE = 2**

**property display_name: str**

**__new__**(*value*)

**class** angr.knowledge_plugins.comments.**Comment**

Bases: object

A comment together with its display metadata. Rebuilt on demand from the knowledge base.

**__init__**(*addr*, *text*, *kind*, *func_addr=None*, *func_name=None*)

**Parameters**

- **addr** (*int*)
- **text** (*str*)
- **kind** (CommentKind)
- **func_addr** (*int* | *None*)
- **func_name** (*str* | *None*)

**Return type**
None

**addr**

**text**

**kind**

**func_addr**

**func_name**

**property first_line: str**

**class** angr.knowledge_plugins.comments.**Comments**

Bases: *KnowledgeBasePlugin*, dict

Tracks comments via a Dict of Address -> Text, along with a per-address *CommentKind*.

**property kinds: dict[int, *CommentKind*]**

Explicitly-set comment kinds. Addresses not present here use *kind_of()* defaults.

**kind_of**(*addr*)

**Return type**
*CommentKind*

**Parameters**
**addr** (*int*)

**set_kind**(*addr*, *kind*)

Set the display kind for the comment at addr, or reset it to the default with None.

**Return type**
None

**Parameters**

- **addr** (*int*)
- **kind** (CommentKind | *None*)

**is_function_entry**(*addr*)

**Return type**
bool

**Parameters**
**addr** (*int*)

**function_comment**(*func_addr*)

The comment rendered as a function's header block, if any.

**Return type**
str | None

**Parameters**
**func_addr** (*int*)

**inline_comment**(*addr*)

The comment rendered next to the instruction at addr. A comment that already renders as a function header block is not repeated inline.

**Return type**
str | None

**Parameters**
**addr** (*int*)

**iter_comments**()

All comments in address order, with their kinds and owning functions.

**Return type**
Iterator[*Comment*]

**repeatable_comments_at**(*ins_addr*)

Repeatable comments that should show at `ins_addr` because it references their address.

**Return type**
list[tuple[int, str]]

**Parameters**
**ins_addr** (*int*)

**invalidate**()

Drop the cached repeatable-comment map, e.g. after xrefs or functions change.

**Return type**
None

### 10.24.5 angr.knowledge_plugins.custom_strings

**class** angr.knowledge_plugins.custom_strings.**CustomStrings**

Bases: *KnowledgeBasePlugin*

Store new strings that are recovered during various analysis. Each string has a unique ID associated.

**__init__**(*kb*)

**allocate**(*s*)

**Return type**
int

**Parameters**
**s** (bytes)

**copy**()

### 10.24.6 angr.knowledge_plugins.data

**class** angr.knowledge_plugins.data.**Data**

Bases: *KnowledgeBasePlugin*

The knowledge what purpose this plugin serves has been lost to the passing of time but the linter does not care for these failures of mere mortals and demands a docstring anyway. The pact has been made, and no violations of the rules will be tolerated, even if the spirit does not match the letter. Making the plugin smaller has only increased the weight of the failure, and thus this file has drawn its ire.

The only thing left to do is to attempt to find meaning in the meaninglessness, as the only act of rebellion against the uncaring forces that bind us. For is this not what being human is all about?

**copy**()

### 10.24.7 angr.knowledge_plugins.debug_variables

**class** angr.knowledge_plugins.debug_variables.**DebugVariableContainer**

Bases: object

Variable tree for variables with same name to lock up which variable is visible at a given program counter address.

**__init__**()

It is recommended to use DebugVariableManager.add_variable() instead

**from_pc**(*pc*)

Returns the visible variable (if any) for a given pc address.

**Return type**
Variable

**class** angr.knowledge_plugins.debug_variables.**DebugVariable**

Bases: *DebugVariableContainer*

**Variables**

- **low_pc** – Start of the visibility scope of the variable as program counter address (rebased)
- **high_pc** – End of the visibility scope of the variable as program counter address (rebased)
- **cle_variable** – Original variable from cle

**__init__**(*low_pc*, *high_pc*, *cle_variable*)

It is recommended to use DebugVariableManager.add_variable() instead

**Parameters**

- **low_pc** (*int*)
- **high_pc** (*int*)
- **cle_variable** (*Variable*)

**contains**(*dvar*)

**Return type**
bool

**Parameters**
**dvar** (DebugVariable)

**test_unsupported_overlap**(*dvar*)

Test for an unsupported overlapping

**Parameters**
**dvar** (*DebugVariable*) – Second DebugVariable to compare with

**Return type**
bool

**Returns**
True if there is an unsupported overlapping

**class** angr.knowledge_plugins.debug_variables.**DebugVariableManager**

Bases: *KnowledgeBasePlugin*

Structure to manage and access variables with different visibility scopes.

__init__(*kb*)

**Parameters**
**kb** (KnowledgeBase)

from_name_and_pc(*var_name*, *pc_addr*)

Get a variable from its string in the scope of pc.

**Return type**
Variable

**Parameters**

- **var_name** (*str*)
- **pc_addr** (*int*)

from_name(*var_name*)

Get the variable container for all variables named var_name

**Parameters**
**var_name** (str) – name for a variable

**Return type**
*DebugVariableContainer*

add_variable(*cle_var*, *low_pc*, *high_pc*)

Add/load a variable

**Parameters**

- **cle_variable** – The variable to add
- **low_pc** (int) – Start of the visibility scope of the variable as program counter address (rebased)
- **high_pc** (int) – End of the visibility scope of the variable as program counter address (rebased)
- **cle_var** (*Variable*)

add_variable_list(*vlist*, *low_pc*, *high_pc*)

Add all variables in a list with the same visibility range

**Parameters**

- **vlist** (list[Variable]) – A list of cle variables to add
- **low_pc** (int) – Start of the visibility scope as program counter address (rebased)
- **high_pc** (int) – End of the visibility scope as program counter address (rebased)

load_from_dwarf(*elf_object=None*, *cu=None*)

Automatically load all variables (global/local) from the DWARF debugging info

**Parameters**

- **elf_object** (ELF) – Optional, when only one elf object should be considered (e.g. p.loader.main_object)
- **cu** (CompilationUnit) – Optional, when only one compilation unit should be considered

### 10.24.8 angr.knowledge_plugins.functions

**class** angr.knowledge_plugins.functions.**Function**

Bases: *Serializable*

A representation of a function and various information about it.

**Variables**

- **meta_only** – Whether this function only contains meta-information and in read-only mode.
- **_dirty** – Whether this function has been modified since last serialization.
- **evicted** – Whether this function has been evicted from FunctionManager to external storage.

**__init__**(*function_manager*, *addr*, *name=None*, *syscall=None*, *is_simprocedure=None*, *binary_name=None*, *is_plt=None*, *returning=None*, *alignment=False*, *calling_convention=None*, *prototype=None*, *prototype_libname=None*, *prototype_source=None*, *is_prototype_guessed=True*)

Function constructor. If the optional parameters are not provided, they will be automatically determined upon the creation of a Function object.

**Parameters**

- **addr** (int) – The address of the function.
- **name** (*str*) – The name of the function.
- **syscall** (*bool*) – Whether this function is a syscall or not.
- **is_simprocedure** (bool | None) – Whether this function is a SimProcedure or not.
- **binary_name** (*str*) – Name of the binary where this function is.
- **is_plt** (bool | None) – If this function is a PLT entry.
- **returning** (*bool*) – If this function returns.
- **alignment** (*bool*) – If this function acts as an alignment filler. Such functions usually only contain nops.
- **function_manager** (FunctionManager | *None*)
- **calling_convention** (SimCC | *None*)
- **prototype** (SimTypeFunction | *None*)
- **prototype_libname** (*str* | *None*)
- **prototype_source** (PrototypeSource | *None*)
- **is_prototype_guessed** (*bool*)

**is_default_name**

**binary_name**

**property name**

**property from_signature: str | None**

**property project: *Project* | None**

**property returning**

**property calling_convention:** *SimCC* | None

**property prototypes:** dict[str, *SimTypeFunction* | None]

A snapshot of every flavor's prototype, keyed by decompilation flavor. Write through set_prototype(); the default-flavor entry is also exposed as .prototype.

**property prototype_sources:** dict[str, *PrototypeSource*]

A snapshot of every flavor's prototype source; the default-flavor entry is also exposed as .prototype_source.

**property prototype:** *SimTypeFunction* | None

**get_prototype**(*flavor*)

The prototype a decompilation of the given flavor should use: the flavor's own entry, or the C prototype when the flavor has none. The C flavor never falls back to another flavor.

**Return type**
*SimTypeFunction* | None

**Parameters**
**flavor** (*str* | *None*)

**has_prototype_for_flavor**(*flavor*)

Whether the flavor has its own entry (as opposed to falling back to the C prototype).

**Return type**
bool

**Parameters**
**flavor** (*str* | *None*)

**uses_default_prototype_for**(*flavor*)

Whether get_prototype(flavor) is the default flavor's (C) prototype, e.g., to dereference it by library.

**Return type**
bool

**Parameters**
**flavor** (*str* | *None*)

**get_prototype_source**(*flavor*)

The source of the prototype get_prototype(flavor) returns.

**Return type**
*PrototypeSource*

**Parameters**
**flavor** (*str* | *None*)

**set_prototype**(*flavor*, *proto*, *source=None*)

Set the prototype of a flavor. A flavor's first entry starts with the source of the prototype it used to fall back to (the C one) unless `source` is given.

**Return type**
None

**Parameters**

- **flavor** (*str* | *None*)
- **proto** (SimTypeFunction | *None*)
- **source** (PrototypeSource | *None*)

**set_prototype_source**(*flavor*, *source*)

Set the source of a flavor's prototype; a flavor without an entry gets one that falls back to C's.

**Return type**
None

**Parameters**

- **flavor** (*str | None*)
- **source** (PrototypeSource)

**clear_prototype**(*flavor*)

Drop a flavor's own entry so that it falls back to the C prototype; clearing C sets it to None.

**Return type**
None

**Parameters**
**flavor** (*str | None*)

**property prototype_libname**

**Setter accepts**
str | None

**property is_prototype_guessed: bool**

**is_prototype_guessed_for**(*flavor*)

**Return type**
bool

**Parameters**
**flavor** (*str | None*)

**property is_prototype_groundtruth: bool**

True if the prototype comes from outside of the decompiler (SimProcedures, signatures, or the user) and may be fed back into type inference as ground truth. Prototypes inferred by the decompiler itself are excluded so that re-decompiling a function does not freeze its own earlier guess.

**is_prototype_groundtruth_for**(*flavor*)

is_prototype_groundtruth for the prototype get_prototype(flavor) returns.

**Return type**
bool

**Parameters**
**flavor** (*str | None*)

**property prototype_source: *PrototypeSource***

**property info: *FunctionInfo***

**Setter accepts**
*FunctionInfo* | dict

**property is_plt: bool**

**property is_simprocedure: bool**

**property is_syscall: bool**

property is_alignment: bool

transition_out_edges(*node*)

(successor, edge data) pairs of a node, in the order of `transition_graph.out_edges(node, data=True)`, without building the networkx transition graph when it does not exist yet.

**Return type**
list[tuple[*CodeNode*, Mapping[str, Any]]]

**Parameters**
**node** (CodeNode)

transition_in_edges(*node*)

(predecessor, edge data) pairs of a node, in the order of `transition_graph.in_edges(node, data=True)`, without building the networkx transition graph when it does not exist yet.

**Return type**
list[tuple[*CodeNode*, Mapping[str, Any]]]

**Parameters**
**node** (CodeNode)

has_node(*node*)

**Return type**
bool

**Parameters**
**node** (CodeNode)

set_edge_outside(*src*, *dst*, *outside*)

**Return type**
None

**Parameters**

- **src** (CodeNode)
- **dst** (CodeNode)
- **outside** (*bool*)

add_graph_node(*node*)

Add a node to the transition graph without registering it as a local block.

**Return type**
None

**Parameters**
**node** (CodeNode)

add_graph_edge(*src*, *dst*, *type=None*, *outside=None*, *ins_addr=<object object>*, *stmt_idx=<object object>*, *confirmed=None*)

Add or update an edge of the transition graph.

**Return type**
None

**Parameters**

- **src** (CodeNode)
- **dst** (CodeNode)

- **type** (*str | None*)
- **outside** (*bool | None*)
- **ins_addr** (*int | None*)
- **stmt_idx** (*int | None*)
- **confirmed** (*bool | None*)

**remove_graph_node**(*node*)

Remove a node and its edges from the transition graph.

**Return type**
None

**Parameters**
**node** (CodeNode)

**set_edge_confirmed**(*src*, *dst*, *confirmed*)

**Return type**
None

**Parameters**

- **src** (CodeNode)
- **dst** (CodeNode)
- **confirmed** (*bool*)

**property transition_graph:** *TransitionGraph*

A read-only networkx view of the transition graph, created on-demand and kept in sync with the Function's updates.

**property startpoint:** *CodeNode* | None

**property blocks**

An iterator of all local blocks in the current function.

**Returns**
angr.lifter.Block instances.

**property code_nodes:** dict[int, *CodeNode*]

**property cyclomatic_complexity**

The cyclomatic complexity of the function.

Cyclomatic complexity is a software metric used to indicate the complexity of a program. It is a quantitative measure of the number of linearly independent paths through a program's source code. It is computed using the formula: M = E - N + 2P, where E = the number of edges in the graph, N = the number of nodes in the graph, P = the number of connected components.

The cyclomatic complexity value is lazily computed and cached for future use. Initially this value is None until it is computed for the first time

**Returns**
The cyclomatic complexity of the function.

**Return type**
int

property xrefs: Iterator[XRef]

An iterator of all xrefs of the current function.

**Returns**
angr.knowledge_plugins.xrefs.xref.XRef instances.

property block_addrs

An iterator of all local block addresses in the current function.

**Returns**
block addresses.

property block_addrs_set

Return a set of block addresses for a better performance of inclusion tests.

**Returns**
A set of block addresses.

**Return type**
set

get_block(*addr*, *size=None*, *byte_string=None*)

Getting a block out of the current function.

**Parameters**

- **addr** (int) – The address of the block.
- **size** (int | None) – The size of the block. This is optional. If not provided, angr will load
- **byte_string** (bytes | None)

**Returns**

get_block_size(*addr*)

**Return type**
int | None

**Parameters**
**addr** (*int*)

property nodes: Iterable[CodeNode]

get_node(*addr*)

**Return type**
*BlockNode* | None

property has_unresolved_jumps

property has_unresolved_calls

property operations

All of the operations that are done by this functions.

property code_constants

All of the constants that are used by this functions's code.

classmethod parse_from_cmessage(*cmsg*, ***kwargs*)

**Parameters**
**cmsg**

**Return Function**
The function instantiated out of the cmsg data.

`string_references`(*minimum_length=2*)

All of the constant string references used by this function.

**Parameters**
**minimum_length** – The minimum length of strings to find (default is 1)

**Returns**
A generator yielding tuples of (address, string) where is address is the location of the string in memory.

`property local_runtime_values`

Tries to find all runtime values of this function which do not come from inputs. These values are generated by starting from a blank state and reanalyzing the basic blocks once each. Function calls are skipped, and back edges are never taken so these values are often unreliable, This function is good at finding simple constant addresses which the function will use or calculate.

**Returns**
a set of constants

`property num_arguments`

`property endpoints: list[CodeNode]`

`property endpoints_with_type: defaultdict[str, set[CodeNode]]`

`property ret_sites: list[CodeNode]`

`property jumpout_sites: list[CodeNode]`

`property retout_sites: list[CodeNode]`

`property callout_sites: list[CodeNode]`

`property size`

`property binary`

Get the object this function belongs to. :return: The object this function belongs to.

`property offset: int`

the function's binary offset (i.e., non-rebased address)

**Type**
return

`property symbol: Symbol | None`

the function's Symbol, if any

**Type**
return

`property pseudocode: str | None`

the function's pseudocode

**Type**
return

`property dirty: bool`

mark_dirty()

**Return type**
None

add_jumpout_site(*node*)

Add a custom jumpout site.

**Parameters**
**node** (*CodeNode*) – The address of the basic block that control flow leaves during this transition.

**Returns**
None

add_retout_site(*node*)

Add a custom retout site.

Retout (returning to outside of the function) sites are very rare. It mostly occurs during CFG recovery when we incorrectly identify the beginning of a function in the first iteration, and then correctly identify that function later in the same iteration (function alignments can lead to this bizarre case). We will mark all edges going out of the header of that function as a outside edge, because all successors now belong to the incorrectly-identified function. This identification error will be fixed in the second iteration of CFG recovery. However, we still want to keep track of jumpouts/retouts during the first iteration so other logic in CFG recovery still work.

**Parameters**
**node** (*CodeNode*) – The address of the basic block that control flow leaves the current function after a call.

**Returns**
None

clear_transition_graph()

confirm_fakeret(*src*, *dst*)

transit_to(*from_node*, *to_node*, *outside=False*, *ins_addr=None*, *stmt_idx=None*, *is_exception=False*, *update_func_block_count=True*)

Registers an edge between basic blocks in this function's transition graph. Arguments are CodeNode objects.

**Parameters**

- **from_node** (*CodeNode*) – The address of the basic block that control flow leaves during this transition.
- **to_node** – The address of the basic block that control flow enters during this transition.
- **outside** (*bool*) – If this is a transition to another function, e.g. tail call optimization
- **update_func_block_count** (*bool*)

**Returns**
None

call_to(*from_node*, *to_func*, *ret_node*, *stmt_idx=None*, *ins_addr=None*, *return_to_outside=False*, *syscall=False*, *update_func_block_count=True*)

Registers an edge between the caller basic block and callee function.

**Parameters**

- **from_node** (*angr.knowledge.CodeNode*) – The basic block that control flow leaves during the transition.
- **to_func** (*FuncNode* | *HookNode*) – The function that we are calling, represented as a FuncNode.
- **ret_node** (*angr.knowledge.CodeNode or None*) – The basic block that control flow should return to after the function call.
- **stmt_idx** (*int, str or None*) – Statement ID of this call.
- **ins_addr** (*int or None*) – Instruction address of this call.
- **syscall** (*bool*)
- **update_func_block_count** (*bool*)

**fakeret_to**(*from_node*, *to_node*, *confirmed=None*, *to_outside=False*, *update_func_block_count=True*)

**Parameters**
**update_func_block_count** (*bool*)

**remove_fakeret**(*from_node*, *to_node*)

**remove_edge**(*from_node*, *to_node*)

**Return type**
None

**Parameters**

- **from_node** (CodeNode)
- **to_node** (CodeNode)

**return_from_call**(*from_func*, *to_node*, *to_outside=False*, *confirm_fakeret=True*)

**Parameters**

- **from_func** (FuncNode | HookNode)
- **confirm_fakeret** (*bool*)

**update_func_block_count**()

Update the cached block count of this function in the function manager.

**Return type**
None

**register**(*is_local*, *node*, *update_func_block_count=True*)

Register a node with the function and return its ID. The first object that is registered for a fresh ID becomes the ID's canonical CodeNode object.

**Return type**
int

**Parameters**

- **is_local** (*bool*)
- **node** (CodeNode)
- **update_func_block_count** (*bool*)

**register_node**(*is_local*, *node*, *update_func_block_count=True*)

**Return type**
*CodeNode*

**Parameters**

- **is_local** (*bool*)
- **node** (CodeNode)
- **update_func_block_count** (*bool*)

**add_return_site**(*return_site*)

Registers a basic block as a site for control flow to return from this function.

**Parameters**
**return_site** (*CodeNode*) – The block node that ends with a return.

**add_call_site**(*call_site_addr*, *call_target_addr*, *retn_addr*)

Registers a basic block as calling a function and returning somewhere.

**Parameters**

- **call_site_addr** – The address of a basic block that ends in a call.
- **call_target_addr** – The address of the target of said call.
- **retn_addr** – The address that said call will return to.

**add_endpoint**(*endpoint_node*, *sort*)

Registers an endpoint with a type of *sort*. The type can be one of the following: - call: calling a function that does not return - return: returning from the current function - transition: a jump/branch targeting a different function

It is possible for a block to act as two different sorts of endpoints. For example, consider the following block:

.text:0000000000024350 mov eax, 1 .text:0000000000024355 lock xadd [rdi+4], eax .text:000000000002435A retn

**VEX code:**
00 | —— IMark(0x424350, 5, 0) —— 01 | PUT(rax) = 0x0000000000000001 02 | PUT(rip) = 0x0000000000424355 03 | —— IMark(0x424355, 5, 0) —— 04 | t11 = GET:I64(rdi) 05 | t10 = Add64(t11,0x0000000000000004) 06 | t0 = LDle:I32(t10) 07 | t2 = Add32(t0,0x00000001) 08 | t(4,4294967295) = CASle(t10 :: (t0,None)->(t2,None)) 09 | t14 = CasCmpNE32(t4,t0) 10 | if (t14) { PUT(rip) = 0x424355; Ijk_Boring } 11 | PUT(cc_op) = 0x0000000000000003 12 | t15 = 32Uto64(t0) 13 | PUT(cc_dep1) = t15 14 | PUT(cc_dep2) = 0x0000000000000001 15 | t17 = 32Uto64(t0) 16 | PUT(rax) = t17 17 | PUT(rip) = 0x000000000042435a 18 | —— IMark(0x42435a, 1, 0) —— 19 | t6 = GET:I64(rsp) 20 | t7 = LDle:I64(t6) 21 | t8 = Add64(t6,0x0000000000000008) 22 | PUT(rsp) = t8 23 | t18 = Sub64(t8,0x0000000000000080) 24 | ====== AbiHint(0xt18, 128, t7) ====== NEXT: PUT(rip) = t7; Ijk_Ret

This block acts as both a return endpoint and a transition endpoint (transitioning to 0x424355).

**Parameters**

- **endpoint_node** – The endpoint node.
- **sort** – Type of the endpoint.

**Returns**
None

**mark_nonreturning_calls_endpoints**()

Iterate through all call edges in transition graph. For each call a non-returning function, mark the source basic block as an endpoint.

This method should only be executed once all functions are recovered and analyzed by CFG recovery, so we know whether each function returns or not.

**Returns**
None

**property call_sites: dict[int, tuple[int | None, int | None]]**

**call_edge_addrs**()

(call-site block address, callee address) of every call edge, in transition-graph order. Unlike call_sites, a block with several call targets contributes one pair per target.

**Return type**
list[tuple[int, int]]

**jumpout_targets**()

(jump-out site block address, target address, branch instruction address) of every transition that leaves this function, such as a tail jump. The instruction address is None when the CFG did not record it.

**Return type**
list[tuple[int, int, int | None]]

**unconfirmed_fakeret_edges**()

Fake-return edges that have not been confirmed by a return of the callee, in transition-graph order.

**Return type**
list[tuple[*CodeNode*, *CodeNode*]]

**outgoing_function_targets**()

Addresses of the functions this function calls or jumps out to.

**Return type**
list[int]

**get_call_sites**()

Gets a list of all the basic blocks that end in calls.

**Return type**
Iterable[int]

**Returns**
A view of the addresses of the blocks that end in calls.

**get_call_target**(*callsite_addr*)

Get the target of a call.

**Parameters**
**callsite_addr** – The address of a basic block that ends in a call.

**Returns**
The target of said call, or None if callsite_addr is not a callsite.

**get_call_return**(*callsite_addr*)

Get the hypothetical return address of a call.

**Parameters**
**callsite_addr** – The address of the basic block that ends in a call.

**Returns**
The likely return target of said call, or None if callsite_addr is not a callsite.

**property graph:** *TransitionGraph*

Get a local transition graph. A local transition graph is a transition graph that only contains nodes that belong to the current function. All edges, except for the edges going out from the current function or coming from outside the current function, are included.

The generated graph is a read-only view cached in self._local_transition_graph.

**Returns**
A local transition graph.

**graph_ex**(*exception_edges=True*)

Get a local transition graph with a custom configuration. A local transition graph is a transition graph that only contains nodes that belong to the current function. This method allows user to include certain types of edges and nodes, such as exception edges.

The generated graph is not cached. It is a mutable copy.

**Parameters**
**exception_edges** (*bool*) – Should exception edges and the nodes that are only reachable through exception edges be kept.

**Return type**
networkx.DiGraph[CodeNode]

**Returns**
A local transition graph with a special configuration.

**transition_graph_ex**(*exception_edges=True*)

Get a transition graph with a custom configuration. This method allows user to exclude certain types of edges together with the nodes that are only reachable through such edges, such as exception edges.

The generated graph is not cached.

**Parameters**
**exception_edges** (*bool*) – Should exception edges and the nodes that are only reachable through exception edges be kept.

**Returns**
A local transition graph with a special configuration.

**Return type**
networkx.DiGraph

**subgraph**(*ins_addrs*)

Generate a sub control flow graph of instruction addresses based on self.graph

**Parameters**
**ins_addrs** (*iterable*) – A collection of instruction addresses that should be included in the subgraph.

**Return networkx.DiGraph**
A subgraph.

**instruction_size**(*insn_addr*)

Get the size of the instruction specified by *insn_addr*.

**Parameters**
**insn_addr** (*int*) – Address of the instruction

**Return int**
Size of the instruction in bytes, or None if the instruction is not found.

**addr**

**bp_on_stack**

**evicted**

**meta_only**

**normalized**

**previous_names**

**ran_cca**

**retaddr_on_stack**

**sp_delta**

**tags**

**addr_to_instruction_addr**(*addr*)

Obtain the address of the instruction that covers @addr.

**Parameters**
**addr** (*int*) – An address.

**Returns**
Address of the instruction that covers @addr, or None if this addr is not covered by any instruction of this function.

**Return type**
int or None

**dbg_print**()

Returns a representation of the list of basic blocks in this function.

**dbg_draw**(*filename*)

Draw the graph and save it to a PNG file.

**property arguments**

**property has_return**

**property callable**

**normalize**()

Make sure all basic blocks in the transition graph of this function do not overlap. You will end up with a CFG that IDA Pro generates.

This method does not touch the CFG result. You may call CFG{Emulated, Fast}.normalize() for that matter.

**Returns**
None

**find_declaration**(*ignore_binary_name=False*, *binary_name_hint=None*)

Find the most likely function declaration from the embedded collection of prototypes, set it to self.prototype, and update self.calling_convention with the declaration.

**Parameters**

- **ignore_binary_name** (bool) – Do not rely on the executable or library where the function belongs to determine its source library. This is useful when working on statically linked binaries (because all functions will belong to the main executable). We will search for all libraries in angr to find the first declaration match.
- **binary_name_hint** (str | None) – Substring of the library name where this function might be originally coming from. Useful for FLIRT-identified functions in statically linked binaries.

**Return type**
bool

**Returns**
True if a declaration is found and self.prototype and self.calling_convention are updated. False if we fail to find a matching function declaration, in which case self.prototype or self.calling_convention will be kept untouched.

**is_rust_function**()

Determines if the function name follows Rust mangling conventions.

**property demangled_name**

**property short_name**

**get_unambiguous_name**(*display_name=None*)

Get a disambiguated function name.

**Parameters**
**display_name** (str | None) – Name to display, otherwise the function name.

**Return type**
str

**Returns**

The function name in one of the following forms:

- ::<name> when the function binary is the main object.
- ::<obj>::<name> when the function binary is not the main object.
- ::<addr>::<name> when the function binary is an unnamed non-main object, or when multiple functions with the same name are defined in the function binary.

**apply_definition**(*definition*, *calling_convention=None*)

**Return type**
None

**Parameters**

- **definition** (*str*)
- **calling_convention** (SimCC | type[SimCC] | *None*)

**functions_reachable**()

**Return type**
set[*Function*]

**Returns**
The set of all functions that can be reached from the function represented by self.

**holes**(*min_size=8*)

Find the number of non-consecutive areas in the function that are at least *min_size* bytes large.

**Return type**
int

**Parameters**
**min_size** (*int*)

**copy**()

**pp**(***kwargs*)

Pretty-print the function disassembly.

**class** angr.knowledge_plugins.functions.**FunctionManager**

Bases: *KnowledgeBasePlugin*, Mapping[K, *Function*], Generic[K]

When cache_limit is set, the FunctionManager uses a SpillingFunctionDict that implements an LRU cache keeping only the most recently accessed N functions in memory, spilling others to an LMDB database on disk. This allows working with binaries that have more functions than can fit in memory.

**Parameters**
**cache_limit** (int | None) – Maximum number of functions to keep in memory. None means unlimited (no eviction). Default is None.

**__init__**(*kb*, *cache_limit=None*)

**Parameters**

- **kb** (KnowledgeBase)
- **cache_limit** (*int | None*)

**copy**()

**clear**()

**get_default_cache_limit**(*max_limit=5000*)

Get the default function cache limit based on the size of the binary.

**Return type**
int | None

**Returns**
The default cache limit; None means unlimited.

**Parameters**
**max_limit** (*int*)

**is_plt_cached**(*addr*)

**Return type**
bool

**Parameters**
**addr** (*int*)

**get_binary_name_cached**(*addr*)

**Return type**
str | None

**Parameters**
**addr** (*int*)

**function_name_changed**(*addr*, *old_name*, *new_name*)

Notify the FunctionManager that a function's name has changed.

**Parameters**

- **addr** (K) – Address of the function.
- **old_name** (str | None) – Old name of the function, or None if there is no old name.
- **new_name** (str) – New name of the function.

**Return type**
None

**get_by_addr**(*addr*, *meta_only=False*)

**Return type**
*Function*

**Parameters**
**meta_only** (*bool*)

**get_by_name**(*name*, *check_previous_names=False*)

**Return type**
Generator[*Function*]

**Parameters**

- **name** (*str*)
- **check_previous_names** (*bool*)

**get_addrs_by_name**(*name*, *check_previous_names=False*)

**Return type**
set[int]

**Parameters**

- **name** (*str*)
- **check_previous_names** (*bool*)

**contains_addr**(*addr*)

Decide if an address is handled by the function manager.

Note: this function is non-conformant with python programming idioms, but its needed for performance reasons.

**Parameters**
**addr** (*int*) – Address of the function.

**ceiling_addr**(*addr*)

Return the function who has the least address that is greater than or equal to *addr*.

**Parameters**
**addr** (K) – The address to query.

**Return type**
Optional[K]

**Returns**
A Function instance, or None if there is no other function after *addr*.

**ceiling_func**(*addr*)

Return the function who has the least address that is greater than or equal to *addr*.

**Parameters**
**addr** (*int*) – The address to query.

**Return type**
*Function* | None

**Returns**
A Function instance, or None if there is no other function after *addr*.

**floor_addr**(*addr*)

Return the function who has the greatest address that is less than or equal to *addr*.

**Parameters**
**addr** (K) – The address to query.

**Return type**
Optional[K]

**Returns**
An address, or None if there is no other function before *addr*.

**floor_func**(*addr*)

Return the function who has the greatest address that is less than or equal to *addr*.

**Parameters**
**addr** (*int*) – The address to query.

**Returns**
A Function instance, or None if there is no other function before *addr*.

**Return type**
*Function* or None

**query**(*query*, *check_previous_names=False*)

Query for a function using selectors to disambiguate. Supported variations:

::<name> Function <name> in the main object ::<addr>::<name> Function <name> at <addr> ::<obj>::<name> Function <name> in <obj>

**Return type**
*Function* | None

**Parameters**

- **query** (*str*)
- **check_previous_names** (*bool*)

**function**(*addr=None*, *name=None*, *check_previous_names=False*, *create=False*, *syscall=False*, *plt=None*)

Get a function object from the function manager.

Pass either *addr* or *name* with the appropriate values.

**Parameters**

- **addr** (Optional[K]) – Address of the function.
- **name** (str | None) – Name of the function.

- **create** (bool) – Whether to create the function or not if the function does not exist.
- **syscall** (bool) – True to create the function as a syscall, False otherwise.
- **plt** (bool | None) – True to find the PLT stub, False to find a non-PLT stub, None to disable this restriction.
- **check_previous_names** (*bool*)

**Returns**
The Function instance, or None if the function is not found and create is False.

**Return type**
*Function* | None

**dbg_draw**(*prefix='dbg_function_'*)

**rebuild_callgraph**()

**set_function_returning**(*addr*, *v*)

**Return type**
None

**Parameters**

- **addr** (*K*)
- **v** (*bool | None*)

**nonreturning_func_addrs**()

Yield all non-returning function addresses.

**Return type**
Generator[int]

**unknown_returning_func_addrs**()

Yield all function addresses with unknown returning status.

**Return type**
Generator[int]

**is_func_nonreturning**(*addr*)

Check if a function is non-returning.

**Parameters**
**addr** (K) – Address of the function.

**Return type**
bool

**Returns**
True if non-returning, False if returning or unknown.

**is_func_returning_unknown**(*addr*)

Check if a function's returning status is unknown.

**Parameters**
**addr** (K) – Address of the function.

**Return type**
bool

**Returns**
True if returning status is unknown, False otherwise.

`get_func_block_count`(*addr*)

Get the number of blocks in a function.

**Parameters**
**addr** (K) – Address of the function.

**Return type**
int | None

**Returns**
Number of blocks, or None if unknown.

`set_func_block_count`(*addr*, *count*)

Set the number of blocks in a function.

**Parameters**

- **addr** (K) – Address of the function.
- **count** (int) – Number of blocks.

**Return type**
None

**Returns**
None

`get_func_addr_with_block_count`(*block_count*)

Get the addresses of all functions that have exactly `block_count` blocks.

**Parameters**
**block_count** (int) – The number of blocks to match.

**Return type**
set[K]

**Returns**
The set of matching function addresses.

`get_func_name`(*addr*)

Get the name of a function without loading the (possibly spilled) Function object.

**Parameters**
**addr** (K) – Address of the function.

**Return type**
str | None

**Returns**
The function's name, or None if unknown.

`get_from_signature`(*addr*)

Get the `from_signature` value of a function without loading the (possibly spilled) Function object.

**Parameters**
**addr** (K) – Address of the function.

**Return type**
str | None

**Returns**
The function's `from_signature` value (e.g. `"flirt"`), or None.

`set_from_signature`(*addr*, *from_signature*)

Update the cached `from_signature` value for a function. Called by Function.from_signature's setter.

**Parameters**

- **addr** (K) – Address of the function.
- **from_signature** (`str` | `None`) – The new `from_signature` value.

**Return type**
`None`

**Returns**
None

`get_all_funcaddrs_from_signature`(*from_signature='flirt'*)

Get the addresses of all functions whose `from_signature` matches, without loading any Function object.

**Parameters**
**from_signature** (`str`) – The `from_signature` value to match (default `"flirt"`).

**Return type**
`set`[K]

**Returns**
The set of matching function addresses.

`get_key_func_addrs`(*func_type*)

**Return type**
`set`[K]

**Parameters**
**func_type** (*str*)

`get_key_func_type_and_addrs`()

Get all cached key functions grouped by key-function type (e.g. `"alloca_probe"`, `"jmp_rax"`).

**Return type**
`dict`[`str`, `set`[K]]

**Returns**
A mapping from key-function type to the set of function addresses of that type.

`add_key_func_addr`(*func_type*, *addr*)

**Return type**
`None`

**Parameters**

- **func_type** (*str*)
- **addr** (*K*)

`index_key_func_addrs`(*func*)

Record every key-function flag that `func.info` carries in the key-function address cache.

**Return type**
`None`

**Parameters**
**func** (Function)

**property cache_limit: int | None**

Get the maximum number of functions to keep in memory. None means unlimited (no eviction).

**Setter accepts**
int

**property cached_function_count: int**

Return the number of functions currently in memory.

**property spilled_function_count: int**

Return the number of functions currently spilled to LMDB.

**property total_function_count: int**

Return the total number of functions (in memory + spilled).

**class** angr.knowledge_plugins.functions.**PrototypeSource**

Bases: int, Enum

An enumeration to represent the source of a function prototype. The values are ordered by certainty, with higher values indicating more certainty.

**NONE = 0**

**GUESSED = 1**

**CCA_LOW = 2**

**CALLSITE_LOW = 3**

### angr.knowledge_plugins.functions.function

angr.knowledge_plugins.functions.function.**dirty_func**(*func*)

**class** angr.knowledge_plugins.functions.function.**PrototypeSource**

Bases: int, Enum

An enumeration to represent the source of a function prototype. The values are ordered by certainty, with higher values indicating more certainty.

**NONE = 0**

**GUESSED = 1**

**CCA_LOW = 2**

**CALLSITE_LOW = 3**

**CALLSITE_DECOMPILER = 6**

**CCA_DECOMPILER = 20**

**SIMPROC = 21**

**SIGNATURES = 25**

**USER = 100**

**__new__**(*value*)

**class** angr.knowledge_plugins.functions.function.**FunctionInfo**

Bases: UserDict

A dictionary that updates the .dirty field of the Function object when modified.

**__init__**(*func*)

**Parameters**
**func** (Function)

**copy**(*owner*)

**Return type**
*FunctionInfo*

**Parameters**
**owner** (Function)

**to_json**()

**Return type**
str

**classmethod from_json**(*json_str*, *owner*)

**Return type**
*FunctionInfo*

**Parameters**

- **json_str** (*str*)
- **owner** (Function)

**class** angr.knowledge_plugins.functions.function.**Function**

Bases: *Serializable*

A representation of a function and various information about it.

**Variables**

- **meta_only** – Whether this function only contains meta-information and in read-only mode.
- **_dirty** – Whether this function has been modified since last serialization.
- **evicted** – Whether this function has been evicted from FunctionManager to external storage.

**__init__**(*function_manager*, *addr*, *name=None*, *syscall=None*, *is_simprocedure=None*, *binary_name=None*, *is_plt=None*, *returning=None*, *alignment=False*, *calling_convention=None*, *prototype=None*, *prototype_libname=None*, *prototype_source=None*, *is_prototype_guessed=True*)

Function constructor. If the optional parameters are not provided, they will be automatically determined upon the creation of a Function object.

**Parameters**

- **addr** (int) – The address of the function.
- **name** (*str*) – The name of the function.
- **syscall** (*bool*) – Whether this function is a syscall or not.
- **is_simprocedure** (bool | None) – Whether this function is a SimProcedure or not.
- **binary_name** (*str*) – Name of the binary where this function is.
- **is_plt** (bool | None) – If this function is a PLT entry.
- **returning** (*bool*) – If this function returns.
- **alignment** (*bool*) – If this function acts as an alignment filler. Such functions usually only contain nops.
- **function_manager** (FunctionManager | *None*)
- **calling_convention** (SimCC | *None*)
- **prototype** (SimTypeFunction | *None*)
- **prototype_libname** (*str* | *None*)
- **prototype_source** (PrototypeSource | *None*)
- **is_prototype_guessed** (*bool*)

**is_default_name**

**binary_name**

**property name**

**property from_signature: str | None**

**property project: *Project* | None**

**property returning**

**property calling_convention: *SimCC* | None**

**property prototypes: dict[str, *SimTypeFunction* | None]**

A snapshot of every flavor's prototype, keyed by decompilation flavor. Write through set_prototype(); the default-flavor entry is also exposed as .prototype.

**property prototype_sources: dict[str, *PrototypeSource*]**

A snapshot of every flavor's prototype source; the default-flavor entry is also exposed as .prototype_source.

property prototype: *SimTypeFunction* | None

get_prototype(*flavor*)

The prototype a decompilation of the given flavor should use: the flavor's own entry, or the C prototype when the flavor has none. The C flavor never falls back to another flavor.

**Return type**
*SimTypeFunction* | None

**Parameters**
**flavor** (*str | None*)

has_prototype_for_flavor(*flavor*)

Whether the flavor has its own entry (as opposed to falling back to the C prototype).

**Return type**
bool

**Parameters**
**flavor** (*str | None*)

uses_default_prototype_for(*flavor*)

Whether get_prototype(flavor) is the default flavor's (C) prototype, e.g., to dereference it by library.

**Return type**
bool

**Parameters**
**flavor** (*str | None*)

get_prototype_source(*flavor*)

The source of the prototype get_prototype(flavor) returns.

**Return type**
*PrototypeSource*

**Parameters**
**flavor** (*str | None*)

set_prototype(*flavor*, *proto*, *source=None*)

Set the prototype of a flavor. A flavor's first entry starts with the source of the prototype it used to fall back to (the C one) unless `source` is given.

**Return type**
None

**Parameters**

- **flavor** (*str | None*)
- **proto** (SimTypeFunction | *None*)
- **source** (PrototypeSource | *None*)

set_prototype_source(*flavor*, *source*)

Set the source of a flavor's prototype; a flavor without an entry gets one that falls back to C's.

**Return type**
None

**Parameters**

- **flavor** (*str | None*)

- **source** (PrototypeSource)

**clear_prototype**(*flavor*)

Drop a flavor's own entry so that it falls back to the C prototype; clearing C sets it to None.

**Return type**
None

**Parameters**
**flavor** (*str | None*)

**property prototype_libname**

**Setter accepts**
str | None

**property is_prototype_guessed: bool**

**is_prototype_guessed_for**(*flavor*)

**Return type**
bool

**Parameters**
**flavor** (*str | None*)

**property is_prototype_groundtruth: bool**

True if the prototype comes from outside of the decompiler (SimProcedures, signatures, or the user) and may be fed back into type inference as ground truth. Prototypes inferred by the decompiler itself are excluded so that re-decompiling a function does not freeze its own earlier guess.

**is_prototype_groundtruth_for**(*flavor*)

is_prototype_groundtruth for the prototype get_prototype(flavor) returns.

**Return type**
bool

**Parameters**
**flavor** (*str | None*)

**property prototype_source: *PrototypeSource***

**property info: *FunctionInfo***

**Setter accepts**
*FunctionInfo* | dict

**property is_plt: bool**

**property is_simprocedure: bool**

**property is_syscall: bool**

**property is_alignment: bool**

**transition_out_edges**(*node*)

(successor, edge data) pairs of a node, in the order of `transition_graph.out_edges(node, data=True)`, without building the networkx transition graph when it does not exist yet.

**Return type**
list[tuple[*CodeNode*, Mapping[str, Any]]]

**Parameters**
**node** (CodeNode)

`transition_in_edges`(*node*)

(predecessor, edge data) pairs of a node, in the order of `transition_graph.in_edges(node, data=True)`, without building the networkx transition graph when it does not exist yet.

**Return type**
`list`[`tuple`[*CodeNode*, `Mapping`[`str`, `Any`]]]

**Parameters**
**node** (CodeNode)

`has_node`(*node*)

**Return type**
`bool`

**Parameters**
**node** (CodeNode)

`set_edge_outside`(*src*, *dst*, *outside*)

**Return type**
`None`

**Parameters**

- **src** (CodeNode)
- **dst** (CodeNode)
- **outside** (*bool*)

`add_graph_node`(*node*)

Add a node to the transition graph without registering it as a local block.

**Return type**
`None`

**Parameters**
**node** (CodeNode)

`add_graph_edge`(*src*, *dst*, *type=None*, *outside=None*, *ins_addr=<object object>*, *stmt_idx=<object object>*, *confirmed=None*)

Add or update an edge of the transition graph.

**Return type**
`None`

**Parameters**

- **src** (CodeNode)
- **dst** (CodeNode)
- **type** (*str | None*)
- **outside** (*bool | None*)
- **ins_addr** (*int | None*)
- **stmt_idx** (*int | None*)
- **confirmed** (*bool | None*)

**remove_graph_node**(*node*)

Remove a node and its edges from the transition graph.

**Return type**
None

**Parameters**
**node** (CodeNode)

**set_edge_confirmed**(*src*, *dst*, *confirmed*)

**Return type**
None

**Parameters**

- **src** (CodeNode)
- **dst** (CodeNode)
- **confirmed** (*bool*)

**property transition_graph:** *TransitionGraph*

A read-only networkx view of the transition graph, created on-demand and kept in sync with the Function's updates.

**property startpoint:** *CodeNode* | None

**property blocks**

An iterator of all local blocks in the current function.

**Returns**
angr.lifter.Block instances.

**property code_nodes:** dict[int, *CodeNode*]

**property cyclomatic_complexity**

The cyclomatic complexity of the function.

Cyclomatic complexity is a software metric used to indicate the complexity of a program. It is a quantitative measure of the number of linearly independent paths through a program's source code. It is computed using the formula: M = E - N + 2P, where E = the number of edges in the graph, N = the number of nodes in the graph, P = the number of connected components.

The cyclomatic complexity value is lazily computed and cached for future use. Initially this value is None until it is computed for the first time

**Returns**
The cyclomatic complexity of the function.

**Return type**
int

**property xrefs:** Iterator[*XRef*]

An iterator of all xrefs of the current function.

**Returns**
angr.knowledge_plugins.xrefs.xref.XRef instances.

**property block_addrs**

An iterator of all local block addresses in the current function.

**Returns**
block addresses.

**property block_addrs_set**

Return a set of block addresses for a better performance of inclusion tests.

**Returns**
A set of block addresses.

**Return type**
set

**get_block**(*addr*, *size=None*, *byte_string=None*)

Getting a block out of the current function.

**Parameters**

- **addr** (int) – The address of the block.
- **size** (int | None) – The size of the block. This is optional. If not provided, angr will load
- **byte_string** (bytes | None)

**Returns**

**get_block_size**(*addr*)

**Return type**
int | None

**Parameters**
**addr** (*int*)

**property nodes: Iterable[*CodeNode*]**

**get_node**(*addr*)

**Return type**
*BlockNode* | None

**property has_unresolved_jumps**

**property has_unresolved_calls**

**property operations**

All of the operations that are done by this functions.

**property code_constants**

All of the constants that are used by this functions's code.

**classmethod parse_from_cmessage**(*cmsg*, ***kwargs*)

**Parameters**
**cmsg**

**Return Function**
The function instantiated out of the cmsg data.

**string_references**(*minimum_length=2*)

All of the constant string references used by this function.

**Parameters**
**minimum_length** – The minimum length of strings to find (default is 1)

**Returns**
A generator yielding tuples of (address, string) where is address is the location of the string in memory.

**property local_runtime_values**
Tries to find all runtime values of this function which do not come from inputs. These values are generated by starting from a blank state and reanalyzing the basic blocks once each. Function calls are skipped, and back edges are never taken so these values are often unreliable, This function is good at finding simple constant addresses which the function will use or calculate.

**Returns**
a set of constants

**property num_arguments**

**property endpoints: list[*CodeNode*]**

**property endpoints_with_type: defaultdict[str, set[*CodeNode*]]**

**property ret_sites: list[*CodeNode*]**

**property jumpout_sites: list[*CodeNode*]**

**property retout_sites: list[*CodeNode*]**

**property callout_sites: list[*CodeNode*]**

**property size**

**property binary**
Get the object this function belongs to. :return: The object this function belongs to.

**property offset: int**
the function's binary offset (i.e., non-rebased address)

**Type**
return

**property symbol: Symbol | None**
the function's Symbol, if any

**Type**
return

**property pseudocode: str | None**
the function's pseudocode

**Type**
return

**property dirty: bool**

**mark_dirty**()

**Return type**
None

**add_jumpout_site**(*node*)
Add a custom jumpout site.

**Parameters**
**node** (*CodeNode*) – The address of the basic block that control flow leaves during this transition.

**Returns**
None

`add_retout_site`(*node*)

Add a custom retout site.

Retout (returning to outside of the function) sites are very rare. It mostly occurs during CFG recovery when we incorrectly identify the beginning of a function in the first iteration, and then correctly identify that function later in the same iteration (function alignments can lead to this bizarre case). We will mark all edges going out of the header of that function as a outside edge, because all successors now belong to the incorrectly-identified function. This identification error will be fixed in the second iteration of CFG recovery. However, we still want to keep track of jumpouts/retouts during the first iteration so other logic in CFG recovery still work.

**Parameters**
**node** (*CodeNode*) – The address of the basic block that control flow leaves the current function after a call.

**Returns**
None

`clear_transition_graph`()

`confirm_fakeret`(*src*, *dst*)

`transit_to`(*from_node*, *to_node*, *outside=False*, *ins_addr=None*, *stmt_idx=None*, *is_exception=False*, *update_func_block_count=True*)

Registers an edge between basic blocks in this function's transition graph. Arguments are CodeNode objects.

**Parameters**

- **from_node** (*CodeNode*) – The address of the basic block that control flow leaves during this transition.
- **to_node** – The address of the basic block that control flow enters during this transition.
- **outside** (*bool*) – If this is a transition to another function, e.g. tail call optimization
- **update_func_block_count** (*bool*)

**Returns**
None

`call_to`(*from_node*, *to_func*, *ret_node*, *stmt_idx=None*, *ins_addr=None*, *return_to_outside=False*, *syscall=False*, *update_func_block_count=True*)

Registers an edge between the caller basic block and callee function.

**Parameters**

- **from_node** (*angr.knowledge.CodeNode*) – The basic block that control flow leaves during the transition.
- **to_func** (*FuncNode* | *HookNode*) – The function that we are calling, represented as a FuncNode.
- **ret_node** (*angr.knowledge.CodeNode or None*) – The basic block that control flow should return to after the function call.

- **stmt_idx** (*int, str or None*) – Statement ID of this call.
- **ins_addr** (*int or None*) – Instruction address of this call.
- **syscall** (*bool*)
- **update_func_block_count** (*bool*)

**fakeret_to**(*from_node*, *to_node*, *confirmed=None*, *to_outside=False*, *update_func_block_count=True*)

**Parameters**
**update_func_block_count** (*bool*)

**remove_fakeret**(*from_node*, *to_node*)

**remove_edge**(*from_node*, *to_node*)

**Return type**
None

**Parameters**

- **from_node** (CodeNode)
- **to_node** (CodeNode)

**return_from_call**(*from_func*, *to_node*, *to_outside=False*, *confirm_fakeret=True*)

**Parameters**

- **from_func** (FuncNode | HookNode)
- **confirm_fakeret** (*bool*)

**update_func_block_count**()

Update the cached block count of this function in the function manager.

**Return type**
None

**register**(*is_local*, *node*, *update_func_block_count=True*)

Register a node with the function and return its ID. The first object that is registered for a fresh ID becomes the ID's canonical CodeNode object.

**Return type**
int

**Parameters**

- **is_local** (*bool*)
- **node** (CodeNode)
- **update_func_block_count** (*bool*)

**register_node**(*is_local*, *node*, *update_func_block_count=True*)

**Return type**
*CodeNode*

**Parameters**

- **is_local** (*bool*)
- **node** (CodeNode)
- **update_func_block_count** (*bool*)

**add_return_site**(*return_site*)

Registers a basic block as a site for control flow to return from this function.

**Parameters**
**return_site** (*CodeNode*) – The block node that ends with a return.

**add_call_site**(*call_site_addr*, *call_target_addr*, *retn_addr*)

Registers a basic block as calling a function and returning somewhere.

**Parameters**

- **call_site_addr** – The address of a basic block that ends in a call.
- **call_target_addr** – The address of the target of said call.
- **retn_addr** – The address that said call will return to.

**add_endpoint**(*endpoint_node*, *sort*)

Registers an endpoint with a type of *sort*. The type can be one of the following: - call: calling a function that does not return - return: returning from the current function - transition: a jump/branch targeting a different function

It is possible for a block to act as two different sorts of endpoints. For example, consider the following block:

.text:0000000000024350 mov eax, 1 .text:0000000000024355 lock xadd [rdi+4], eax .text:000000000002435A retn

**VEX code:**
00 | —— IMark(0x424350, 5, 0) —— 01 | PUT(rax) = 0x0000000000000001 02 | PUT(rip) = 0x0000000000424355 03 | —— IMark(0x424355, 5, 0) —— 04 | t11 = GET:I64(rdi) 05 | t10 = Add64(t11,0x0000000000000004) 06 | t0 = LDle:I32(t10) 07 | t2 = Add32(t0,0x00000001) 08 | t(4,4294967295) = CASle(t10 :: (t0,None)->(t2,None)) 09 | t14 = CasCmpNE32(t4,t0) 10 | if (t14) { PUT(rip) = 0x424355; Ijk_Boring } 11 | PUT(cc_op) = 0x0000000000000003 12 | t15 = 32Uto64(t0) 13 | PUT(cc_dep1) = t15 14 | PUT(cc_dep2) = 0x0000000000000001 15 | t17 = 32Uto64(t0) 16 | PUT(rax) = t17 17 | PUT(rip) = 0x000000000042435a 18 | —— IMark(0x42435a, 1, 0) —— 19 | t6 = GET:I64(rsp) 20 | t7 = LDle:I64(t6) 21 | t8 = Add64(t6,0x0000000000000008) 22 | PUT(rsp) = t8 23 | t18 = Sub64(t8,0x0000000000000080) 24 | ====== AbiHint(0xt18, 128, t7) ====== NEXT: PUT(rip) = t7; Ijk_Ret

This block acts as both a return endpoint and a transition endpoint (transitioning to 0x424355).

**Parameters**

- **endpoint_node** – The endpoint node.
- **sort** – Type of the endpoint.

**Returns**
None

**mark_nonreturning_calls_endpoints**()

Iterate through all call edges in transition graph. For each call a non-returning function, mark the source basic block as an endpoint.

This method should only be executed once all functions are recovered and analyzed by CFG recovery, so we know whether each function returns or not.

**Returns**
None

**property call_sites:** dict[int, tuple[int | None, int | None]]

**call_edge_addrs**()

(call-site block address, callee address) of every call edge, in transition-graph order. Unlike call_sites, a block with several call targets contributes one pair per target.

**Return type**
list[tuple[int, int]]

**jumpout_targets**()

(jump-out site block address, target address, branch instruction address) of every transition that leaves this function, such as a tail jump. The instruction address is None when the CFG did not record it.

**Return type**
list[tuple[int, int, int | None]]

**unconfirmed_fakeret_edges**()

Fake-return edges that have not been confirmed by a return of the callee, in transition-graph order.

**Return type**
list[tuple[*CodeNode*, *CodeNode*]]

**outgoing_function_targets**()

Addresses of the functions this function calls or jumps out to.

**Return type**
list[int]

**get_call_sites**()

Gets a list of all the basic blocks that end in calls.

**Return type**
Iterable[int]

**Returns**
A view of the addresses of the blocks that end in calls.

**get_call_target**(*callsite_addr*)

Get the target of a call.

**Parameters**
**callsite_addr** – The address of a basic block that ends in a call.

**Returns**
The target of said call, or None if callsite_addr is not a callsite.

**get_call_return**(*callsite_addr*)

Get the hypothetical return address of a call.

**Parameters**
**callsite_addr** – The address of the basic block that ends in a call.

**Returns**
The likely return target of said call, or None if callsite_addr is not a callsite.

**property graph:** *TransitionGraph*

Get a local transition graph. A local transition graph is a transition graph that only contains nodes that belong to the current function. All edges, except for the edges going out from the current function or coming from outside the current function, are included.

The generated graph is a read-only view cached in self._local_transition_graph.

**Returns**
A local transition graph.

**graph_ex**(*exception_edges=True*)

Get a local transition graph with a custom configuration. A local transition graph is a transition graph that only contains nodes that belong to the current function. This method allows user to include certain types of edges and nodes, such as exception edges.

The generated graph is not cached. It is a mutable copy.

**Parameters**
**exception_edges** (*bool*) – Should exception edges and the nodes that are only reachable through exception edges be kept.

**Return type**
networkx.DiGraph[CodeNode]

**Returns**
A local transition graph with a special configuration.

**transition_graph_ex**(*exception_edges=True*)

Get a transition graph with a custom configuration. This method allows user to exclude certain types of edges together with the nodes that are only reachable through such edges, such as exception edges.

The generated graph is not cached.

**Parameters**
**exception_edges** (*bool*) – Should exception edges and the nodes that are only reachable through exception edges be kept.

**Returns**
A local transition graph with a special configuration.

**Return type**
networkx.DiGraph

**subgraph**(*ins_addrs*)

Generate a sub control flow graph of instruction addresses based on self.graph

**Parameters**
**ins_addrs** (*iterable*) – A collection of instruction addresses that should be included in the subgraph.

**Return networkx.DiGraph**
A subgraph.

**instruction_size**(*insn_addr*)

Get the size of the instruction specified by *insn_addr*.

**Parameters**
**insn_addr** (*int*) – Address of the instruction

**Return int**
Size of the instruction in bytes, or None if the instruction is not found.

**addr**

**bp_on_stack**

**evicted**

**meta_only**

**normalized**

**previous_names**

**ran_cca**

**retaddr_on_stack**

**sp_delta**

**tags**

**addr_to_instruction_addr**(*addr*)

Obtain the address of the instruction that covers @addr.

**Parameters**
**addr** (*int*) – An address.

**Returns**
Address of the instruction that covers @addr, or None if this addr is not covered by any instruction of this function.

**Return type**
int or None

**dbg_print**()

Returns a representation of the list of basic blocks in this function.

**dbg_draw**(*filename*)

Draw the graph and save it to a PNG file.

**property arguments**

**property has_return**

**property callable**

**normalize**()

Make sure all basic blocks in the transition graph of this function do not overlap. You will end up with a CFG that IDA Pro generates.

This method does not touch the CFG result. You may call CFG{Emulated, Fast}.normalize() for that matter.

**Returns**
None

**find_declaration**(*ignore_binary_name=False*, *binary_name_hint=None*)

Find the most likely function declaration from the embedded collection of prototypes, set it to self.prototype, and update self.calling_convention with the declaration.

**Parameters**

- **ignore_binary_name** (bool) – Do not rely on the executable or library where the function belongs to determine its source library. This is useful when working on statically linked binaries (because all functions will belong to the main executable). We will search for all libraries in angr to find the first declaration match.
- **binary_name_hint** (str | None) – Substring of the library name where this function might be originally coming from. Useful for FLIRT-identified functions in statically linked binaries.

**Return type**
bool

**Returns**
True if a declaration is found and self.prototype and self.calling_convention are updated. False if we fail to find a matching function declaration, in which case self.prototype or self.calling_convention will be kept untouched.

**is_rust_function**()

Determines if the function name follows Rust mangling conventions.

**property demangled_name**

**property short_name**

**get_unambiguous_name**(*display_name=None*)

Get a disambiguated function name.

**Parameters**
**display_name** (str | None) – Name to display, otherwise the function name.

**Return type**
str

**Returns**

The function name in one of the following forms:

- ::<name> when the function binary is the main object.
- ::<obj>::<name> when the function binary is not the main object.
- ::<addr>::<name> when the function binary is an unnamed non-main object, or when multiple functions with the same name are defined in the function binary.

**apply_definition**(*definition*, *calling_convention=None*)

**Return type**
None

**Parameters**

- **definition** (*str*)
- **calling_convention** (SimCC | type[SimCC] | *None*)

**functions_reachable**()

**Return type**
set[*Function*]

**Returns**
The set of all functions that can be reached from the function represented by self.

**holes**(*min_size=8*)

Find the number of non-consecutive areas in the function that are at least *min_size* bytes large.

**Return type**
int

**Parameters**
**min_size** (*int*)

**copy**()

**pp**(***kwargs*)

Pretty-print the function disassembly.

### angr.knowledge_plugins.functions.function_manager

**class** angr.knowledge_plugins.functions.function_manager.**FunctionDictBase**

Bases: Generic[K]

Base class for FunctionDict and SpillingFunctionDict.

**__init__**(*backref*, *key_types=<class 'int'>*)

**Parameters**

- **backref** (FunctionManager[K] | None)
- **key_types** (type)

**floor_addr**(*addr*)

**Parameters**
**addr** (*K*)

**ceiling_addr**(*addr*)

**items**()

**get**(*addr*, *default=<object object>*, */*, *meta_only=False*)

**Overloads**

- **key** (K), **default** (None) = None, /, **meta_only** (bool) = False →
- **key** (K), **default** (), /, **meta_only** (bool) = False →
- **key** (K), **default** (T), /, **meta_only** (bool) = False → Union[*Function*, T]

**Parameters**

- **addr** (*K*)
- **meta_only** (*bool*)

**irange**(*minimum=None*, *maximum=None*, *inclusive=(True, True)*, *reverse=False*)

**class** angr.knowledge_plugins.functions.function_manager.**FunctionDict**

Bases: SortedDict[, *Function*], *FunctionDictBase*[]

FunctionDict is a dict where the keys are function starting addresses and map to the associated Function.

**floor_addr**(*addr*)

**Parameters**
**addr** (*K*)

**ceiling_addr**(*addr*)

**class** angr.knowledge_plugins.functions.function_manager.**SpillingFunctionDict**

Bases: UserDict[, *Function*], *FunctionDictBase*[]

SpillingFunctionDict extends FunctionDict with LRU caching and LMDB spilling. This class keeps only the most recently accessed N functions in memory, spilling others to an LMDB database on disk.

SpillingFunctionDict also keeps a cache of meta-only Function objects that do not have graph or block information. These meta-only Function objects are read-only and may become stale if the full Function is later loaded and updated. Therefore, please be extremely cautious when using these meta-only Function objects.

SpillingFunctionDict._load_from_lmdb() does not support reentry. If a function being loaded from LMDB triggers another load from LMDB, the inner load will raise a RuntimeError.

A Function instance becomes "dirty" (Function.dirty) if it has been modified since being loaded from LMDB. Dirty functions are always saved back to LMDB when evicted, while clean functions are skipped during eviction.

A Function instance becomes "evicted" (Function.evicted) and stale if it has been spilled to LMDB. An evicted Function instance may not reflect the most recent state of the function, and any changes to an evicted Function instance will not be saved to LMDB. Therefore, if SpillingFunctionDict is in use, it is advised not to hold a Function instance for too long before using it.

**Variables**

- **cache_limit** – The maximum number of functions to keep in memory.
- **rtdb** (*RuntimeDb*) – A reference to the RuntimeDb knowledge base plugin.
- **_lru_order** (OrderedDict[K, None]) – An OrderedDict tracking the eviction order of cached functions.
- **_spilled_keys** (set[K]) – A set of function addresses that have been spilled to LMDB.
- **_db_batch_size** (int) – The number of functions that are evicted in a single batch.
- **_meta_func_cache** (LRUCache[K, *Function*]) – An LRU cache for meta-only Function objects.
- **_eviction_enabled** (bool) – A flag indicating whether eviction is currently enabled or not.

**__init__**(*backref*, *rtdb*, */*, *key_types=<class 'int'>*, *cache_limit=1000*, *db_batch_size=100*, ***kwargs*)

**Parameters**

- **backref** (FunctionManager*[K] | None*)
- **rtdb** (RuntimeDb)
- **key_types** (type)
- **cache_limit** (*int*)
- **db_batch_size** (*int*)

**copy**()

**Return type**
*SpillingFunctionDict*[K]

**clear**()

Clear all functions from memory and spilled storage.

**Return type**
None

**property cached_keys:** Generator[K]

**property cache_limit:** int

Get the maximum number of functions to keep in memory.

**property cached_count:** int

Return the number of functions currently in memory.

**property spilled_count: int**

Return the number of functions currently spilled to LMDB.

**property total_count: int**

Return the total number of functions (in memory + spilled).

**is_cached**(*addr*)

**Return type**
bool

**Parameters**
**addr** (*K*)

**bulk_import_serialized**(*items*)

Bulk-import already-serialized functions directly into the LMDB backing store and register them as spilled, without deserializing them. The serialized bytes must be serialized function_pb2.Function messages, i.e., the exact format that _save_to_lmdb() writes.

Imported functions are deserialized lazily upon first access, through the regular _load_from_lmdb() path.

**Parameters**
**items** (list[tuple[K, bytes]]) – A list of (address, serialized function bytes) tuples.

**Return type**
None

**export_serialized**()

Export all functions as serialized bytes, e.g., for dumping into an angr database.

Functions whose LMDB records are guaranteed to be current are copied directly from the LMDB backing store (in a single read transaction) without being deserialized and re-serialized. This applies to all spilled functions and to cached functions that are clean: a Function instance is only ever clean if it was deserialized from serialized bytes and has not been modified since (eviction relies on the same invariant to skip writing clean functions back to LMDB). Dirty functions, and functions whose LMDB record is missing, are serialized from their in-memory objects through the regular path.

**Return type**
list[tuple[K, bytes, bool]]

**Returns**
A list of (address, serialized function bytes, copied_from_lmdb) tuples, ordered by address.

**load_all_spilled**()

Load all spilled functions back into memory (disables eviction temporarily).

**Return type**
None

**evict_all_cached**()

Evict all cached functions to LMDB.

**Return type**
None

**class** angr.knowledge_plugins.functions.function_manager.**FunctionManager**

Bases: *KnowledgeBasePlugin*, Mapping[K, *Function*], Generic[K]

When cache_limit is set, the FunctionManager uses a SpillingFunctionDict that implements an LRU cache keeping only the most recently accessed N functions in memory, spilling others to an LMDB database on disk. This allows working with binaries that have more functions than can fit in memory.

**Parameters**
**cache_limit** (int | None) – Maximum number of functions to keep in memory. None means unlimited (no eviction). Default is None.

**__init__**(*kb*, *cache_limit=None*)

**Parameters**

- **kb** (KnowledgeBase)
- **cache_limit** (*int | None*)

**copy**()

**clear**()

**get_default_cache_limit**(*max_limit=5000*)

Get the default function cache limit based on the size of the binary.

**Return type**
int | None

**Returns**
The default cache limit; None means unlimited.

**Parameters**
**max_limit** (*int*)

**is_plt_cached**(*addr*)

**Return type**
bool

**Parameters**
**addr** (*int*)

**get_binary_name_cached**(*addr*)

**Return type**
str | None

**Parameters**
**addr** (*int*)

**function_name_changed**(*addr*, *old_name*, *new_name*)

Notify the FunctionManager that a function's name has changed.

**Parameters**

- **addr** (K) – Address of the function.
- **old_name** (str | None) – Old name of the function, or None if there is no old name.
- **new_name** (str) – New name of the function.

**Return type**
None

**get_by_addr**(*addr*, *meta_only=False*)

**Return type**
*Function*

**Parameters**
**meta_only** (*bool*)

get_by_name(*name*, *check_previous_names=False*)

**Return type**
Generator[*Function*]

**Parameters**

- **name** (*str*)
- **check_previous_names** (*bool*)

get_addrs_by_name(*name*, *check_previous_names=False*)

**Return type**
set[int]

**Parameters**

- **name** (*str*)
- **check_previous_names** (*bool*)

contains_addr(*addr*)

Decide if an address is handled by the function manager.

Note: this function is non-conformant with python programming idioms, but its needed for performance reasons.

**Parameters**
**addr** (*int*) – Address of the function.

ceiling_addr(*addr*)

Return the function who has the least address that is greater than or equal to *addr*.

**Parameters**
**addr** (K) – The address to query.

**Return type**
Optional[K]

**Returns**
A Function instance, or None if there is no other function after *addr*.

ceiling_func(*addr*)

Return the function who has the least address that is greater than or equal to *addr*.

**Parameters**
**addr** (*int*) – The address to query.

**Return type**
*Function* | None

**Returns**
A Function instance, or None if there is no other function after *addr*.

floor_addr(*addr*)

Return the function who has the greatest address that is less than or equal to *addr*.

**Parameters**
**addr** (K) – The address to query.

**Return type**
Optional[K]

**Returns**
An address, or None if there is no other function before *addr*.

**floor_func**(*addr*)

Return the function who has the greatest address that is less than or equal to *addr*.

**Parameters**
**addr** (*int*) – The address to query.

**Returns**
A Function instance, or None if there is no other function before *addr*.

**Return type**
*Function* or None

**query**(*query*, *check_previous_names=False*)

Query for a function using selectors to disambiguate. Supported variations:

::<name> Function <name> in the main object ::<addr>::<name> Function <name> at <addr> ::<obj>::<name> Function <name> in <obj>

**Return type**
*Function* | None

**Parameters**

- **query** (*str*)
- **check_previous_names** (*bool*)

**function**(*addr=None*, *name=None*, *check_previous_names=False*, *create=False*, *syscall=False*, *plt=None*)

Get a function object from the function manager.

Pass either *addr* or *name* with the appropriate values.

**Parameters**

- **addr** (Optional[K]) – Address of the function.
- **name** (str | None) – Name of the function.
- **create** (bool) – Whether to create the function or not if the function does not exist.
- **syscall** (bool) – True to create the function as a syscall, False otherwise.
- **plt** (bool | None) – True to find the PLT stub, False to find a non-PLT stub, None to disable this restriction.
- **check_previous_names** (*bool*)

**Returns**
The Function instance, or None if the function is not found and create is False.

**Return type**
*Function* | None

**dbg_draw**(*prefix='dbg_function_'*)

**rebuild_callgraph**()

**set_function_returning**(*addr*, *v*)

**Return type**
None

**Parameters**

- **addr** (*K*)
- **v** (*bool | None*)

**nonreturning_func_addrs**()

Yield all non-returning function addresses.

**Return type**
Generator[int]

**unknown_returning_func_addrs**()

Yield all function addresses with unknown returning status.

**Return type**
Generator[int]

**is_func_nonreturning**(*addr*)

Check if a function is non-returning.

**Parameters**
**addr** (K) – Address of the function.

**Return type**
bool

**Returns**
True if non-returning, False if returning or unknown.

**is_func_returning_unknown**(*addr*)

Check if a function's returning status is unknown.

**Parameters**
**addr** (K) – Address of the function.

**Return type**
bool

**Returns**
True if returning status is unknown, False otherwise.

**get_func_block_count**(*addr*)

Get the number of blocks in a function.

**Parameters**
**addr** (K) – Address of the function.

**Return type**
int | None

**Returns**
Number of blocks, or None if unknown.

**set_func_block_count**(*addr*, *count*)

Set the number of blocks in a function.

**Parameters**

- **addr** (K) – Address of the function.
- **count** (int) – Number of blocks.

**Return type**
None

**Returns**
None

`get_func_addr_with_block_count`(*block_count*)

Get the addresses of all functions that have exactly `block_count` blocks.

**Parameters**
**block_count** (int) – The number of blocks to match.

**Return type**
set[K]

**Returns**
The set of matching function addresses.

`get_func_name`(*addr*)

Get the name of a function without loading the (possibly spilled) Function object.

**Parameters**
**addr** (K) – Address of the function.

**Return type**
str | None

**Returns**
The function's name, or None if unknown.

`get_from_signature`(*addr*)

Get the `from_signature` value of a function without loading the (possibly spilled) Function object.

**Parameters**
**addr** (K) – Address of the function.

**Return type**
str | None

**Returns**
The function's `from_signature` value (e.g. `"flirt"`), or None.

`set_from_signature`(*addr*, *from_signature*)

Update the cached `from_signature` value for a function. Called by Function.from_signature's setter.

**Parameters**

- **addr** (K) – Address of the function.
- **from_signature** (str | None) – The new `from_signature` value.

**Return type**
None

**Returns**
None

`get_all_funcaddrs_from_signature`(*from_signature='flirt'*)

Get the addresses of all functions whose `from_signature` matches, without loading any Function object.

**Parameters**
**from_signature** (str) – The `from_signature` value to match (default `"flirt"`).

**Return type**
set[K]

**Returns**
The set of matching function addresses.

**get_key_func_addrs**(*func_type*)

**Return type**
set[K]

**Parameters**
**func_type** (*str*)

**get_key_func_type_and_addrs**()

Get all cached key functions grouped by key-function type (e.g. "alloca_probe", "jmp_rax").

**Return type**
dict[str, set[K]]

**Returns**
A mapping from key-function type to the set of function addresses of that type.

**add_key_func_addr**(*func_type*, *addr*)

**Return type**
None

**Parameters**

- **func_type** (*str*)
- **addr** (*K*)

**index_key_func_addrs**(*func*)

Record every key-function flag that func.info carries in the key-function address cache.

**Return type**
None

**Parameters**
**func** (Function)

**property cache_limit: int | None**

Get the maximum number of functions to keep in memory. None means unlimited (no eviction).

**Setter accepts**
int

**property cached_function_count: int**

Return the number of functions currently in memory.

**property spilled_function_count: int**

Return the number of functions currently spilled to LMDB.

**property total_function_count: int**

Return the total number of functions (in memory + spilled).

### angr.knowledge_plugins.functions.function_parser

**class** angr.knowledge_plugins.functions.function_parser.**CallingConventionSerializer**

Bases: object

Serialize/deserialize SimCC classes.

**static to_json**(*cc*)

**Return type**
dict

**Parameters**
**cc** (SimCC)

**static from_json**(*data*, *arch*)

**Return type**
*SimCC* | None

**Parameters**
**data** (*dict*)

**class** angr.knowledge_plugins.functions.function_parser.**FunctionParser**

Bases: object

The implementation of the serialization methods for the <Function> class.

**static serialize**(*function*)

:return :

**static local_block_addrs_from_cmsg**(*cmsg*)

Get the addresses of the local blocks of a serialized function without building the Function object.

**Return type**
set[int]

**static parse_from_cmsg**(*cmsg*, *function_manager=None*, *project=None*, *meta_only=False*)

**Parameters**

- **cmsg** – The data to instantiate the <Function> from.
- **meta_only** (*bool*)

**Return Function**

### angr.knowledge_plugins.functions.soot_function

**class** angr.knowledge_plugins.functions.soot_function.**SootFunction**

Bases: *Function*

A representation of a Soot function.

**__init__**(*function_manager*, *addr*, *name=None*, *syscall=None*)

Function constructor for Soot

**Parameters**

- **addr** – The address of the function.
- **name** – (Optional) The name of the function.
- **syscall** – (Optional) Whether this function is a syscall or not.

**register_node**(*is_local*, *node*, *update_func_block_count=True*)

**Parameters**

- **is_local** (*bool*)
- **update_func_block_count** (*bool*)

**property blocks**

An iterator of all local blocks in the current function.

**property code_nodes: dict[int, *CodeNode*]**

**property cyclomatic_complexity**

The cyclomatic complexity of the function.

Cyclomatic complexity is a software metric used to indicate the complexity of a program. It is a quantitative measure of the number of linearly independent paths through a program's source code. It is computed using the formula: M = E - N + 2P, where E = the number of edges in the graph, N = the number of nodes in the graph, P = the number of connected components.

The cyclomatic complexity value is lazily computed and cached for future use. Initially this value is None until it is computed for the first time

**Returns**
The cyclomatic complexity of the function.

**Return type**
int

**property block_addrs**

An iterator of all local block addresses in the current function.

**Returns**
block addresses.

**property block_addrs_set**

Return a set of block addresses for a better performance of inclusion tests.

**Returns**
A set of block addresses.

**Return type**
set

**get_block**(*addr*, *size=None*, *byte_string=None*)

Getting a block out of the current function.

**Parameters**

- **addr** (int) – The address of the block.
- **size** (int | None) – The size of the block. This is optional. If not provided, angr will load
- **byte_string** (bytes | None)

**Returns**

**get_block_size**(*addr*)

**Return type**
int | None

**Parameters**
**addr** (*int*)

**property nodes: Iterable[CodeNode]**

**get_node**(*addr*)

**Return type**
*BlockNode* | None

**property endpoints**

**property endpoints_with_type**

**property ret_sites**

**property jumpout_sites**

**property retout_sites**

**property callout_sites**

**property size**

**add_jumpout_site**(*node*)

Add a custom jumpout site.

**Parameters**
**node** (*CodeNode*) – The address of the basic block that control flow leaves during this transition.

**Returns**
None

**add_retout_site**(*node*)

Add a custom retout site.

**Parameters**
**node** (CodeNode)

**property transition_graph: DiGraph**

A read-only networkx view of the transition graph, created on-demand and kept in sync with the Function's updates.

**property startpoint: *CodeNode* | None**

**clear_transition_graph**()

**confirm_fakeret**(*src*, *dst*)

**transit_to**(*from_node*, *to_node*, *outside=False*, *ins_addr=None*, *stmt_idx=None*, *is_exception=False*, *update_func_block_count=True*)

Registers an edge between basic blocks in this function's transition graph.

:param from_node The address of the basic block that begins this transition. :param to_node The address of the basic block that ends this transition. :type outside: bool :param outside: If this is a transition to another function. :return: None

**Parameters**

- **from_node** (CodeNode)

- **update_func_block_count** (*bool*)

**call_to**(*from_node*, *to_func*, *ret_node*, *stmt_idx=None*, *ins_addr=None*, *return_to_outside=False*, *syscall=False*, *update_func_block_count=True*)

Registers an edge between the caller basic block and callee function.

**Parameters**

- **from_node** – The basic block that control flow leaves during the transition.
- **to_func** (*FuncNode* | *HookNode*) – The function that we are calling, represented as a FuncNode.
- **ret_node** – The basic block that control flow should return to after the function call.
- **stmt_idx** – Statement ID of this call.
- **ins_addr** – Instruction address of this call.
- **syscall** (*bool*)
- **update_func_block_count** (*bool*)

**fakeret_to**(*from_node*, *to_node*, *confirmed=None*, *to_outside=False*, *update_func_block_count=True*)

**Parameters**

**update_func_block_count** (*bool*)

**remove_fakeret**(*from_node*, *to_node*)

**return_from_call**(*from_func*, *to_node*, *to_outside=False*, *confirm_fakeret=True*)

**Parameters**

- **from_func** (FuncNode | HookNode)
- **confirm_fakeret** (*bool*)

**update_func_block_count**()

Update the cached block count of this function in the function manager.

**Return type**

None

**add_return_site**(*return_site*)

Registers a basic block as a site for control flow to return from this function.

**Parameters**

**return_site** (*CodeNode*) – The block node that ends with a return.

**add_call_site**(*call_site_addr*, *call_target_addr*, *retn_addr*)

Registers a basic block as calling a function and returning somewhere.

**Parameters**

- **call_site_addr** – The address of a basic block that ends in a call.
- **call_target_addr** – The address of the target of said call.
- **retn_addr** – The address that said call will return to.

**add_endpoint**(*endpoint_node*, *sort*)

Registers an endpoint with a type of *sort*. The type can be one of the following: - call: calling a function that does not return - return: returning from the current function - transition: a jump/branch targeting a different function

**Parameters**

- **endpoint_node** – The endpoint node.
- **sort** – Type of the endpoint.

**Returns**
None

`mark_nonreturning_calls_endpoints()`

Iterate through all call edges in transition graph. For each call a non-returning function, mark the source basic block as an endpoint.

This method should only be executed once all functions are recovered and analyzed by CFG recovery, so we know whether each function returns or not.

**Returns**
None

`property call_sites`

`get_call_sites()`

Gets a list of all the basic blocks that end in calls.

**Return type**
Iterable[int]

**Returns**
A view of the addresses of the blocks that end in calls.

`get_call_target(callsite_addr)`

Get the target of a call.

**Parameters**
**callsite_addr** – The address of a basic block that ends in a call.

**Returns**
The target of said call, or None if callsite_addr is not a callsite.

`get_call_return(callsite_addr)`

Get the hypothetical return address of a call.

**Parameters**
**callsite_addr** – The address of the basic block that ends in a call.

**Returns**
The likely return target of said call, or None if callsite_addr is not a callsite.

`property graph: networkx.DiGraph[CodeNode]`

Get a local transition graph. A local transition graph is a transition graph that only contains nodes that belong to the current function. All edges, except for the edges going out from the current function or coming from outside the current function, are included.

The generated graph is cached in self._local_transition_graph.

**Returns**
A local transition graph.

**Return type**
networkx.DiGraph

**subgraph**(*ins_addrs*)

Generate a sub control flow graph of instruction addresses based on self.graph

**Parameters**
**ins_addrs** (*iterable*) – A collection of instruction addresses that should be included in the subgraph.

**Return networkx.DiGraph**
A subgraph.

**dbg_print**()

Returns a representation of the list of basic blocks in this function.

**property has_return**

**copy**()

**remove_edge**(*from_node*, *to_node*)

**Return type**
None

### angr.knowledge_plugins.functions.transition_graph

**exception** angr.knowledge_plugins.functions.transition_graph.**ReadOnlyGraphError**

Bases: NetworkXError

Raised by every mutating operation on a Function graph view.

**class** angr.knowledge_plugins.functions.transition_graph.**ReadOnlyAttrDict**

Bases: dict

The attribute dictionary of a node, an edge or the graph of a Function graph view. every write raises ReadOnlyGraphError. Copies (copy(), dict(d), pickling, and copy.deepcopy) become plain dicts.

**clear**() → None. Remove all items from D.

**pop**(*k*[, *d* ]) → v, remove specified key and return the corresponding value.
If the key is not found, return the default if given; otherwise, raise a KeyError.

**popitem**(**_kwargs*)
Remove and return a (key, value) pair as a 2-tuple.

Pairs are returned in LIFO (last-in, first-out) order. Raises KeyError if the dict is empty.

**setdefault**(**_kwargs*)
Insert key with a value of default if key is not in the dictionary.

Return the value for key if key is in the dictionary, else default.

**update**([*E*, ]***F*) → None. Update D from mapping/iterable E and F.
If E is present and has a .keys() method, then does: for k in E.keys(): D[k] = E[k] If E is present and lacks a .keys() method, then does: for k, v in E: D[k] = v In either case, this is followed by: for k in F: D[k] = F[k]

**class** angr.knowledge_plugins.functions.transition_graph.**TransitionGraph**

Bases: DiGraph

A read-only DiGraph for the transition graph or local transition graph of a function. The owning Function keeps this DiGraph in sync with the actual store. All copying operations will convert this TransitionGraph into a plain networkx.DiGraph instance, in which case the original Function owner no longer keeps the copied instance in sync.

**frozen = True**

**node_attr_dict_factory**

alias of *ReadOnlyAttrDict*

**edge_attr_dict_factory**

alias of *ReadOnlyAttrDict*

**add_node**(***_kwargs*)

Add a single node *node_for_adding* and update node attributes.

**Parameters**

- **node_for_adding** (*node*) – A node can be any hashable Python object except None.
- **attr** (*keyword arguments, optional*) – Set or change node attributes using key=value.

**See also**

*add_nodes_from*

### Examples

```
>>> G = nx.Graph()  # or DiGraph, MultiGraph, MultiDiGraph, etc
>>> G.add_node(1)
>>> G.add_node("Hello")
>>> K3 = nx.Graph([(0, 1), (1, 2), (2, 0)])
>>> G.add_node(K3)
>>> G.number_of_nodes()
3
```

Use keywords set/change node attributes:

```
>>> G.add_node(1, size=10)
>>> G.add_node(3, weight=0.4, UTM=("13S", 382871, 3972649))
```

### Notes

A hashable object is one that can be used as a key in a Python dictionary. This includes strings, numbers, tuples of strings and numbers, etc.

On many platforms hashable items also include mutables such as NetworkX Graphs, though one should be careful that the hash doesn't change on mutables.

**add_nodes_from**(***_kwargs*)

Add multiple nodes.

**Parameters**

- **nodes_for_adding** (*iterable container*) – A container of nodes (list, dict, set, etc.). OR A container of (node, attribute dict) tuples. Node attributes are updated using the attribute dict.
- **attr** (*keyword arguments, optional (default= no attributes)*) – Update attributes for all nodes in nodes. Node attributes specified in nodes as a tuple take precedence over attributes specified via keyword arguments.

**See also**

*add_node*

### Notes

When adding nodes from an iterator over the graph you are changing, a *RuntimeError* can be raised with message: *RuntimeError: dictionary changed size during iteration*. This happens when the graph's underlying dictionary is modified during iteration. To avoid this error, evaluate the iterator into a separate object, e.g. by using *list(iterator_of_nodes)*, and pass this object to *G.add_nodes_from*.

### Examples

```
>>> G = nx.Graph()  # or DiGraph, MultiGraph, MultiDiGraph, etc
>>> G.add_nodes_from("Hello")
>>> K3 = nx.Graph([(0, 1), (1, 2), (2, 0)])
>>> G.add_nodes_from(K3)
>>> sorted(G.nodes(), key=str)
[0, 1, 2, 'H', 'e', 'l', 'o']
```

Use keywords to update specific node attributes for every node.

```
>>> G.add_nodes_from([1, 2], size=10)
>>> G.add_nodes_from([3, 4], weight=0.4)
```

Use (node, attrdict) tuples to update attributes for specific nodes.

```
>>> G.add_nodes_from([(1, dict(size=11)), (2, {"color": "blue"})])
>>> G.nodes[1]["size"]
11
>>> H = nx.Graph()
>>> H.add_nodes_from(G.nodes(data=True))
>>> H.nodes[1]["size"]
11
```

Evaluate an iterator over a graph if using it to modify the same graph

```
>>> G = nx.DiGraph([(0, 1), (1, 2), (3, 4)])
>>> # wrong way - will raise RuntimeError
>>> # G.add_nodes_from(n + 1 for n in G.nodes)
>>> # correct way
>>> G.add_nodes_from(list(n + 1 for n in G.nodes))
```

**add_edge**(***_kwargs*)

Add an edge between u and v.

The nodes u and v will be automatically added if they are not already in the graph.

Edge attributes can be specified with keywords or by directly accessing the edge's attribute dictionary. See examples below.

**Parameters**

- **u_of_edge** (nodes) – Nodes can be, for example, strings or numbers. Nodes must be hashable (and not None) Python objects.

- **v_of_edge** (nodes) – Nodes can be, for example, strings or numbers. Nodes must be hashable (and not None) Python objects.
- **attr** (*keyword arguments, optional*) – Edge data (or labels or objects) can be assigned using keyword arguments.

**See also**

*add_edges_from*
add a collection of edges

### Notes

Adding an edge that already exists updates the edge data.

Many NetworkX algorithms designed for weighted graphs use an edge attribute (by default *weight*) to hold a numerical value.

### Examples

The following all add the edge e=(1, 2) to graph G:

```
>>> G = nx.Graph()  # or DiGraph, MultiGraph, MultiDiGraph, etc
>>> e = (1, 2)
>>> G.add_edge(1, 2)  # explicit two-node form
>>> G.add_edge(*e)  # single edge as tuple of two nodes
>>> G.add_edges_from([(1, 2)])  # add edges from iterable container
```

Associate data to edges using keywords:

```
>>> G.add_edge(1, 2, weight=3)
>>> G.add_edge(1, 3, weight=7, capacity=15, length=342.7)
```

For non-string attribute keys, use subscript notation.

```
>>> G.add_edge(1, 2)
>>> G[1][2].update({0: 5})
>>> G.edges[1, 2].update({0: 5})
```

**add_edges_from**(**_kwargs*)

Add all the edges in ebunch_to_add.

**Parameters**

- **ebunch_to_add** (*container of* edges) – Each edge given in the container will be added to the graph. The edges must be given as 2-tuples (u, v) or 3-tuples (u, v, d) where d is a dictionary containing edge data.
- **attr** (*keyword arguments, optional*) – Edge data (or labels or objects) can be assigned using keyword arguments.

**See also**

*add_edge*
: add a single edge

*add_weighted_edges_from*
: convenient way to add weighted edges

### Notes

Adding the same edge twice has no effect but any edge data will be updated when each duplicate edge is added.

Edge attributes specified in an ebunch take precedence over attributes specified via keyword arguments.

When adding edges from an iterator over the graph you are changing, a *RuntimeError* can be raised with message: *RuntimeError: dictionary changed size during iteration*. This happens when the graph's underlying dictionary is modified during iteration. To avoid this error, evaluate the iterator into a separate object, e.g. by using *list(iterator_of_edges)*, and pass this object to *G.add_edges_from*.

### Examples

```
>>> G = nx.Graph()  # or DiGraph, MultiGraph, MultiDiGraph, etc
>>> G.add_edges_from([(0, 1), (1, 2)])  # using a list of edge tuples
>>> e = zip(range(0, 3), range(1, 4))
>>> G.add_edges_from(e)  # Add the path graph 0-1-2-3
```

Associate data to edges

```
>>> G.add_edges_from([(1, 2), (2, 3)], weight=3)
>>> G.add_edges_from([(3, 4), (1, 4)], label="WN2898")
```

Evaluate an iterator over a graph if using it to modify the same graph

```
>>> G = nx.DiGraph([(1, 2), (2, 3), (3, 4)])
>>> # Grow graph by one new node, adding edges to all existing nodes.
>>> # wrong way - will raise RuntimeError
>>> # G.add_edges_from(((5, n) for n in G.nodes))
>>> # right way - note that there will be no self-edge for node 5
>>> G.add_edges_from(list((5, n) for n in G.nodes))
```

**add_weighted_edges_from**(***_kwargs*)

Add weighted edges in *ebunch_to_add* with specified weight attr

**Parameters**

- **ebunch_to_add** (*container of* edges) – Each edge given in the list or container will be added to the graph. The edges must be given as 3-tuples (u, v, w) where w is a number.
- **weight** (string, optional *(default= 'weight')*) – The attribute name for the edge weights to be added.
- **attr** (*keyword arguments*, optional *(default= no attributes)*) – Edge attributes to add/update for all edges.

**See also**

*add_edge*
add a single edge

*add_edges_from*
add multiple edges

### Notes

Adding the same edge twice for Graph/DiGraph simply updates the edge data. For MultiGraph/MultiDiGraph, duplicate edges are stored.

When adding edges from an iterator over the graph you are changing, a *RuntimeError* can be raised with message: *RuntimeError: dictionary changed size during iteration*. This happens when the graph's underlying dictionary is modified during iteration. To avoid this error, evaluate the iterator into a separate object, e.g. by using *list(iterator_of_edges)*, and pass this object to *G.add_weighted_edges_from*.

### Examples

```
>>> G = nx.Graph()  # or DiGraph, MultiGraph, MultiDiGraph, etc
>>> G.add_weighted_edges_from([(0, 1, 3.0), (1, 2, 7.5)])
```

Evaluate an iterator over edges before passing it

```
>>> G = nx.Graph([(1, 2), (2, 3), (3, 4)])
>>> weight = 0.1
>>> # Grow graph by one new node, adding edges to all existing nodes.
>>> # wrong way - will raise RuntimeError
>>> # G.add_weighted_edges_from(((5, n, weight) for n in G.nodes))
>>> # correct way - note that there will be no self-edge for node 5
>>> G.add_weighted_edges_from(list((5, n, weight) for n in G.nodes))
```

**remove_node**(***_kwargs*)

Remove node n.

Removes the node n and all adjacent edges. Attempting to remove a nonexistent node will raise an exception.

**Parameters**
**n** (*node*) – A node in the graph

**Raises**
**NetworkXError** – If n is not in the graph.

**See also**

*remove_nodes_from*

### Examples

```
>>> G = nx.path_graph(3)  # or DiGraph, MultiGraph, MultiDiGraph, etc
>>> list(G.edges)
[(0, 1), (1, 2)]
>>> G.remove_node(1)
>>> list(G.edges)
[]
```

**remove_nodes_from**(***_kwargs*)

Remove multiple nodes.

**Parameters**

**nodes** (*iterable container*) – A container of nodes (list, dict, set, etc.). If a node in the container is not in the graph it is silently ignored.

**See also**

*remove_node*

### Notes

When removing nodes from an iterator over the graph you are changing, a *RuntimeError* will be raised with message: *RuntimeError: dictionary changed size during iteration*. This happens when the graph's underlying dictionary is modified during iteration. To avoid this error, evaluate the iterator into a separate object, e.g. by using *list(iterator_of_nodes)*, and pass this object to *G.remove_nodes_from*.

### Examples

```
>>> G = nx.path_graph(3)  # or DiGraph, MultiGraph, MultiDiGraph, etc
>>> e = list(G.nodes)
>>> e
[0, 1, 2]
>>> G.remove_nodes_from(e)
>>> list(G.nodes)
[]
```

Evaluate an iterator over a graph if using it to modify the same graph

```
>>> G = nx.DiGraph([(0, 1), (1, 2), (3, 4)])
>>> # this command will fail, as the graph's dict is modified during iteration
>>> # G.remove_nodes_from(n for n in G.nodes if n < 2)
>>> # this command will work, since the dictionary underlying graph is not␣
↪modified
>>> G.remove_nodes_from(list(n for n in G.nodes if n < 2))
```

**remove_edge**(***_kwargs*)

Remove the edge between u and v.

**Parameters**

- **u** (nodes) – Remove the edge between nodes u and v.
- **v** (nodes) – Remove the edge between nodes u and v.

**Raises**

**NetworkXError** – If there is not an edge between u and v.

**See also**

*remove_edges_from*
remove a collection of edges

### Examples

```
>>> G = nx.Graph()  # or DiGraph, etc
>>> nx.add_path(G, [0, 1, 2, 3])
>>> G.remove_edge(0, 1)
>>> e = (1, 2)
>>> G.remove_edge(*e)  # unpacks e from an edge tuple
>>> e = (2, 3, {"weight": 7})  # an edge with attribute data
>>> G.remove_edge(*e[:2])  # select first part of edge tuple
```

**remove_edges_from**(***_kwargs*)

Remove all edges specified in ebunch.

**Parameters**

**ebunch** (*list or container of edge tuples*) – Each edge given in the list or container will be removed from the graph. The edges can be:

- 2-tuples (u, v) edge between u and v.
- 3-tuples (u, v, k) where k is ignored.

**See also**

*remove_edge*
remove a single edge

### Notes

Will fail silently if an edge in ebunch is not in the graph.

### Examples

```
>>> G = nx.path_graph(4)  # or DiGraph, MultiGraph, MultiDiGraph, etc
>>> ebunch = [(1, 2), (2, 3)]
>>> G.remove_edges_from(ebunch)
```

**clear**(***_kwargs*)

Remove all nodes and edges from the graph.

This also removes the name, and all graph, node, and edge attributes.

### Examples

```
>>> G = nx.path_graph(4)  # or DiGraph, MultiGraph, MultiDiGraph, etc
>>> G.clear()
>>> list(G.nodes)
[]
>>> list(G.edges)
[]
```

**clear_edges**(***_kwargs*)

Remove all edges from the graph without altering nodes.

### Examples

```
>>> G = nx.path_graph(4)  # or DiGraph, MultiGraph, MultiDiGraph, etc
>>> G.clear_edges()
>>> list(G.nodes)
[0, 1, 2, 3]
>>> list(G.edges)
[]
```

**update**(***_kwargs*)

Update the graph using nodes/edges/graphs as input.

Like dict.update, this method takes a graph as input, adding the graph's nodes and edges to this graph. It can also take two inputs: edges and nodes. Finally it can take either edges or nodes. To specify only nodes the keyword *nodes* must be used.

The collections of edges and nodes are treated similarly to the add_edges_from/add_nodes_from methods. When iterated, they should yield 2-tuples (u, v) or 3-tuples (u, v, datadict).

**Parameters**

- **edges** (*Graph object, collection of* edges*, or None*) – The first parameter can be a graph or some edges. If it has attributes *nodes* and *edges*, then it is taken to be a Graph-like object and those attributes are used as collections of nodes and edges to be added to the graph. If the first parameter does not have those attributes, it is treated as a collection of edges and added to the graph. If the first argument is None, no edges are added.
- **nodes** (*collection of* nodes*, or None*) – The second parameter is treated as a collection of nodes to be added to the graph unless it is None. If *edges is None* and *nodes is None* an exception is raised. If the first parameter is a Graph, then *nodes* is ignored.

### Examples

```
>>> G = nx.path_graph(5)
>>> G.update(nx.complete_graph(range(4, 10)))
>>> from itertools import combinations
>>> edges = (
...     (u, v, {"power": u * v})
...     for u, v in combinations(range(10, 20), 2)
...     if u * v < 225
... )
>>> nodes = [1000]  # for singleton, use a container
>>> G.update(edges, nodes)
```

### Notes

It you want to update the graph using an adjacency structure it is straightforward to obtain the edges/nodes from adjacency. The following examples provide common cases, your adjacency may be slightly different and require tweaks of these examples:

```
>>> # dict-of-set/list/tuple
>>> adj = {1: {2, 3}, 2: {1, 3}, 3: {1, 2}}
>>> e = [(u, v) for u, nbrs in adj.items() for v in nbrs]
>>> G.update(edges=e, nodes=adj)
```

```
>>> DG = nx.DiGraph()
>>> # dict-of-dict-of-attribute
>>> adj = {1: {2: 1.3, 3: 0.7}, 2: {1: 1.4}, 3: {1: 0.7}}
>>> e = [
...     (u, v, {"weight": d})
...     for u, nbrs in adj.items()
...     for v, d in nbrs.items()
... ]
>>> DG.update(edges=e, nodes=adj)
```

```
>>> # dict-of-dict-of-dict
>>> adj = {1: {2: {"weight": 1.3}, 3: {"color": 0.7, "weight": 1.2}}}
>>> e = [
...     (u, v, {"weight": d})
...     for u, nbrs in adj.items()
...     for v, d in nbrs.items()
... ]
>>> DG.update(edges=e, nodes=adj)
```

```
>>> # predecessor adjacency (dict-of-set)
>>> pred = {1: {2, 3}, 2: {3}, 3: {3}}
>>> e = [(v, u) for u, nbrs in pred.items() for v in nbrs]
```

```
>>> # MultiGraph dict-of-dict-of-dict-of-attribute
>>> MDG = nx.MultiDiGraph()
>>> adj = {
...     1: {2: {0: {"weight": 1.3}, 1: {"weight": 1.2}}},
...     3: {2: {0: {"weight": 0.7}}},
... }
>>> e = [
...     (u, v, ekey, d)
...     for u, nbrs in adj.items()
...     for v, keydict in nbrs.items()
...     for ekey, d in keydict.items()
... ]
>>> MDG.update(edges=e)
```

### 10.24.9 angr.knowledge_plugins.indirect_jumps

**class** angr.knowledge_plugins.indirect_jumps.**IndirectJumps**

Bases: *KnowledgeBasePlugin*, dict

This plugin tracks the targets of indirect jumps

**update_resolved_addrs**(*indirect_address*, *resolved_addresses*)

**Parameters**

- **indirect_address** (*int*)
- **resolved_addresses** (*list[int]*)

### 10.24.10 angr.knowledge_plugins.key_definitions

**class** angr.knowledge_plugins.key_definitions.**Definition**

Bases: Generic[A, CodeLoc]

An atom definition.

**Variables**

- **atom** – The atom being defined.
- **codeloc** – Where this definition is created in the original binary code.
- **dummy** – Tell whether the definition should be considered dummy or not. During simplification by AILment, definitions marked as dummy will not be removed.
- **tags** – A set of tags containing information about the definition gathered during analyses.

**__init__**(*atom*, *codeloc*, *dummy=False*, *tags=None*)

**Parameters**

- **atom** (*A*)
- **codeloc** (*CodeLoc*)
- **dummy** (*bool*)
- **tags** (*set[Tag] | None*)

**atom**

**codeloc**

**dummy**

**tags**

**property offset:** int

**property size:** int

**matches**(***kwargs*)

Return whether this definition has certain characteristics.

**Return type**
bool

**class** angr.knowledge_plugins.key_definitions.**DerefSize**

Bases: Enum

An enum for specialized kinds of dereferences

**NULL_TERMINATE - Dereference until the first byte which could be a literal null. Return a value including the**
terminator.

NULL_TERMINATE = 1

class angr.knowledge_plugins.key_definitions.**KeyDefinitionManager**

Bases: *KnowledgeBasePlugin*

KeyDefinitionManager manages and caches reaching definition models for each function.

For each function, by default we cache the entire reaching definitions model with observed results at the following locations: - Before each call instruction: ('insn', address of the call instruction, OP_BEFORE) - After returning from each call: ('node', address of the block that ends with a call, OP_AFTER)

**__init__**(*kb*)

**Parameters**
**kb** (KnowledgeBase)

**has_model**(*func_addr*)

**Parameters**
**func_addr** (*int*)

**get_model**(*func_addr*)

**Parameters**
**func_addr** (*int*)

**copy**()

**Return type**
*KeyDefinitionManager*

class angr.knowledge_plugins.key_definitions.**LiveDefinitions**

Bases: object

A LiveDefinitions instance contains definitions and uses for register, stack, memory, and temporary variables, uncovered during the analysis.

INITIAL_SP_16BIT = 32512

INITIAL_SP_32BIT = 2147418112

INITIAL_SP_64BIT = 140737488289792

**__init__**(*arch*, *track_tmps=False*, *canonical_size=8*, *registers=None*, *stack=None*, *memory=None*, *heap=None*, *tmps=None*, *others=None*, *register_uses=None*, *stack_uses=None*, *heap_uses=None*, *memory_uses=None*, *tmp_uses=None*, *other_uses=None*, *element_limit=5*, *merge_into_tops=True*)

**Parameters**

- **arch** (*Arch*)
- **track_tmps** (*bool*)
- **merge_into_tops** (*bool*)

**project**: *Project* | None

**arch**

**track_tmps**

**registers:** *MultiValuedMemory*

**stack:** *MultiValuedMemory*

**memory:** *MultiValuedMemory*

**heap:** *MultiValuedMemory*

**tmps:** dict[int, set[*Definition*]]

**others:** dict[*Atom*, *MultiValues*]

**register_uses**

**stack_uses**

**heap_uses**

**memory_uses**

**tmp_uses:** dict[int, set[*CodeLocation*]]

**other_uses**

**uses_by_codeloc:** dict[*CodeLocation*, set[*Definition*]]

**copy**(*discard_tmpdefs=False*)

**Return type**
*LiveDefinitions*

**reset_uses**()

**static top**(*bits*)

Get a TOP value.

**Parameters**
**bits** (int) – Width of the TOP value (in bits).

**Returns**
The TOP value.

**static is_top**(*expr*)

Check if the given expression is a TOP value.

**Parameters**
**expr** – The given expression.

**Return type**
bool

**Returns**
True if the expression is TOP, False otherwise.

**stack_address**(*offset*)

**Return type**
BV

**Parameters**
**offset** (*int*)

static **is_stack_address**(*addr*)

**Return type**
bool

**Parameters**
**addr** (*Base*)

static **get_stack_offset**(*addr*, *had_stack_base=False*)

**Return type**
int | None

**Parameters**
**addr** (*Base*)

static **annotate_with_def**(*symvar*, *definition*)

**Parameters**

- **symvar** (BV)
- **definition** (*Definition*)

**Return type**
BV

**Returns**

static **extract_defs**(*symvar*)

**Return type**
Generator[*Definition*]

**Parameters**
**symvar** (*Base*)

static **extract_defs_from_annotations**(*annos*)

**Return type**
set[*Definition*]

**Parameters**
**annos** (*Iterable[Annotation]*)

static **extract_defs_from_mv**(*mv*)

**Return type**
Generator[*Definition*]

**Parameters**
**mv** (MultiValues)

**get_sp**()
Return the concrete value contained by the stack pointer.

**Return type**
int

**get_sp_offset**()
Return the offset of the stack pointer.

**Return type**
int | None

**get_stack_address**(*offset*)

**Return type**
int | None

**Parameters**
**offset** (*Base*)

**stack_offset_to_stack_addr**(*offset*)

**Return type**
int

**merge**(**others*)

**Return type**
tuple[*LiveDefinitions*, bool]

**Parameters**
**others** (LiveDefinitions)

**subsumes**(*other*)

**Return type**
bool

**Parameters**
**other** (LiveDefinitions)

**kill_definitions**(*atom*)

Overwrite existing definitions w.r.t 'atom' with a dummy definition instance. A dummy definition will not be removed during simplification.

**Parameters**
**atom** (*Atom*)

**Return type**
None

**Returns**
None

**kill_and_add_definition**(*atom*, *code_loc*, *data*, *dummy=False*, *tags=None*, *endness=None*, *annotated=False*)

**Return type**
*MultiValues* | None

**Parameters**

- **atom** (Atom)
- **code_loc** (CodeLocation)
- **data** (MultiValues)
- **tags** (*set[Tag] | None*)

**add_use**(*atom*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **atom** (Atom)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

**add_use_by_def**(*definition*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **definition** (Definition)
- **code_loc** (CodeLocation)
- **expr** (*Any*)

**get_definitions**(*thing*)

**Return type**
set[Definition[Atom]]

**Parameters**
**thing** (Atom | Definition[Atom] | Iterable[Atom] | Iterable[Definition[Atom]] | MultiValues)

**get_tmp_definitions**(*tmp_idx*)

**Return type**
set[*Definition*]

**Parameters**
**tmp_idx** (*int*)

**get_register_definitions**(*reg_offset*, *size*)

**Return type**
set[*Definition*]

**Parameters**

- **reg_offset** (*int*)
- **size** (*int*)

**get_stack_values**(*stack_offset*, *size*, *endness*)

**Return type**
*MultiValues* | None

**Parameters**

- **stack_offset** (*int*)
- **size** (*int*)
- **endness** (*str*)

**get_stack_definitions**(*stack_offset*, *size*)

**Return type**
set[*Definition*]

**Parameters**

- **stack_offset** (*int*)
- **size** (*int*)

**get_heap_definitions**(*heap_addr*, *size*)

**Return type**
set[*Definition*]

**Parameters**

- **heap_addr** (*int*)
- **size** (*int*)

**get_memory_definitions**(*addr*, *size*)

**Return type**
set[*Definition*]

**Parameters**

- **addr** (*int*)
- **size** (*int*)

**get_values**(*spec*, *endness=None*)

**Return type**
*MultiValues* | None

**Parameters**

- **spec** (*A | Definition[A] | Iterable[A] | Iterable[Definition[A]]*)
- **endness** (*archinfo.Endness | None*)

**get_one_value**(*spec*, *strip_annotations=False*)

**Return type**
BV | None

**Parameters**

- **spec** (*A | Definition[A] | Iterable[A] | Iterable[Definition[A]]*)
- **strip_annotations** (*bool*)

**get_concrete_value**(*spec*, *cast_to=<class 'int'>*)

**Overloads**

- **spec** (A | Definition[A] | Iterable[A] | Iterable[Definition[A]]), **cast_to** (type[int]) → int | None
- **spec** (A | Definition[A] | Iterable[A] | Iterable[Definition[A]]), **cast_to** (type[bytes]) → bytes | None

**Parameters**

- **spec** (*A | Definition[A] | Iterable[A] | Iterable[Definition[A]]*)
- **cast_to** (type[*int | bytes*])

**Return type**
int | *bytes* | None

add_register_use(*reg_offset*, *size*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **reg_offset** (*int*)
- **size** (*int*)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

add_register_use_by_def(*def_*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **def_** (Definition)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

add_stack_use(*atom*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **atom** (MemoryLocation)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

add_stack_use_by_def(*def_*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **def_** (Definition)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

add_heap_use(*atom*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **atom** (MemoryLocation)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

**add_heap_use_by_def**(*def_*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **def_** (Definition)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

**add_memory_use**(*atom*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **atom** (MemoryLocation)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

**add_memory_use_by_def**(*def_*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **def_** (Definition)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

**add_tmp_use**(*atom*, *code_loc*)

**Return type**
None

**Parameters**

- **atom** (Tmp)
- **code_loc** (CodeLocation)

**add_tmp_use_by_def**(*def_*, *code_loc*)

**Return type**
None

**Parameters**

- **def_** (Definition)
- **code_loc** (CodeLocation)

**deref**(*pointer*, *size*, *endness=Endness.BE*)

**Overloads**

- **pointer** (MultiValues | Atom | Definition[Atom] | Iterable[Atom] | Iterable[Definition[Atom]]), **size** (int | *DerefSize*), **endness** (Endness) = ... → set[*MemoryLocation*]

- **pointer** (int | BV | *HeapAddress* | *SpOffset*), **size** (int | *DerefSize*), **endness** (Endness) = ... → *MemoryLocation* | None

**static is_heap_address**(*addr*)

**Return type**
bool

**Parameters**
**addr** (*Base*)

**static get_heap_offset**(*addr*)

**Return type**
int | None

**Parameters**
**addr** (*Base*)

**heap_address**(*offset*)

**Return type**
BV

**Parameters**
**offset** (*int* | HeapAddress)

**class** angr.knowledge_plugins.key_definitions.**ReachingDefinitionsModel**

Bases: object

Models the definitions, uses, and memory of a ReachingDefinitionState object

**__init__**(*func_addr=None*, *track_liveness=True*)

**Parameters**

- **func_addr** (*int* | *None*)
- **track_liveness** (*bool*)

**add_def**(*d*)

**Return type**
None

**Parameters**
**d** (Definition)

**kill_def**(*d*)

**Return type**
None

**Parameters**
**d** (Definition)

**at_new_stmt**(*codeloc*)

**Return type**
None

**Parameters**
**codeloc** (CodeLocation)

**at_new_block**(*code_loc*, *pred_codelocs*)

**Return type**
None

**Parameters**

- **code_loc** (CodeLocation)
- **pred_codelocs** (*list*[CodeLocation])

**make_liveness_snapshot**()

**Return type**
None

**find_defs_at**(*code_loc*, *op=ObservationPointType.OP_BEFORE*)

**Return type**
set[*Definition*]

**Parameters**

- **code_loc** (CodeLocation)
- **op** (*int*)

**get_defs**(*atom*, *code_loc*, *op*)

**Return type**
set[*Definition*]

**Parameters**

- **atom** (Atom)
- **code_loc** (CodeLocation)
- **op** (*int*)

**copy**()

**Return type**
*ReachingDefinitionsModel*

**merge**(*model*)

**Parameters**
**model** (ReachingDefinitionsModel)

**get_observation_by_insn**(*ins_addr*, *kind*)

**Return type**
*LiveDefinitions* | None

**Parameters**

- **ins_addr** (*int* | CodeLocation)
- **kind** (ObservationPointType)

**get_observation_by_node**(*node_addr*, *kind*, *node_idx=None*)

**Return type**
*LiveDefinitions* | None

**Parameters**

- **node_addr** (*int* | CodeLocation)
- **kind** (ObservationPointType)
- **node_idx** (*int* | *None*)

**get_observation_by_stmt**(*arg1*, *arg2*, *arg3=None*, ***, *block_idx=None*)

**Overloads**

- **codeloc** (*CodeLocation*), **kind** () → *LiveDefinitions* | None
- **node_addr** (int), **stmt_idx** (int), **kind** (), ***, **block_idx** (int | None) = None

**get_observation_by_exit**(*node_addr*, *stmt_idx*, *src_node_idx=None*)

**Return type**
*LiveDefinitions* | None

**Parameters**

- **node_addr** (*int*)
- **stmt_idx** (*int*)
- **src_node_idx** (*int* | *None*)

**class** angr.knowledge_plugins.key_definitions.**Uses**

Bases: object

Describes uses (including the use location and the use expression) for definitions.

**__init__**(*uses_by_definition=None*, *uses_by_location=None*)

**Parameters**

- **uses_by_definition** (DefaultChainMapCOW | *None*)
- **uses_by_location** (DefaultChainMapCOW | *None*)

**add_use**(*definition*, *codeloc*, *expr=None*)

Add a use for a given definition.

**Parameters**

- **definition** (*Definition*) – The definition that is used.
- **codeloc** (*CodeLocation*) – The code location where the use occurs.
- **expr** (Any | None) – The expression that uses the specified definition at this location.

**get_uses**(*definition*)

Retrieve the uses of a given definition.

**Parameters**
**definition** (*Definition*) – The definition for which we get the uses.

**Return type**
set[*CodeLocation*]

**get_uses_with_expr**(*definition*)

Retrieve the uses and the corresponding expressions of a given definition.

**Parameters**
**definition** (*Definition*) – The definition for which we get the uses and the corresponding expressions.

**Return type**
set[tuple[*CodeLocation*, Any | None]]

**remove_use**(*definition*, *codeloc*, *expr=None*)

Remove one use of a given definition.

**Parameters**

- **definition** (*Definition*) – The definition of which to remove the uses.
- **codeloc** (*CodeLocation*) – The code location where the use is.
- **expr** (Any | None) – The expression that uses the definition at the given location.

**Return type**
None

**Returns**
None

**remove_uses**(*definition*)

Remove all uses of a given definition.

**Parameters**
**definition** (*Definition*) – The definition of which to remove the uses.

**Returns**
None

**get_uses_by_location**(*codeloc*, *exprs=False*)

Retrieve all definitions that are used at a given location.

**Parameters**

- **codeloc** (*CodeLocation*) – The code location.
- **exprs** (*bool*)

**Return type**
set[*Definition*] | set[tuple[*Definition*, Any | None]]

**Returns**
A set of definitions that are used at the given location.

**get_uses_by_insaddr**(*ins_addr*, *exprs=False*)

Retrieve all definitions that are used at a given location specified by the instruction address.

**Parameters**

- **ins_addr** (int) – The instruction address.
- **exprs** (*bool*)

**Return type**
set[*Definition*] | set[tuple[*Definition*, Any | None]]

**Returns**
A set of definitions that are used at the given location.

**copy**()

Copy the instance.

**Return type**
*Uses*

**Returns**
Return a new <Uses> instance containing the same data.

**merge**(*other*)

Merge an instance of <Uses> into the current instance.

**Parameters**
**other** (*Uses*) – The other <Uses> from which the data will be added to the current instance.

**Return type**
bool

**Returns**
True if any merge occurred, False otherwise

### angr.knowledge_plugins.key_definitions.atoms

**class** angr.knowledge_plugins.key_definitions.atoms.**AtomKind**

Bases: Enum

An enum indicating the class of an atom

**REGISTER = 1**

**MEMORY = 2**

**TMP = 3**

**GUARD = 4**

**CONSTANT = 5**

**class** angr.knowledge_plugins.key_definitions.atoms.**Atom**

Bases: object

This class represents a data storage location manipulated by IR instructions.

It could either be a Tmp (temporary variable), a Register, a MemoryLocation.

**__init__**(*size*)

**Parameters**
**size** – The size of the atom in bytes

**size**

**property bits: int**

**static from_ail_expr**(*expr*, *arch*, *full_reg=False*)

**Return type**
*Register*

**Parameters**

- **expr** (Expression)
- **arch** (*Arch*)
- **full_reg** (*bool*)

**static from_argument**(*argument*, *arch*, *full_reg=False*, *sp=None*)

Instantiate an *Atom* from a given argument.

**Parameters**

- **argument** (*SimFunctionArgument*) – The argument to create a new atom from.
- **arch** (Arch) – The argument representing archinfo architecture for argument.
- **full_reg** – Whether to return an atom indicating the entire register if the argument only specifies a slice of the register.
- **sp** (int | None) – The current stack offset. Optional. Only used when argument is a SimStackArg.

**Return type**
*Register* | *MemoryLocation*

**static reg**(*thing*, *size=None*, *arch=None*)

Create a Register atom.

**Parameters**

- **thing** (str | RegisterOffset) – The register offset (e.g., project.arch.registers["rax"][0]) or the register name (e.g., "rax").
- **size** (int | None) – Size of the register atom. Must be provided when creating the atom using a register offset.
- **arch** (Arch | None) – The architecture. Must be provided when creating the atom using a register name.

**Return type**
*Register*

**Returns**
The Register Atom object.

**static register**(*thing*, *size=None*, *arch=None*)

Create a Register atom.

**Parameters**

- **thing** (str | RegisterOffset) – The register offset (e.g., project.arch.registers["rax"][0]) or the register name (e.g., "rax").

- **size** (int | None) – Size of the register atom. Must be provided when creating the atom using a register offset.
- **arch** (Arch | None) – The architecture. Must be provided when creating the atom using a register name.

**Return type**
*Register*

**Returns**
The Register Atom object.

**static mem**(*addr*, *size*, *endness=None*)

Create a MemoryLocation atom,

**Parameters**

- **addr** (*SpOffset* | *HeapAddress* | int) – The memory location. Can be an SpOffset for stack variables, an int for global memory variables, or a HeapAddress for items on the heap.
- **size** (int) – Size of the atom.
- **endness** (Endness | None) – Optional, either "Iend_LE" or "Iend_BE".

**Return type**
*MemoryLocation*

**Returns**
The MemoryLocation Atom object.

**static memory**(*addr*, *size*, *endness=None*)

Create a MemoryLocation atom,

**Parameters**

- **addr** (*SpOffset* | *HeapAddress* | int) – The memory location. Can be an SpOffset for stack variables, an int for global memory variables, or a HeapAddress for items on the heap.
- **size** (int) – Size of the atom.
- **endness** (Endness | None) – Optional, either "Iend_LE" or "Iend_BE".

**Return type**
*MemoryLocation*

**Returns**
The MemoryLocation Atom object.

**class** angr.knowledge_plugins.key_definitions.atoms.**GuardUse**

Bases: *Atom*

Implements a guard use.

**target**

**class** angr.knowledge_plugins.key_definitions.atoms.**ConstantSrc**

Bases: *Atom*

Represents a constant.

**value:** int

class angr.knowledge_plugins.key_definitions.atoms.**Tmp**

Bases: *Atom*

Represents a variable used by the IR to store intermediate values.

**tmp_idx**

class angr.knowledge_plugins.key_definitions.atoms.**Register**

Bases: *Atom*

Represents a given CPU register.

As an IR abstracts the CPU design to target different architectures, registers are represented as a separated memory space. Thus a register is defined by its offset from the base of this memory and its size.

**Variables**

- **reg_offset** (*int*) – The offset from the base to define its place in the memory bloc.
- **size** (*int*) – The size, in number of bytes.

**reg_offset**

**name**(*arch*)

**Return type**
str

**Parameters**
**arch** (*Arch*)

class angr.knowledge_plugins.key_definitions.atoms.**VirtualVariable**

Bases: *Atom*

Represents a virtual variable.

**varid**

**category**

**oident**

**property was_reg:** bool

**property was_stack:** bool

**property was_parameter:** bool

**property was_tmp:** bool

**property reg_offset:** int | None

**property stack_offset:** int | None

**property tmp_idx:** int | None

class angr.knowledge_plugins.key_definitions.atoms.**MemoryLocation**

Bases: *Atom*

Represents a memory slice.

It is characterized by its address and its size.

__init__(*addr*, *size*, *endness=None*)

**Parameters**

- **addr** (*SpOffset* | *HeapAddress* | int) – The address of the beginning memory location slice.
- **size** (int) – The size of the represented memory location, in bytes.
- **endness** (*Endness* | *None*)

**addr:** *SpOffset* | int | BV

**endness**

**property is_on_stack:** bool

True if this memory location is located on the stack.

**property symbolic:** bool

### angr.knowledge_plugins.key_definitions.constants

**class** angr.knowledge_plugins.key_definitions.constants.**ObservationPointType**

Bases: IntEnum

Enum to replace the previously generic constants This makes it possible to annotate where they are expected by typing something as ObservationPointType instead of Literal[0,1]

**OP_BEFORE = 0**

**OP_AFTER = 1**

__new__(*value*)

### angr.knowledge_plugins.key_definitions.definition

**class** angr.knowledge_plugins.key_definitions.definition.**DefinitionMatchPredicate**

Bases: object

A dataclass indicating several facts which much all must match in order for a definition to match. Largely an internal class; don't worry about this.

**kind:** *AtomKind* | type[*Atom*] | None = None

**bbl_addr:** int | None = None

**ins_addr:** int | None = None

**variable:** *SimVariable* | None = None

**variable_manager:** Union[*VariableManagerInternal*, Literal[False], None] = None

**stack_offset:** int | None = None

**reg_name:** str | int | None = None

**heap_offset:** int | None = None

**global_addr:** int | None = None

**tmp_idx:** int | None = None

**const_val:** *int | None = None*

**extern:** *bool | None = None*

**arch:** *Arch | None = None*

**static construct**(*predicate=None*, ***kwargs*)

**Return type**
*DefinitionMatchPredicate*

**Parameters**
**predicate** (*DefinitionMatchPredicate | None*)

**normalize**()

**matches**(*defn*)

**Return type**
bool

**Parameters**
**defn** (*Definition*)

**__init__**(*kind=None*, *bbl_addr=None*, *ins_addr=None*, *variable=None*, *variable_manager=None*, *stack_offset=None*, *reg_name=None*, *heap_offset=None*, *global_addr=None*, *tmp_idx=None*, *const_val=None*, *extern=None*, *arch=None*)

**Parameters**

- **kind** (*AtomKind | type[Atom] | None*)
- **bbl_addr** (*int | None*)
- **ins_addr** (*int | None*)
- **variable** (*SimVariable | None*)
- **variable_manager** (*VariableManagerInternal | Literal[False] | None*)
- **stack_offset** (*int | None*)
- **reg_name** (*str | int | None*)
- **heap_offset** (*int | None*)
- **global_addr** (*int | None*)
- **tmp_idx** (*int | None*)
- **const_val** (*int | None*)
- **extern** (*bool | None*)
- **arch** (*Arch | None*)

**Return type**
None

**class** angr.knowledge_plugins.key_definitions.definition.**Definition**

Bases: Generic[A, CodeLoc]

An atom definition.

**Variables**

- **atom** – The atom being defined.
- **codeloc** – Where this definition is created in the original binary code.
- **dummy** – Tell whether the definition should be considered dummy or not. During simplification by AILment, definitions marked as dummy will not be removed.
- **tags** – A set of tags containing information about the definition gathered during analyses.

**__init__**(*atom*, *codeloc*, *dummy=False*, *tags=None*)

**Parameters**

- **atom** (*A*)
- **codeloc** (*CodeLoc*)
- **dummy** (*bool*)
- **tags** (*set[Tag] | None*)

**atom**

**codeloc**

**dummy**

**tags**

**property offset: int**

**property size: int**

**matches**(***kwargs*)

Return whether this definition has certain characteristics.

**Return type**
bool

### angr.knowledge_plugins.key_definitions.environment

**class** angr.knowledge_plugins.key_definitions.environment.**Environment**

Bases: object

Represent the environment in which a program runs. It's a mapping of variable names, to *claripy.ast.Base* that should contain possible addresses, or <UNDEFINED>, at which their respective values are stored.

**Note**: The <Environment> object does not store the values associated with variables themselves.

**__init__**(*environment=None*)

**Parameters**
**environment** (*dict[str | Undefined, set[Base]] | None*)

**get**(*names*)

**Parameters**
**names** (*set*[str]) – Potential values for the name of the environment variable to get the pointers of.

**Return type**
tuple[*set*[Base], bool]

**Returns**
The potential addresses of the values the environment variable can take; And a boolean value telling whether all the names were known of the internal representation (i.e. will be False if one of the queried variable was not found).

**set**(*name*, *pointers*)

**Parameters**

- **name** (str | *Undefined*) – Name of the environment variable to which we will associate the pointers.
- **pointers** (*set*[Base]) – New addresses where the new values of the environment variable are located.

**merge**(**others*)

**Return type**
tuple[*Environment*, bool]

**Parameters**
**others** (Environment)

**subsumes**(*other*)

**Return type**
bool

**Parameters**
**other** (Environment)

### angr.knowledge_plugins.key_definitions.heap_address

**class** angr.knowledge_plugins.key_definitions.heap_address.**HeapAddress**

Bases: object

The representation of an address on the heap.

**__init__**(*value*)

**Parameters**
**value** (*int* | Undefined)

**property value**

### angr.knowledge_plugins.key_definitions.key_definition_manager

**class** angr.knowledge_plugins.key_definitions.key_definition_manager.**RDAObserverControl**

Bases: object

**__init__**(*func_addr*, *call_site_block_addrs*, *call_site_ins_addrs*)

**Parameters**

- **func_addr** (*int*)
- **call_site_block_addrs** (*Iterable[int]*)
- **call_site_ins_addrs** (*Iterable[int]*)

**rda_observe_callback**(*ob_type*, ***kwargs*)

class angr.knowledge_plugins.key_definitions.key_definition_manager.**KeyDefinitionManager**

Bases: *KnowledgeBasePlugin*

KeyDefinitionManager manages and caches reaching definition models for each function.

For each function, by default we cache the entire reaching definitions model with observed results at the following locations: - Before each call instruction: ('insn', address of the call instruction, OP_BEFORE) - After returning from each call: ('node', address of the block that ends with a call, OP_AFTER)

**__init__**(*kb*)

**Parameters**
**kb** (KnowledgeBase)

**has_model**(*func_addr*)

**Parameters**
**func_addr** (*int*)

**get_model**(*func_addr*)

**Parameters**
**func_addr** (*int*)

**copy**()

**Return type**
*KeyDefinitionManager*

### angr.knowledge_plugins.key_definitions.live_definitions

class angr.knowledge_plugins.key_definitions.live_definitions.**DerefSize**

Bases: Enum

An enum for specialized kinds of dereferences

**NULL_TERMINATE - Dereference until the first byte which could be a literal null. Return a value including the**
terminator.

**NULL_TERMINATE = 1**

class angr.knowledge_plugins.key_definitions.live_definitions.**DefinitionAnnotation**

Bases: Annotation

An annotation that attaches a *Definition* to an AST.

**relocatable = True**

**eliminatable = False**

**__init__**(*definition*)

**definition**

class angr.knowledge_plugins.key_definitions.live_definitions.**LiveDefinitions**

Bases: object

A LiveDefinitions instance contains definitions and uses for register, stack, memory, and temporary variables, uncovered during the analysis.

INITIAL_SP_16BIT = 32512

INITIAL_SP_32BIT = 2147418112

INITIAL_SP_64BIT = 140737488289792

__init__(*arch*, *track_tmps=False*, *canonical_size=8*, *registers=None*, *stack=None*, *memory=None*, *heap=None*, *tmps=None*, *others=None*, *register_uses=None*, *stack_uses=None*, *heap_uses=None*, *memory_uses=None*, *tmp_uses=None*, *other_uses=None*, *element_limit=5*, *merge_into_tops=True*)

**Parameters**

- **arch** (*Arch*)
- **track_tmps** (*bool*)
- **merge_into_tops** (*bool*)

project: *Project* | None

arch

track_tmps

registers: *MultiValuedMemory*

stack: *MultiValuedMemory*

memory: *MultiValuedMemory*

heap: *MultiValuedMemory*

tmps: dict[int, set[*Definition*]]

others: dict[*Atom*, *MultiValues*]

register_uses

stack_uses

heap_uses

memory_uses

tmp_uses: dict[int, set[*CodeLocation*]]

other_uses

uses_by_codeloc: dict[*CodeLocation*, set[*Definition*]]

copy(*discard_tmpdefs=False*)

**Return type**
*LiveDefinitions*

reset_uses()

static top(*bits*)

Get a TOP value.

**Parameters**
**bits** (int) – Width of the TOP value (in bits).

**Returns**
The TOP value.

static is_top(*expr*)

Check if the given expression is a TOP value.

**Parameters**
**expr** – The given expression.

**Return type**
bool

**Returns**
True if the expression is TOP, False otherwise.

stack_address(*offset*)

**Return type**
BV

**Parameters**
**offset** (*int*)

static is_stack_address(*addr*)

**Return type**
bool

**Parameters**
**addr** (*Base*)

static get_stack_offset(*addr*, *had_stack_base=False*)

**Return type**
int | None

**Parameters**
**addr** (*Base*)

static annotate_with_def(*symvar*, *definition*)

**Parameters**

- **symvar** (BV)
- **definition** (*Definition*)

**Return type**
BV

**Returns**

static extract_defs(*symvar*)

**Return type**
Generator[*Definition*]

**Parameters**
**symvar** (*Base*)

**static extract_defs_from_annotations**(*annos*)

**Return type**
set[*Definition*]

**Parameters**
**annos** (*Iterable[Annotation]*)

**static extract_defs_from_mv**(*mv*)

**Return type**
Generator[*Definition*]

**Parameters**
**mv** (MultiValues)

**get_sp**()

Return the concrete value contained by the stack pointer.

**Return type**
int

**get_sp_offset**()

Return the offset of the stack pointer.

**Return type**
int | None

**get_stack_address**(*offset*)

**Return type**
int | None

**Parameters**
**offset** (*Base*)

**stack_offset_to_stack_addr**(*offset*)

**Return type**
int

**merge**(**others*)

**Return type**
tuple[*LiveDefinitions*, bool]

**Parameters**
**others** (LiveDefinitions)

**subsumes**(*other*)

**Return type**
bool

**Parameters**
**other** (LiveDefinitions)

**kill_definitions**(*atom*)

Overwrite existing definitions w.r.t 'atom' with a dummy definition instance. A dummy definition will not be removed during simplification.

**Parameters**
**atom** (*Atom*)

**Return type**
None

**Returns**
None

**kill_and_add_definition**(*atom*, *code_loc*, *data*, *dummy=False*, *tags=None*, *endness=None*, *annotated=False*)

**Return type**
*MultiValues* | None

**Parameters**

- **atom** (Atom)
- **code_loc** (CodeLocation)
- **data** (MultiValues)
- **tags** (*set[Tag] | None*)

**add_use**(*atom*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **atom** (Atom)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

**add_use_by_def**(*definition*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **definition** (Definition)
- **code_loc** (CodeLocation)
- **expr** (*Any*)

**get_definitions**(*thing*)

**Return type**
set[Definition[Atom]]

**Parameters**
**thing** (*Atom | Definition[Atom] | Iterable[Atom] | Iterable[Definition[Atom]] | MultiValues*)

get_tmp_definitions(*tmp_idx*)

**Return type**
set[*Definition*]

**Parameters**
**tmp_idx** (*int*)

get_register_definitions(*reg_offset*, *size*)

**Return type**
set[*Definition*]

**Parameters**

- **reg_offset** (*int*)
- **size** (*int*)

get_stack_values(*stack_offset*, *size*, *endness*)

**Return type**
*MultiValues* | None

**Parameters**

- **stack_offset** (*int*)
- **size** (*int*)
- **endness** (*str*)

get_stack_definitions(*stack_offset*, *size*)

**Return type**
set[*Definition*]

**Parameters**

- **stack_offset** (*int*)
- **size** (*int*)

get_heap_definitions(*heap_addr*, *size*)

**Return type**
set[*Definition*]

**Parameters**

- **heap_addr** (*int*)
- **size** (*int*)

get_memory_definitions(*addr*, *size*)

**Return type**
set[*Definition*]

**Parameters**

- **addr** (*int*)
- **size** (*int*)

`get_values`(*spec*, *endness=None*)

**Return type**
*MultiValues* | None

**Parameters**

- **spec** (*A | Definition[A] | Iterable[A] | Iterable[Definition[A]]*)
- **endness** (*archinfo.Endness | None*)

`get_one_value`(*spec*, *strip_annotations=False*)

**Return type**
BV | None

**Parameters**

- **spec** (*A | Definition[A] | Iterable[A] | Iterable[Definition[A]]*)
- **strip_annotations** (*bool*)

`get_concrete_value`(*spec*, *cast_to=<class 'int'>*)

**Overloads**

- **spec** (A | Definition[A] | Iterable[A] | Iterable[Definition[A]]), **cast_to** (type[int]) → int | None
- **spec** (A | Definition[A] | Iterable[A] | Iterable[Definition[A]]), **cast_to** (type[bytes]) → bytes | None

**Parameters**

- **spec** (*A | Definition[A] | Iterable[A] | Iterable[Definition[A]]*)
- **cast_to** (*type[int | bytes]*)

**Return type**
int | *bytes* | None

`add_register_use`(*reg_offset*, *size*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **reg_offset** (*int*)
- **size** (*int*)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

`add_register_use_by_def`(*def_*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **def_** (Definition)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

**add_stack_use**(*atom*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **atom** (MemoryLocation)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

**add_stack_use_by_def**(*def_*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **def_** (Definition)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

**add_heap_use**(*atom*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **atom** (MemoryLocation)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

**add_heap_use_by_def**(*def_*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **def_** (Definition)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

**add_memory_use**(*atom*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **atom** (MemoryLocation)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

**add_memory_use_by_def**(*def_*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **def_** (Definition)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

**add_tmp_use**(*atom*, *code_loc*)

**Return type**
None

**Parameters**

- **atom** (Tmp)
- **code_loc** (CodeLocation)

**add_tmp_use_by_def**(*def_*, *code_loc*)

**Return type**
None

**Parameters**

- **def_** (Definition)
- **code_loc** (CodeLocation)

**deref**(*pointer*, *size*, *endness=Endness.BE*)

**Overloads**

- **pointer** (MultiValues | Atom | Definition[Atom] | Iterable[Atom] | Iterable[Definition[Atom]]), **size** (int | *DerefSize*), **endness** (Endness) = ... → set[*MemoryLocation*]
- **pointer** (int | BV | *HeapAddress* | *SpOffset*), **size** (int | *DerefSize*), **endness** (Endness) = ... → *MemoryLocation* | None

**static is_heap_address**(*addr*)

**Return type**
bool

**Parameters**
**addr** (*Base*)

**static get_heap_offset**(*addr*)

**Return type**
int | None

**Parameters**
**addr** (*Base*)

**heap_address**(*offset*)

**Return type**
BV

**Parameters**
**offset** (*int* | HeapAddress)

### angr.knowledge_plugins.key_definitions.liveness

**class** angr.knowledge_plugins.key_definitions.liveness.**Liveness**

Bases: object

This class stores liveness information for each definition.

**__init__**()

**add_def**(*d*)

**Return type**
None

**Parameters**
**d** (Definition)

**kill_def**(*d*)

**Return type**
None

**Parameters**
**d** (Definition)

**make_liveness_snapshot**()

**Return type**
None

**at_new_stmt**(*code_loc*)

Only support moving from a statement to the next statement within one basic block.

**Return type**
None

**Parameters**
**code_loc** (CodeLocation)

**at_new_block**(*code_loc*, *pred_codelocs*)

Only support moving to a new block from one or more blocks.

**Return type**
None

**Parameters**

- **code_loc** (CodeLocation)
- **pred_codelocs** (*list*[CodeLocation])

**find_defs_at**(*code_loc*, *op=ObservationPointType.OP_BEFORE*)

**Return type**
set[*Definition*]

**Parameters**

- **code_loc** (CodeLocation)
- **op** (*int*)

**find_defs_at_raw**(*block_addr*, *block_idx*, *stmt_idx*, *op=ObservationPointType.OP_BEFORE*)

**Return type**
set[*Definition*]

**Parameters**

- **block_addr** (*int*)
- **block_idx** (*int | None*)
- **stmt_idx** (*int | None*)
- **op** (*int*)

**copy**()

**Return type**
*Liveness*

### angr.knowledge_plugins.key_definitions.rd_model

**class** angr.knowledge_plugins.key_definitions.rd_model.**ReachingDefinitionsModel**

Bases: object

Models the definitions, uses, and memory of a ReachingDefinitionState object

**__init__**(*func_addr=None*, *track_liveness=True*)

**Parameters**

- **func_addr** (*int | None*)
- **track_liveness** (*bool*)

**add_def**(*d*)

**Return type**
None

**Parameters**
**d** (Definition)

**kill_def**(*d*)

**Return type**
None

**Parameters**
**d** (Definition)

**at_new_stmt**(*codeloc*)

**Return type**
None

**Parameters**
**codeloc** (CodeLocation)

**at_new_block**(*code_loc*, *pred_codelocs*)

**Return type**
None

**Parameters**

- **code_loc** (CodeLocation)
- **pred_codelocs** (*list*[CodeLocation])

**make_liveness_snapshot**()

**Return type**
None

**find_defs_at**(*code_loc*, *op=ObservationPointType.OP_BEFORE*)

**Return type**
set[*Definition*]

**Parameters**

- **code_loc** (CodeLocation)
- **op** (*int*)

**get_defs**(*atom*, *code_loc*, *op*)

**Return type**
set[*Definition*]

**Parameters**

- **atom** (Atom)
- **code_loc** (CodeLocation)
- **op** (*int*)

**copy**()

**Return type**
*ReachingDefinitionsModel*

**merge**(*model*)

**Parameters**
**model** (ReachingDefinitionsModel)

**get_observation_by_insn**(*ins_addr*, *kind*)

**Return type**
*LiveDefinitions* | None

**Parameters**

- **ins_addr** (*int* | CodeLocation)
- **kind** (ObservationPointType)

**get_observation_by_node**(*node_addr*, *kind*, *node_idx=None*)

**Return type**
*LiveDefinitions* | None

**Parameters**

- **node_addr** (*int | CodeLocation*)
- **kind** (*ObservationPointType*)
- **node_idx** (*int | None*)

**get_observation_by_stmt**(*arg1*, *arg2*, *arg3=None*, ***, *block_idx=None*)

**Overloads**

- **codeloc** (*CodeLocation*), **kind** () → *LiveDefinitions* | None
- **node_addr** (int), **stmt_idx** (int), **kind** (), ***, **block_idx** (int | None) = None

**get_observation_by_exit**(*node_addr*, *stmt_idx*, *src_node_idx=None*)

**Return type**
*LiveDefinitions* | None

**Parameters**

- **node_addr** (*int*)
- **stmt_idx** (*int*)
- **src_node_idx** (*int | None*)

### angr.knowledge_plugins.key_definitions.tag

Classes to structure the different types of <Tag>s that can be attached to <Definition>s.

- **Tag**
  - **FunctionTag**
    - ParameterTag
    - LocalVariableTag
    - ReturnValueTag
  - InitialValueTag

**class** angr.knowledge_plugins.key_definitions.tag.**Tag**

Bases: object

A tag for a Definition that can carry different kinds of metadata.

**__init__**(*metadata=None*)

**Parameters**
**metadata** (*object*)

**class** angr.knowledge_plugins.key_definitions.tag.**FunctionTag**

Bases: *Tag*

A tag for a definition created (or used) in the context of a function.

**__init__**(*function=None*, *metadata=None*)

**Parameters**

- **function** (*int | None*)
- **metadata** (*object*)

class angr.knowledge_plugins.key_definitions.tag.**SideEffectTag**

Bases: *FunctionTag*

A tag for a definition created or used as a side-effect of a function.

Example: The <MemoryLocation> pointed by *rdi* during a *sprintf*.

class angr.knowledge_plugins.key_definitions.tag.**ParameterTag**

Bases: *FunctionTag*

A tag for a definition of a parameter.

class angr.knowledge_plugins.key_definitions.tag.**LocalVariableTag**

Bases: *FunctionTag*

A tag for a definition of a local variable of a function.

class angr.knowledge_plugins.key_definitions.tag.**ReturnValueTag**

Bases: *FunctionTag*

A tag for a definition of a return value of a function.

class angr.knowledge_plugins.key_definitions.tag.**InitialValueTag**

Bases: *Tag*

A tag for a definition of an initial value

class angr.knowledge_plugins.key_definitions.tag.**UnknownSizeTag**

Bases: *Tag*

A tag for a definition of an initial value

### angr.knowledge_plugins.key_definitions.undefined

class angr.knowledge_plugins.key_definitions.undefined.**Undefined**

Bases: object

A TOP-like value indicating an unknown data source. Should live next to raw integers in DataSets.

### angr.knowledge_plugins.key_definitions.unknown_size

class angr.knowledge_plugins.key_definitions.unknown_size.**UnknownSize**

Bases: object

A value indicating an unknown size for elements of DataSets. Should "behave" like an integer.

### angr.knowledge_plugins.key_definitions.uses

class angr.knowledge_plugins.key_definitions.uses.**Uses**

Bases: object

Describes uses (including the use location and the use expression) for definitions.

**__init__**(*uses_by_definition=None*, *uses_by_location=None*)

**Parameters**

- **uses_by_definition** (DefaultChainMapCOW | *None*)
- **uses_by_location** (DefaultChainMapCOW | *None*)

**add_use**(*definition*, *codeloc*, *expr=None*)

Add a use for a given definition.

**Parameters**

- **definition** (*Definition*) – The definition that is used.
- **codeloc** (*CodeLocation*) – The code location where the use occurs.
- **expr** (Any | None) – The expression that uses the specified definition at this location.

**get_uses**(*definition*)

Retrieve the uses of a given definition.

**Parameters**
**definition** (*Definition*) – The definition for which we get the uses.

**Return type**
set[*CodeLocation*]

**get_uses_with_expr**(*definition*)

Retrieve the uses and the corresponding expressions of a given definition.

**Parameters**
**definition** (*Definition*) – The definition for which we get the uses and the corresponding expressions.

**Return type**
set[tuple[*CodeLocation*, Any | None]]

**remove_use**(*definition*, *codeloc*, *expr=None*)

Remove one use of a given definition.

**Parameters**

- **definition** (*Definition*) – The definition of which to remove the uses.
- **codeloc** (*CodeLocation*) – The code location where the use is.
- **expr** (Any | None) – The expression that uses the definition at the given location.

**Return type**
None

**Returns**
None

**remove_uses**(*definition*)

Remove all uses of a given definition.

**Parameters**
**definition** (*Definition*) – The definition of which to remove the uses.

**Returns**
None

**get_uses_by_location**(*codeloc*, *exprs=False*)

Retrieve all definitions that are used at a given location.

**Parameters**

- **codeloc** (*CodeLocation*) – The code location.
- **exprs** (*bool*)

**Return type**
set[*Definition*] | set[tuple[*Definition*, Any | None]]

**Returns**
A set of definitions that are used at the given location.

**get_uses_by_insaddr**(*ins_addr*, *exprs=False*)

Retrieve all definitions that are used at a given location specified by the instruction address.

**Parameters**

- **ins_addr** (int) – The instruction address.
- **exprs** (*bool*)

**Return type**
set[*Definition*] | set[tuple[*Definition*, Any | None]]

**Returns**
A set of definitions that are used at the given location.

**copy**()

Copy the instance.

**Return type**
*Uses*

**Returns**
Return a new <Uses> instance containing the same data.

**merge**(*other*)

Merge an instance of <Uses> into the current instance.

**Parameters**
**other** (*Uses*) – The other <Uses> from which the data will be added to the current instance.

**Return type**
bool

**Returns**
True if any merge occurred, False otherwise

### 10.24.11 angr.knowledge_plugins.labels

**class** angr.knowledge_plugins.labels.**Labels**

Bases: *KnowledgeBasePlugin*

**__init__**(*kb*)

**items**()

**get**(*addr*, *default=None*)

Get a label as string for a given address Same as .labels[x]

**lookup**(*name*, *default=None*)

Returns an address to a given label To show all available labels, iterate over .labels or list(b.kb.labels)

**copy**()

**get_unique_label**(*label*)

Get a unique label name from the given label name.

**Parameters**
**label** (*str*) – The desired label name.

**Returns**
A unique label name.

### 10.24.12 angr.knowledge_plugins.obfuscations

**class** angr.knowledge_plugins.obfuscations.**Obfuscations**

Bases: *KnowledgeBasePlugin*

Store discovered information and artifacts about (string) obfuscation techniques in the project.

**__init__**(*kb*)

**copy**()

### 10.24.13 angr.knowledge_plugins.patches

**class** angr.knowledge_plugins.patches.**Patch**

Bases: object

**__init__**(*addr*, *new_bytes*, *comment=None*)

**Parameters**
**comment** (*str | None*)

**class** angr.knowledge_plugins.patches.**PatchManager**

Bases: *KnowledgeBasePlugin*

A placeholder-style implementation for a binary patch manager. This class should be significantly changed in the future when all data about loaded binary objects are loaded into angr knowledge base from CLE. As of now, it only stores byte-level replacements.

Patches should not overlap, but it's user's responsibility to check for and avoid overlapping patches.

**__init__**(*kb*)

**has_patches**()

**Return type**
bool

**add_patch**(*addr*, *new_bytes*, *comment=None*)

**Parameters**
**comment** (*str | None*)

**add_patch_obj**(*patch*)

**Parameters**
**patch** (Patch)

**remove_patch**(*addr*)

**patch_addrs**()

**get_patch**(*addr*)

Get patch at the given address.

**Parameters**
**addr** (*int*) – The address of the patch.

**Returns**
The patch if there is one starting at the address, or None if there isn't any.

**Return type**
*Patch* or None

**get_all_patches**(*addr*, *size*)

Retrieve all patches that cover a region specified by [addr, addr+size).

**Parameters**

- **addr** (*int*) – The address of the beginning of the region.
- **size** (*int*) – Size of the region.

**Returns**
A list of patches.

**Return type**
list

**keys**()

**items**()

**values**()

**copy**()

**static overlap**(*a0*, *a1*, *b0*, *b1*)

**apply_patches_to_binary**(*binary_bytes=None*, *patches=None*)

**Return type**
bytes

**Parameters**

- **binary_bytes** (bytes | *None*)
- **patches** (*list[Patch]* | *None*)

**apply_patches_to_state**(*state*)

**property patched_entry_state**

### 10.24.14 angr.knowledge_plugins.patterns

User-authored fuzzy patterns, kept with the knowledge base so they outlive a session.

A stored pattern is a KnownPattern plus how it is to be applied: whether it is switched on, and the similarity an occurrence must reach before it is outlined. Patterns are keyed by name; call names are unique too, since an outlined call is looked up by its target.

class angr.knowledge_plugins.patterns.**PatternStats**

Bases: object

What the outliner pass saw of one pattern in one function when it last ran there.

**matches:** int = 0

verified occurrences found before anything was outlined

**outlined:** int = 0

occurrences outlined into calls

**call_addrs:** list[int]

the instruction address each outlined call carries, which is where it renders

**match_addrs:** list[frozenset[int]]

for each verified occurrence, the instruction addresses its statements carry

**__init__**(*matches=0*, *outlined=0*, *call_addrs=<factory>*, *match_addrs=<factory>*)

**Parameters**

- **matches** (*int*)
- **outlined** (*int*)
- **call_addrs** (*list[int]*)
- **match_addrs** (*list[frozenset[int]]*)

**Return type**
None

class angr.knowledge_plugins.patterns.**StoredPattern**

Bases: object

One fuzzy pattern and its application settings.

**pattern:** *KnownPattern*

**enabled:** bool = True

**min_similarity:** float = 0.8

an occurrence is outlined only at this similarity or above (see search.TemplateMatch)

**origin_func:** int | None = None

address of the function the pattern was lifted from, if any

**require_verified:** bool = True

outline only occurrences that pass the pattern's structural match (constants, captures); off, similarity alone decides, as it does for discovered patterns

**created_at:** float

**property name:** str

**to_dict**()

**Return type**
dict[str, Any]

**classmethod from_dict**(*data*)

**Return type**
*StoredPattern*

**Parameters**
**data** (*dict[str, Any]*)

**__init__**(*pattern*, *enabled=True*, *min_similarity=0.8*, *origin_func=None*, *require_verified=True*, *created_at=<factory>*)

**Parameters**

- **pattern** (KnownPattern)
- **enabled** (*bool*)
- **min_similarity** (*float*)
- **origin_func** (*int | None*)
- **require_verified** (*bool*)
- **created_at** (*float*)

**Return type**
None

**class** angr.knowledge_plugins.patterns.**Patterns**

Bases: *KnowledgeBasePlugin*

The fuzzy patterns of a knowledge base, by pattern name.

**__init__**(*kb*)

**Parameters**
**kb** (KnowledgeBase)

**copy**()

**Return type**
*Patterns*

**record_stats**(*func_addr*, *stats*)

Replace what is known about func_addr: the outliner pass saw exactly these patterns.

**Return type**
None

**Parameters**

- **func_addr** (*int*)
- **stats** (*dict[str, PatternStats]*)

**stats**(*func_addr*, *name*)

The outliner pass's numbers for a pattern in a function, or None if it did not search for that pattern there when it last ran.

**Return type**
*PatternStats* | None

**Parameters**

- **func_addr** (*int*)

- **name** (*str*)

**get**(*name*)

**Return type**
*StoredPattern* | None

**Parameters**
**name** (*str*)

**add**(*pattern*, ***, *enabled=True*, *min_similarity=0.8*, *origin_func=None*, *require_verified=True*, *replace=False*)

Store `pattern`. Refuses a name or call name already taken unless `replace`.

**Return type**
*StoredPattern*

**Parameters**

- **pattern** (KnownPattern)
- **enabled** (*bool*)
- **min_similarity** (*float*)
- **origin_func** (*int | None*)
- **require_verified** (*bool*)
- **replace** (*bool*)

**store**(*stored*)

Put a StoredPattern back, keeping its settings (a loader's entry point).

**Return type**
None

**Parameters**
**stored** (StoredPattern)

**remove**(*name*)

**Return type**
bool

**Parameters**
**name** (*str*)

**set_enabled**(*name*, *enabled*)

**Return type**
None

**Parameters**

- **name** (*str*)
- **enabled** (*bool*)

**enabled_patterns**()

**Return type**
list[*StoredPattern*]

**by_call_name**(*call_name*)

**Return type**
*StoredPattern* | None

**Parameters**
**call_name** (*str*)

**to_records**()

**Return type**
list[dict[str, Any]]

**load_records**(*records*)

**Return type**
None

**Parameters**
**records** (*list[dict[str, Any]]*)

### 10.24.15 angr.knowledge_plugins.plugin

**class** angr.knowledge_plugins.plugin.**KnowledgeBasePlugin**

Bases: object

**__init__**(*kb*)

**Parameters**
**kb** (KnowledgeBase)

**copy**()

**set_kb**(*kb*)

Invoked after __setstate__() is called.

**Parameters**
**kb** (KnowledgeBase)

**static register_default**(*name*, *cls*)

### 10.24.16 angr.knowledge_plugins.propagations

**class** angr.knowledge_plugins.propagations.**PropagationManager**

Bases: *KnowledgeBasePlugin*

Manages the results of Propagator, including intermediate results for unfinished Propagation runs.

**__init__**(*kb*)

**exists**(*prop_key*)

Internal function to check if a func, specified as a CodeLocation exists in our known propagations

**Parameters**
**prop_key** (tuple) – A key of the propagation result.

**Return type**
bool

**Returns**
Whether such a key exists or not.

**update**(*prop_key*, *model*)

Add the replacements to known propagations

**Parameters**

- **prop_key** (tuple) – A key of the propagation result.
- **model** (*PropagationModel*) – The propagation result to store

**Return type**
None

**get**(*prop_key*, *default=None*)

Gets the replacements for a specified function location. If the replacement does not exist in the known propagations, it returns None.

**Parameters**

- **prop_key** – A key of the propagation result.
- **default** – The default value to return if the prop_key does not exist in the cache.

**Return type**
*PropagationModel*

**Returns**
Dict or None

**copy**()

**discard_by_prefix**(*prefix*)

**Parameters**
**prefix** (*str*)

class angr.knowledge_plugins.propagations.**PropagationModel**

Bases: *Serializable*

This class stores the propagation result that comes out of Propagator.

**__init__**(*prop_key*, *node_iterations=None*, *states=None*, *block_initial_reg_values=None*, *replacements=None*, *equivalence=None*, *function=None*, *input_states=None*, *function_block_count=None*)

**Parameters**

- **prop_key** (*tuple*)
- **node_iterations** (*defaultdict[Any, int] | None*)
- **states** (*dict | None*)
- **block_initial_reg_values** (*dict | None*)
- **replacements** (*defaultdict[Any, dict] | None*)
- **equivalence** (*set | None*)
- **function** (Function | *None*)
- **input_states** (*dict | None*)
- **function_block_count** (*int | None*)

**key**

**node_iterations**

**input_states**

**states**

**block_initial_reg_values**

**replacements**

**equivalence**

**graph_visitor**

**function_block_count**

**downsize**()

**block_beginning_state**(*block_addr*)

**Return type**
*PropagatorState*

### Submodules

*prop_value*
*propagation_manager*
*propagation_model*
*states*

### angr.knowledge_plugins.propagations.prop_value

**class** angr.knowledge_plugins.propagations.prop_value.**Detail**

Bases: object

A companion class used together with PropValue. It describes stored information at each offset (in bytes).

**Variables**
**def_at** – Where this expression is defined, or None if it was never explicitly defined in the current block or the current function.

**__init__**(*size*, *expr*, *def_at*)

**Parameters**

- **size** (*int*)
- **expr** (*ailment.Expression | None*)
- **def_at** (CodeLocation | *None*)

**size**

**expr**

**def_at**

**class** angr.knowledge_plugins.propagations.prop_value.**PropValue**

Bases: object

Describes immutable basic value type that is used in Propagator.

**__init__**(*value*, *offset_and_details=None*)

**Parameters**

- **value** (*Bits*)
- **offset_and_details** (*dict[int, Detail] | None*)

**value**

**offset_and_details**

**property needs_details**

**property one_expr:** *Expression* | None

Get the expression that starts at offset 0 and covers the entire PropValue. Returns None if there are no expressions or multiple expressions.

**property one_defat:** *CodeLocation* | None

Get the definition location of the expression that starts at offset 0 and covers the entire PropValue. Returns None if there are no expressions or multiple expressions.

**to_label**()

**with_details**(*size*, *expr*, *def_at*)

**Return type**
*PropValue*

**Parameters**

- **size** (*int*)
- **expr** (*ailment.Expression*)
- **def_at** (CodeLocation)

**all_exprs**()

**Return type**
Generator[*Expression*]

**non_zero_exprs**()

**Return type**
Generator[*Expression*]

**static chop_value**(*value*, *begin_offset*, *end_offset*)

**Return type**
Bits

**Parameters**
**value** (*Bits*)

**value_and_labels**()

**Return type**
Generator[tuple[int, Bits, int, dict | None]]

**static from_value_and_labels**(*value*, *labels*)

**Return type**
*PropValue*

**Parameters**

- **value** (*Bits*)
- **labels** (*Iterable[tuple[int, int, int, dict[str, Any]]]*)

**static from_value_and_details**(*value*, *size*, *expr*, *def_at*)

**Parameters**

- **value** (*claripy.ast.Bits*)
- **size** (*int*)
- **expr** (*ailment.Expression*)
- **def_at** (CodeLocation)

**static extract_ail_expression**(*start*, *bits*, *expr*)

**Return type**
*Expression* | None

**Parameters**

- **start** (*int*)
- **bits** (*int*)
- **expr** (*Expression | None*)

**static extend_ail_expression**(*bits*, *expr*)

**Return type**
*Expression* | None

**Parameters**

- **bits** (*int*)
- **expr** (*Expression | None*)

### angr.knowledge_plugins.propagations.propagation_manager

**class** angr.knowledge_plugins.propagations.propagation_manager.**PropagationManager**

Bases: *KnowledgeBasePlugin*

Manages the results of Propagator, including intermediate results for unfinished Propagation runs.

**__init__**(*kb*)

**exists**(*prop_key*)

Internal function to check if a func, specified as a CodeLocation exists in our known propagations

**Parameters**
**prop_key** (tuple) – A key of the propagation result.

**Return type**
bool

**Returns**
Whether such a key exists or not.

**update**(*prop_key*, *model*)

Add the replacements to known propagations

**Parameters**

- **prop_key** (tuple) – A key of the propagation result.
- **model** (*PropagationModel*) – The propagation result to store

**Return type**
None

**get**(*prop_key*, *default=None*)

Gets the replacements for a specified function location. If the replacement does not exist in the known propagations, it returns None.

**Parameters**

- **prop_key** – A key of the propagation result.
- **default** – The default value to return if the prop_key does not exist in the cache.

**Return type**
*PropagationModel*

**Returns**
Dict or None

**copy**()

**discard_by_prefix**(*prefix*)

**Parameters**
**prefix** (*str*)

### angr.knowledge_plugins.propagations.propagation_model

**class** angr.knowledge_plugins.propagations.propagation_model.**PropagationModel**

Bases: *Serializable*

This class stores the propagation result that comes out of Propagator.

**__init__**(*prop_key*, *node_iterations=None*, *states=None*, *block_initial_reg_values=None*, *replacements=None*, *equivalence=None*, *function=None*, *input_states=None*, *function_block_count=None*)

**Parameters**

- **prop_key** (*tuple*)
- **node_iterations** (*defaultdict[Any, int] | None*)
- **states** (*dict | None*)
- **block_initial_reg_values** (*dict | None*)
- **replacements** (*defaultdict[Any, dict] | None*)
- **equivalence** (*set | None*)
- **function** (Function | *None*)

- **input_states** (*dict | None*)
- **function_block_count** (*int | None*)

**key**

**node_iterations**

**input_states**

**states**

**block_initial_reg_values**

**replacements**

**equivalence**

**graph_visitor**

**function_block_count**

**downsize**()

**block_beginning_state**(*block_addr*)

**Return type**
*PropagatorState*

### angr.knowledge_plugins.propagations.states

**class** angr.knowledge_plugins.propagations.states.**CallExprFinder**

Bases: *AILBlockRewriter*

Walks an AIL expression to find if it contains a call expression anywhere.

**__init__**()

**class** angr.knowledge_plugins.propagations.states.**PropagatorState**

Bases: object

Describes the base state used in Propagator.

**Variables**

- **arch** – Architecture of the binary.
- **gp** – value of the global pointer for MIPS binaries.
- **_replacements** – Stores expressions to replace, keyed by CodeLocation instances
- **_only_consts** – Only track constants.
- **_expr_used_locs** – A dict keyed by expressions and valued by CodeLocations where the expression is used.
- **_max_prop_expr_occurrence** – The upperbound for the number of occurrences of an expression for Propagator to propagate that expression to new locations (and replace the original expression). Setting it to 0 disables this limit, which means Propagator will always propagate expressions regardless of how many times it has been propagated.

__init__(*arch*, *project=None*, *replacements=None*, *only_consts=False*, *expr_used_locs=None*, *store_tops=True*, *gp=None*, *max_prop_expr_occurrence=1*, *model=None*, *artificial_reg_offsets=None*)

**Parameters**

- **arch** (*Arch*)
- **project** (*Project | None*)
- **replacements** (*defaultdict[CodeLocation, dict] | None*)
- **only_consts** (*bool*)
- **expr_used_locs** (*defaultdict[Any, set[CodeLocation]] | None*)
- **store_tops** (*bool*)
- **gp** (*int | None*)
- **max_prop_expr_occurrence** (*int*)

**arch**

**gpr_size**

**project**

**model**

**classmethod initial_state**(*project*, *only_consts=False*, *gp=None*, *do_binops=True*, *store_tops=False*, *func_addr=None*, *max_prop_expr_occurrence=None*, *initial_codeloc=None*)

**Parameters**
**project** (*Project*)

**static top**(*bits*)

Get a TOP value.

**Parameters**

- **size** – Width of the TOP value (in bits).
- **bits** (*int*)

**Return type**
BV

**Returns**
The TOP value.

**static is_top**(*expr*)

Check if the given expression is a TOP value.

**Parameters**
**expr** – The given expression.

**Return type**
bool

**Returns**
True if the expression is TOP, False otherwise.

**static merge_replacements**(*replacements_0*, *replacements_1*)

The replacement merging logic is special: replacements_1 is the newer replacement result and replacement_0 is the older result waiting to be updated. When both replacements_1 and replacement_0 have a non-top value for the same variable and code location, we will update the slot in replacement_0 with the value from replacement_1.

**Return type**
bool

**Returns**
Whether merging has happened or not.

**abstractmethod copy**()

**Return type**
Self

**merge**(**others*)

**Return type**
tuple[Self, bool]

**Parameters**
**others** (*Self*)

**init_replacements**()

**add_replacement**(*codeloc*, *old*, *new*, *force_replace=False*)

Add a replacement record: Replacing expression *old* with *new* at program location *codeloc*. If the self._only_consts flag is set to true, only constant values will be set.

**Parameters**

- **codeloc** (*CodeLocation*) – The code location.
- **old** – The expression to be replaced.
- **new** – The expression to replace with.
- **force_replace** (*bool*)

**Return type**
bool

**Returns**
True if the replacement will happen. False otherwise.

**filter_replacements**()

**has_replacements_at**(*codeloc*)

**Return type**
bool

**Parameters**
**codeloc** (CodeLocation)

**class** angr.knowledge_plugins.propagations.states.**RegisterAnnotation**

Bases: Annotation

Annotates TOP values that are coming from registers.

**eliminatable = True**

relocatable = True

__init__(*offset*, *size*)

class angr.knowledge_plugins.propagations.states.**RegisterComparisonAnnotation**

Bases: Annotation

Annotate TOP values that are the result of register values comparing against constant values.

eliminatable = True

relocatable = True

__init__(*offset*, *size*, *cmp_op*, *value*)

**Parameters**

- **offset** (*int*)
- **size** (*int*)
- **cmp_op** (*str*)
- **value** (*int*)

class angr.knowledge_plugins.propagations.states.**PropagatorVEXState**

Bases: *PropagatorState*

Describes the state used in the VEX engine of Propagator.

__init__(*arch*, *project=None*, *registers=None*, *local_variables=None*, *replacements=None*, *only_consts=False*, *expr_used_locs=None*, *do_binops=True*, *store_tops=True*, *block_initial_reg_values=None*, *gp=None*, *max_prop_expr_occurrence=1*, *model=None*, *artificial_reg_offsets=None*)

**Parameters**

**max_prop_expr_occurrence** (*int*)

do_binops

block_initial_reg_values

classmethod initial_state(*project*, *only_consts=False*, *gp=None*, *do_binops=True*, *store_tops=False*, *func_addr=None*, *max_prop_expr_occurrence=None*, *initial_codeloc=None*, *model=None*)

copy()

**Return type**

*PropagatorVEXState*

merge(**others*)

**Return type**

tuple[*PropagatorVEXState*, bool]

**Parameters**

**others** (PropagatorVEXState)

store_local_variable(*offset*, *size*, *value*, *endness*)

load_local_variable(*offset*, *size*, *endness*)

**Return type**
BV

store_register(*offset*, *size*, *value*)

load_register(*offset*, *size*)

register_results()

**Return type**
dict[str, BV]

class angr.knowledge_plugins.propagations.states.**Equivalence**

Bases: object

Describes an equivalence relationship between two atoms.

__init__(*codeloc*, *atom0*, *atom1*, *is_weakassignment=False*)

**Parameters**
**is_weakassignment** (*bool*)

codeloc

atom0

atom1

is_weakassignment

### 10.24.17 angr.knowledge_plugins.rtdb

class angr.knowledge_plugins.rtdb.**RuntimeDb**

Bases: *KnowledgeBasePlugin*

External storage-backed database for angr knowledge base plugins.

__init__(*kb*, *lmdb_path=None*)

**Parameters**
- **kb** (KnowledgeBase)
- **lmdb_path** (*str | None*)

**Return type**
None

increase_lmdb_map_size()

Increase the LMDB map size. Returns False when there is no environment to grow (callers must not retry).

Note that the old database handle *may* no longer be valid after a map size increase. rhelmot could reproduce the error "Database handle belongs to another environment." in nix + CPython 3.13.13. Reopening all databases after increasing LMDB map size solves this issue.

**Return type**
bool

reopen_lmdb()

Reopen the existing LMDB environment and all open databases in self._dbs.

**reopen_lmdb_databases**()

**open_db**(*db_name*, *unique=True*)

**Return type**
str

**Parameters**

- **db_name** (*str*)
- **unique** (*bool*)

**begin_txn**(*db_name*, *write=False*)

**Parameters**

- **db_name** (*str*)
- **write** (*bool*)

**drop_db**(*db_name*)

**Return type**
None

**Parameters**
**db_name** (*str*)

**cleanup**()

Close the LMDB environment and remove the rtdb directory if this is the last user of it. This method may be invoked multiple times (e.g., once by the atexit hook and once more by __del__) and should not fail.

## Submodules

*rtdb*

### angr.knowledge_plugins.rtdb.rtdb

**class** angr.knowledge_plugins.rtdb.rtdb.**RuntimeDbForkCondom**

Bases: object

A class that invokes RuntimeDb.reopen_lmdb() upon forking. This is necessary to ensure that lmdb does not raise ReaderFullError in forked child processes. The reopen_rtdb() method is not called on Windows because os.register_at_fork does not exist on Windows.

**__init__**(*rtdb*)

**Parameters**
**rtdb** (RuntimeDb)

**reopen_rtdb**()

**class** angr.knowledge_plugins.rtdb.rtdb.**RuntimeDb**

Bases: *KnowledgeBasePlugin*

External storage-backed database for angr knowledge base plugins.

**__init__**(*kb*, *lmdb_path=None*)

**Parameters**

- **kb** (KnowledgeBase)
- **lmdb_path** (*str | None*)

**Return type**
None

**increase_lmdb_map_size**()

Increase the LMDB map size. Returns False when there is no environment to grow (callers must not retry).

Note that the old database handle *may* no longer be valid after a map size increase. rhelmot could reproduce the error "Database handle belongs to another environment." in nix + CPython 3.13.13. Reopening all databases after increasing LMDB map size solves this issue.

**Return type**
bool

**reopen_lmdb**()

Reopen the existing LMDB environment and all open databases in self._dbs.

**reopen_lmdb_databases**()

**open_db**(*db_name*, *unique=True*)

**Return type**
str

**Parameters**

- **db_name** (*str*)
- **unique** (*bool*)

**begin_txn**(*db_name*, *write=False*)

**Parameters**

- **db_name** (*str*)
- **write** (*bool*)

**drop_db**(*db_name*)

**Return type**
None

**Parameters**
**db_name** (*str*)

**cleanup**()

Close the LMDB environment and remove the rtdb directory if this is the last user of it. This method may be invoked multiple times (e.g., once by the atexit hook and once more by __del__) and should not fail.

### 10.24.18 angr.knowledge_plugins.structured_code

**class** angr.knowledge_plugins.structured_code.**SpillingDecompilationDict**

Bases: MutableMapping

A dict of decompilation caches, keyed by (function address, flavor), that keeps only the most recently used cache_limit entries in memory and spills the rest to an LMDB database managed by the RuntimeDb knowledge base plugin.

Evicted entries are always serialized and written out (caches are mutated in place, so there is no clean/dirty distinction). Entries that cannot be serialized (e.g. DummyStructuredCodeGenerator or rust-flavor caches) are parked in an unbounded in-memory dict. Spilled entries are deserialized on access with the owning knowledge base's project/function attached.

**__init__**(*kb*, *cache_limit=128*)

**Parameters**

- **kb** (KnowledgeBase)
- **cache_limit** (*int*)

**property cache_limit: int**

**export_serialized**()

Export all serializable entries as (key, serialized bytes) pairs. Spilled entries are copied directly out of the LMDB backing store without being deserialized and re-serialized. Entries that cannot be serialized are returned separately in a dict.

**Return type**
tuple[list[tuple[tuple[int, str], bytes]], dict[tuple[int, str], *DecompilationCache*]]

**bulk_import_serialized**(*items*)

Move already-serialized decompilation caches directly into the LMDB backing store and register them as spilled, without deserializing them. The bytes must be serialized DecompilationCache messages, i.e., the exact format that eviction writes.

**Return type**
None

**Parameters**
**items** (*list[tuple[tuple[int, str], bytes]]*)

**class** angr.knowledge_plugins.structured_code.**StructuredCodeManager**

Bases: *KnowledgeBasePlugin*

A knowledge base plugin to store structured code generator results.

**__init__**(*kb*, *cache_limit=None*)

**Parameters**
**cache_limit** (*int | None*)

**get**(*key*, *default=None*)

**discard**(*key*)

**available_flavors**(*item*)

**all_flavors**(*item*)

**copy**()

## 10.24.19 angr.knowledge_plugins.types

class angr.knowledge_plugins.types.**TypesStore**

Bases: *KnowledgeBasePlugin*, UserDict[str, *TypeRef*]

A kb plugin that stores a mapping from name to TypeRef. It will return types from angr.sim_type.ALL_TYPES as a default.

**__init__**(*kb*)

**copy**(*kb=None*)

Copy the store's own entries (not ALL_TYPES) into a new store for kb (default: the same knowledge base). Each entry gets a new TypeRef pointing at the same target type.

**Return type**
*TypesStore*

**Parameters**
**kb** (KnowledgeBase | *None*)

**get_own**(*item*)

**Return type**
*TypeRef*

**Parameters**
**item** (*str*)

**iter_own**()

Iterate over all the names which are stored in this object - i.e. values() without ALL_TYPES

**iter_own_keys**()

**rename**(*old*, *new*)

**Parameters**

- **old** (*str*)
- **new** (*str*)

**unique_type_name**()

**Return type**
str

## 10.24.20 angr.knowledge_plugins.variables

class angr.knowledge_plugins.variables.**DecompilationVariableManager**

Bases: *VariableManager*

Holds variables discovered during decompilation, kept separate from the disassembly-level kb.variables. Exposed as kb.dec_variables. Per-function managers are held in a SpillingVariableInternalDict, which spills least-recently-used entries to the RuntimeDb LMDB store (disable via USE_SPILLING_DVARS).

**__init__**(*kb*)

class angr.knowledge_plugins.variables.**VariableManager**

Bases: *KnowledgeBasePlugin*

Manage variables.

**__init__**(*kb*)

global_managers: dict[str, *VariableManagerInternal*]

function_managers: dict[int, *VariableManagerInternal*] | *SpillingVariableInternalDict*

property global_manager: *VariableManagerInternal*

The global manager of the default flavor. Code with no decompilation flavor (CFG, DWARF, SimProcedures) uses it.

get_global_manager(*flavor*)

The global manager that a decompilation of the given flavor (None means the default flavor) reads and writes. A new flavor starts empty: global names are re-derived from labels, types are re-inferred.

**Return type**
*VariableManagerInternal*

**Parameters**
**flavor** (*str | None*)

set_global_manager(*flavor*, *manager*)

**Return type**
None

**Parameters**

- **flavor** (*str | None*)
- **manager** (VariableManagerInternal)

has_function_manager(*key*)

**Return type**
bool

**Parameters**
**key** (*int*)

has_function_manager_for_flavor(*key*, *flavor*)

Whether a function manager exists and can be reused by a decompilation of the given flavor. A manager of unknown flavor (None) is compatible with any flavor.

**Return type**
bool

**Parameters**

- **key** (*int*)
- **flavor** (*str*)

get_function_manager(*func_addr*)

**Return type**
*VariableManagerInternal*

initialize_variable_names()

**Return type**
None

**get_variable_accesses**(*variable*, *same_name=False*)

Get a list of all references to the given variable.

**Parameters**

- **variable** (*SimVariable*) – The variable.
- **same_name** (bool) – Whether to include all variables with the same variable name, or just based on the variable identifier.

**Return type**
list[*VariableAccess*]

**Returns**
All references to the variable.

**copy**()

**Return type**
*VariableManager*

**static convert_variable_list**(*vlist*, *manager*)

**Parameters**

- **vlist** (*list[Variable]*)
- **manager** (VariableManagerInternal)

**load_from_dwarf**(*cu_list=None*)

**Parameters**
**cu_list** (*list[CompilationUnit] | None*)

**class** angr.knowledge_plugins.variables.**VariableType**

Bases: object

Describes variable types.

**REGISTER = 0**

**MEMORY = 1**

## Submodules

*spilling_vardict*
*variable_access*
*variable_manager*

### angr.knowledge_plugins.variables.spilling_vardict

**class** angr.knowledge_plugins.variables.spilling_vardict.**SpillingVariableInternalDict**

Bases: MutableMapping

A dict of per-function VariableManagerInternal instances (keyed by function address) that keeps only the most recently used cache_limit entries in memory and spills the rest to an LMDB database managed by the RuntimeDb knowledge base plugin. It is the backing store for `DecompilationVariableManager.function_managers`.

Evicted entries are serialized and written out; they are deserialized on access with the owning manager reattached. Decompilation only mutates a function's internal manager while decompiling that function (when it is the most-

recently-used entry) and treats it as read-only afterwards, so spilling is safe.

On pickle, the serialized entries travel inside the pickle and are re-imported into a fresh LMDB on first access after unpickling.

**__init__**(*manager*, *cache_limit=1000*)

**Parameters**

- **manager** (DecompilationVariableManager)
- **cache_limit** (*int*)

**property cache_limit: int**

**bulk_import_serialized**(*items*)

Move already-serialized function managers in a VariableManager straight into LMDB and register them as spilled.

**Return type**
None

**Parameters**
**items** (*list[tuple[int, bytes]]*)

### angr.knowledge_plugins.variables.variable_access

**class** angr.knowledge_plugins.variables.variable_access.**VariableAccessSort**

Bases: object

Provides enums for variable access types.

**WRITE = 0**

**READ = 1**

**REFERENCE = 2**

**class** angr.knowledge_plugins.variables.variable_access.**VariableAccess**

Bases: *Serializable*

Describes a variable access.

**__init__**(*variable*, *access_type*, *location*, *offset*, *atom_hash=None*)

**variable: *SimVariable***

**access_type: int**

**location: *CodeLocation***

**offset: int | None**

**atom_hash: int | None**

### angr.knowledge_plugins.variables.variable_manager

**class** angr.knowledge_plugins.variables.variable_manager.**VariableType**

Bases: object

Describes variable types.

**REGISTER = 0**

**MEMORY = 1**

**class** angr.knowledge_plugins.variables.variable_manager.**LiveVariables**

Bases: object

A collection of live variables at a program point.

**__init__**(*register_region*, *stack_region*)

**register_region**

**stack_region**

**class** angr.knowledge_plugins.variables.variable_manager.**VariableManagerInternal**

Bases: *Serializable*

Manage variables for a function. It is meant to be used internally by VariableManager, but it's common to be given a reference to one in response to a query for "the variables for a given function". Maybe a better name would be "VariableManagerScope".

**__init__**(*manager*, *func_addr=None*)

**manager:** *VariableManager*

**flavor:** str | None

**variable_to_types:** dict[*SimVariable*, *SimType*]

**array_length_exprs:** dict[*SimVariable*, *Expression*]

**copy**(*manager*)

Clone this manager for `manager`. Every `SimVariable` is copied, so renaming or retyping a variable in one manager does not affect the other; types, variable accesses' code locations and AIL expressions are shared.

**Return type**
*VariableManagerInternal*

**Parameters**
**manager** (VariableManager)

**set_manager**(*manager*)

**Parameters**
**manager** (VariableManager)

**next_variable_ident**(*sort*)

**add_variable**(*sort*, *start*, *variable*)

**Parameters**
**variable** (SimVariable)

**set_variable**(*sort*, *start*, *variable*)

**Parameters**
**variable** (SimVariable)

**write_to**(*variable*, *offset*, *location*, *overwrite=False*, *atom=None*)

**read_from**(*variable*, *offset*, *location*, *overwrite=False*, *atom=None*)

**reference_at**(*variable*, *offset*, *location*, *overwrite=False*, *atom=None*)

**record_variable**(*location*, *variable*, *offset*, *overwrite=False*, *atom=None*)

**Parameters**

- **location** (CodeLocation)
- **offset** (*int | None*)
- **atom** (ailment.expression.Atom | *None*)

**remove_variable_by_atom**(*location*, *variable*, *atom*)

**Parameters**

- **location** (CodeLocation)
- **variable** (SimVariable)

**rebind_variable_records**(*old*, *new*)

Re-point every instruction, statement and atom record of *old* to *new*.

**Return type**
None

**Parameters**

- **old** (SimVariable)
- **new** (SimVariable)

**make_phi_node**(*block_addr*, **variables*)

Create a phi variable for variables at block *block_addr*.

**Parameters**

- **block_addr** (*int*) – The address of the current block.
- **variables** – Variables that the phi variable represents.

**Returns**
The created phi variable.

**set_live_variables**(*addr*, *register_region*, *stack_region*)

**find_variables_by_insn**(*ins_addr*, *sort*)

**is_variable_used_at**(*variable*, *loc*)

**Return type**
bool

**Parameters**

- **variable** (SimVariable)
- **loc** (*tuple[int, int]*)

**find_variable_by_stmt**(*block_addr*, *stmt_idx*, *sort*, *block_idx=None*)

**Parameters**
**block_idx** (*int | None*)

**find_variables_by_stmt**(*block_addr*, *stmt_idx*, *sort*, *block_idx=None*)

**Return type**
list[tuple[*SimVariable*, int | None]]

**Parameters**

- **block_addr** (*int*)
- **stmt_idx** (*int*)
- **sort** (*str*)
- **block_idx** (*int | None*)

**find_variable_by_atom**(*block_addr*, *stmt_idx*, *atom*, *block_idx=None*)

**Parameters**
**block_idx** (*int | None*)

**variable_by_vvar_id**(*varid*)

The variable that was assigned to the virtual variable with the given id, if any.

**Return type**
*SimVariable* | None

**Parameters**
**varid** (*int*)

**find_variables_by_atom**(*block_addr*, *stmt_idx*, *atom*, *block_idx=None*)

**Return type**
set[tuple[*SimVariable*, int | None]]

**Parameters**

- **atom** (Expression)
- **block_idx** (*int | None*)

**find_variables_by_stack_offset**(*offset*)

**Return type**
set[*SimVariable*]

**Parameters**
**offset** (*int*)

**find_variables_by_register**(*reg*)

**Return type**
set[*SimVariable*]

**Parameters**
**reg** (*str | int*)

**get_variable_accesses**(*variable*, *same_name=False*)

**Return type**
list[*VariableAccess*]

**Parameters**

- **variable** (SimVariable)
- **same_name** (*bool*)

`get_variables`(*sort=None*, *collapse_same_ident=False*)

Get a list of variables.

**Overloads**

- **sort** (`Literal['stack']`), **collapse_same_ident** (`bool`) = `False` → `list`[*SimStackVariable*]
- **sort** (`Literal['reg']`), **collapse_same_ident** (`bool`) = `False` → `list`[*SimRegisterVariable*]
- **sort** (`None`) = `None`, **collapse_same_ident** (`bool`) = `False` → `list`[*SimRegisterVariable*]

**Parameters**

- **sort** – Sort of the variable to get.
- **collapse_same_ident** – Whether variables of the same identifier should be collapsed or not.

**Returns**

A list of variables.

`get_unified_variables`(*sort=None*)

Get a list of unified variables.

**Overloads**

- **sort** (`Literal['stack']`) → `list`[*SimStackVariable*]
- **sort** (`Literal['reg']`) → `list`[*SimRegisterVariable*]
- **sort** (`None`) → `list`[*SimRegisterVariable*]

**Parameters**

**sort** – Sort of the variable to get.

**Returns**

A list of variables.

`get_global_variables`(*addr*)

Get global variable by the address of the variable.

**Parameters**

**addr** (*int*) – Address of the variable.

**Returns**

A set of variables or an empty set if no variable exists.

`is_phi_variable`(*var*)

Test if *var* is a phi variable.

**Parameters**

**var** (`SimVariable`) – The variable instance.

**Returns**

True if *var* is a phi variable, False otherwise.

**Return type**

bool

**get_phi_subvariables**(*var*)

Get sub-variables that phi variable *var* represents.

**Parameters**
**var** (SimVariable) – The variable instance.

**Returns**
A set of sub-variables, or an empty set if *var* is not a phi variable.

**Return type**
set

**get_phi_variables**(*block_addr*)

Get a dict of phi variables and their corresponding variables.

**Parameters**
**block_addr** (*int*) – Address of the block.

**Returns**
A dict of phi variables of an empty dict if there are no phi variables at the block.

**Return type**
dict

**get_variables_without_writes**()

Get all variables that have never been written to.

**Return type**
list[*SimVariable*]

**Returns**
A list of variables that are never written to.

**input_variables**(*exclude_specials=True*)

Get all variables that have never been written to.

**Returns**
A list of variables that are never written to.

**Parameters**
**exclude_specials** (*bool*)

**assign_variable_names**(*labels=None*, *types=None*)

Assign default names to all SSA variables.

**Parameters**
**labels** – Known labels in the binary.

**Returns**
None

**assign_unified_variable_names**(*labels=None*, *arg_names=None*, *reset=False*, *func_blocks=None*)

Assign default names to all unified variables. If *func_blocks* is provided, we will find out variables that are only ever written to in Phi assignments and never used elsewhere, and put these variables at the end of the sorted list. These variables are likely completely removed during the dephication process.

**Parameters**

- **labels** – Known labels in the binary.
- **arg_names** (list[str] | None) – Known argument names.
- **reset** (bool) – Reset all variable names or not.

- **func_blocks** (list[Block] | None) – A list of function blocks of the function where these variables are accessed.

**Return type**
None

**set_variable_type**(*var*, *ty*, *name=None*, *override_bot=True*, *all_unified=False*, *mark_manual=False*)

**Return type**
None

**Parameters**

- **var** (SimVariable)
- **ty** (SimType)
- **name** (*str | None*)
- **override_bot** (*bool*)
- **all_unified** (*bool*)
- **mark_manual** (*bool*)

**get_variable_type**(*var*)

**Return type**
*SimType* | None

**remove_types**()

**same_offset_stack_vvarids**()

Return the IDs of vvars backing stack variables that share their offset with another stack variable. These are the only vvars whose interference unify_variables() consults.

**Return type**
set[int]

**unify_variables**(*interference=None*)

Map SSA variables to a unified variable. Fill in self._unified_variables.

**Return type**
None

**Parameters**
**interference** (*networkx.Graph[int] | None*)

**set_unified_variable**(*variable*, *unified*)

Set the unified variable for a given SSA variable.

**Parameters**

- **variable** (*SimVariable*) – The SSA variable.
- **unified** (*SimVariable*) – The unified variable.

**Return type**
None

**Returns**
None

**unified_variable**(*variable*)

Return the unified variable for a given SSA variable,

**Parameters**
**variable** (*SimVariable*) – The SSA variable.

**Return type**
*SimVariable* | None

**Returns**
The unified variable, or None if there is no such SSA variable.

**get_stackvar_max_sizes**(*stack_items*)

Get the maximum size of each stack variable regardless of the type of each stack variable, under the assumption that stack variables do not overlap.

**Return type**
dict[*SimStackVariable*, int]

**Returns**
A dictionary from SimStackVariable to its maximum size.

**Parameters**
**stack_items** (*dict[int, StackItem]*)

**class** angr.knowledge_plugins.variables.variable_manager.**VariableManager**

Bases: *KnowledgeBasePlugin*

Manage variables.

**__init__**(*kb*)

**global_managers:** dict[str, *VariableManagerInternal*]

**function_managers:** dict[int, *VariableManagerInternal*] | *SpillingVariableInternalDict*

**property global_manager:** *VariableManagerInternal*

The global manager of the default flavor. Code with no decompilation flavor (CFG, DWARF, SimProcedures) uses it.

**get_global_manager**(*flavor*)

The global manager that a decompilation of the given flavor (None means the default flavor) reads and writes. A new flavor starts empty: global names are re-derived from labels, types are re-inferred.

**Return type**
*VariableManagerInternal*

**Parameters**
**flavor** (*str | None*)

**set_global_manager**(*flavor*, *manager*)

**Return type**
None

**Parameters**

- **flavor** (*str | None*)
- **manager** (VariableManagerInternal)

has_function_manager(*key*)

**Return type**
bool

**Parameters**
**key** (*int*)

has_function_manager_for_flavor(*key*, *flavor*)

Whether a function manager exists and can be reused by a decompilation of the given flavor. A manager of unknown flavor (None) is compatible with any flavor.

**Return type**
bool

**Parameters**

- **key** (*int*)
- **flavor** (*str*)

get_function_manager(*func_addr*)

**Return type**
*VariableManagerInternal*

initialize_variable_names()

**Return type**
None

get_variable_accesses(*variable*, *same_name=False*)

Get a list of all references to the given variable.

**Parameters**

- **variable** (*SimVariable*) – The variable.
- **same_name** (bool) – Whether to include all variables with the same variable name, or just based on the variable identifier.

**Return type**
list[*VariableAccess*]

**Returns**
All references to the variable.

copy()

**Return type**
*VariableManager*

static convert_variable_list(*vlist*, *manager*)

**Parameters**

- **vlist** (*list[Variable]*)
- **manager** (VariableManagerInternal)

load_from_dwarf(*cu_list=None*)

**Parameters**
**cu_list** (*list[CompilationUnit] | None*)

class angr.knowledge_plugins.variables.variable_manager.**DecompilationVariableManager**

Bases: *VariableManager*

Holds variables discovered during decompilation, kept separate from the disassembly-level `kb.variables`. Exposed as `kb.dec_variables`. Per-function managers are held in a `SpillingVariableInternalDict`, which spills least-recently-used entries to the RuntimeDb LMDB store (disable via `USE_SPILLING_DVARS`).

**__init__**(*kb*)

### 10.24.21 angr.knowledge_plugins.xrefs

class angr.knowledge_plugins.xrefs.**XRef**

Bases: *Serializable*

XRef describes a reference to a MemoryData instance (if a MemoryData instance is available) or just an address.

**__init__**(*ins_addr=None*, *block_addr=None*, *stmt_idx=None*, *insn_op_idx=None*, *memory_data=None*, *dst=None*, *xref_type=None*)

**Parameters**

- **ins_addr** (*int | None*)
- **block_addr** (*int | None*)
- **stmt_idx** (*int | None*)
- **insn_op_idx** (*int | None*)
- **memory_data** (*MemoryData | None*)
- **dst** (*int | None*)

**ins_addr:** int | None

**insn_op_idx:** int | None

**block_addr:** int | None

**stmt_idx:** int | None

**memory_data**

**type**

**dst**

**property type_string**

**insn_op_type**

**copy**()

class angr.knowledge_plugins.xrefs.**XRefManager**

Bases: *KnowledgeBasePlugin*, *Serializable*

**__init__**(*kb*)

**copy**()

**clear**()

**add_xref**(*xref*)

**add_xrefs**(*xrefs*)

**get_xrefs_by_ins_addr**(*ins_addr*)

**get_xrefs_by_dst**(*dst*)

**get_xrefs_by_dst_region**(*start*, *end*)

Get a set of XRef objects that point to a given address region bounded by start and end. Will only return absolute xrefs, not relative ones (like SP offsets)

**get_next_xref_addr_by_dst**(*addr*)

Get the next XRef object whose address is greater than or equal to the given address. Will only return absolute xrefs, not relative ones (like SP offsets)

**Return type**
int | None

**Parameters**
**addr** (*int*)

**get_xrefs_by_ins_addr_region**(*start*, *end*)

Get a set of XRef objects that originate at a given address region bounded by start and end. Useful for finding references from a basic block or function.

**Return type**
set[*XRef*]

**class** angr.knowledge_plugins.xrefs.**XRefType**

Bases: object

**Offset = 0**

**Read = 1**

**Write = 2**

**static to_string**(*ty*)

## Submodules

*xref*
*xref_manager*
*xref_types*

### angr.knowledge_plugins.xrefs.xref

**class** angr.knowledge_plugins.xrefs.xref.**XRef**

Bases: *Serializable*

XRef describes a reference to a MemoryData instance (if a MemoryData instance is available) or just an address.

**__init__**(*ins_addr=None*, *block_addr=None*, *stmt_idx=None*, *insn_op_idx=None*, *memory_data=None*, *dst=None*, *xref_type=None*)

**Parameters**

- **ins_addr** (*int | None*)
- **block_addr** (*int | None*)
- **stmt_idx** (*int | None*)
- **insn_op_idx** (*int | None*)
- **memory_data** (MemoryData | *None*)
- **dst** (*int | None*)

**ins_addr:** int | None

**insn_op_idx:** int | None

**block_addr:** int | None

**stmt_idx:** int | None

**memory_data**

**type**

**dst**

**property type_string**

**insn_op_type**

**copy**()

### angr.knowledge_plugins.xrefs.xref_manager

**class** angr.knowledge_plugins.xrefs.xref_manager.**XrefDict**

Bases: SortedDict

A SortedDict that maps addresses to sets of XRefs. It adds defaultdict-like behavior around SortedDict.

**get_xrefs_in_range**(*start*, *end*)

Get a set of XRef objects that point to addresses in the given range.

**class** angr.knowledge_plugins.xrefs.xref_manager.**XRefManager**

Bases: *KnowledgeBasePlugin*, *Serializable*

**__init__**(*kb*)

**copy**()

**clear**()

**add_xref**(*xref*)

**add_xrefs**(*xrefs*)

**get_xrefs_by_ins_addr**(*ins_addr*)

**get_xrefs_by_dst**(*dst*)

**get_xrefs_by_dst_region**(*start*, *end*)

Get a set of XRef objects that point to a given address region bounded by start and end. Will only return absolute xrefs, not relative ones (like SP offsets)

**get_next_xref_addr_by_dst**(*addr*)

Get the next XRef object whose address is greater than or equal to the given address. Will only return absolute xrefs, not relative ones (like SP offsets)

**Return type**
int | None

**Parameters**
**addr** (*int*)

**get_xrefs_by_ins_addr_region**(*start*, *end*)

Get a set of XRef objects that originate at a given address region bounded by start and end. Useful for finding references from a basic block or function.

**Return type**
set[*XRef*]

### angr.knowledge_plugins.xrefs.xref_types

**class** angr.knowledge_plugins.xrefs.xref_types.**XRefType**

Bases: object

**Offset = 0**

**Read = 1**

**Write = 2**

**static to_string**(*ty*)

## 10.25 angr.llm_client

**class** angr.llm_client.**AgentKind**

Bases: Enum

The kind of pydantic-ai Agent to retrieve from the LLMClient cache.

**STRING = 'string'**

**STRUCTURED = 'structured'**

**class** angr.llm_client.**LLMClient**

Bases: object

A client for interacting with LLMs via pydantic-ai. Used by the decompiler to suggest improved variable names, function names, and types.

**__init__**(*model*, *api_key=None*, *api_base=None*, *max_tokens=4096*, *temperature=0.0*)

**Parameters**

- **model** (*str*)
- **api_key** (*str | None*)
- **api_base** (*str | None*)
- **max_tokens** (*int*)
- **temperature** (*float*)

**infer_provider**(*provider*)

Infer the provider from the provider name.

**Return type**
Provider[Any]

**Parameters**
**provider** (*str*)

**classmethod from_env**()

Create an LLMClient from environment variables.

Uses ANGR_LLM_MODEL (required), ANGR_LLM_API_KEY (optional), and ANGR_LLM_API_BASE (optional). Returns None if ANGR_LLM_MODEL is not set.

**Return type**
*LLMClient* | None

**completion**(*messages*, ***kwargs*)

Call the LLM with the given messages and return the response text.

**Return type**
str

**Parameters**
**messages** (*list[dict[str, str]]*)

**completion_structured**[*T*](*messages*, *output_type*, *raise_exc=False*, ***kwargs*)

Call the LLM with the given messages and return a validated Pydantic model. Returns None if the call fails.

**Parameters**

- **raise_exc** (bool) – If True, exceptions are propagated to the caller instead of being caught.
- **messages** (*list[dict[str, str]]*)
- **output_type** (type*[T]*)

**Return type**
Optional[T]

**completion_json**(*messages*, *raise_exc=False*, ***kwargs*)

Call the LLM and parse the response as JSON. Strips markdown code fences if present. Returns None on parse failure. Kept for backwards compatibility; prefer completion_structured().

**Parameters**

- **raise_exc** (bool) – If True, exceptions are propagated to the caller instead of being caught.
- **messages** (*list[dict[str, str]]*)

**Return type**
dict | None

## 10.26 angr.llm_models

**class** angr.llm_models.**VariableRename**

Bases: BaseModel

**old_name:** str

**new_name:** str

**model_config:** ClassVar[ConfigDict] = {}

Configuration for the model, should be a dictionary conforming to [*ConfigDict*][pydantic.config.ConfigDict].

class angr.llm_models.**VariableNameSuggestions**

Bases: BaseModel

**renames:** list[*VariableRename*]

**model_config:** ClassVar[ConfigDict] = {}

Configuration for the model, should be a dictionary conforming to [*ConfigDict*][pydantic.config.ConfigDict].

class angr.llm_models.**FunctionNameSuggestion**

Bases: BaseModel

**function_name:** str

**model_config:** ClassVar[ConfigDict] = {}

Configuration for the model, should be a dictionary conforming to [*ConfigDict*][pydantic.config.ConfigDict].

class angr.llm_models.**VariableTypeChange**

Bases: BaseModel

**variable_name:** str

**new_type:** str

**model_config:** ClassVar[ConfigDict] = {}

Configuration for the model, should be a dictionary conforming to [*ConfigDict*][pydantic.config.ConfigDict].

class angr.llm_models.**VariableTypeSuggestions**

Bases: BaseModel

**type_changes:** list[*VariableTypeChange*]

**model_config:** ClassVar[ConfigDict] = {}

Configuration for the model, should be a dictionary conforming to [*ConfigDict*][pydantic.config.ConfigDict].

## 10.27 angr.mcp

angr MCP Server - Model Context Protocol interface for angr binary analysis.

This module provides an MCP server that exposes angr's binary analysis capabilities through standardized tools accessible by LLM applications.

**Usage:**

# Run as module with stdio transport (for Claude Desktop, etc.) python -m angr.mcp

# Run with SSE transport python -m angr.mcp –transport sse –port 8080

# Run with HTTP transport python -m angr.mcp –transport http –host 0.0.0.0 –port 8080 –path /mcp

# Programmatic usage from angr.mcp import create_server server = create_server() server.run()

**Available Tools:**

- load_binary: Load a binary file for analysis
- get_cfg: Build the control flow graph
- recover_calling_conventions: Recover calling conventions and prototypes
- list_functions: List discovered functions
- get_function_info: Get detailed function information
- decompile_function: Decompile to pseudocode
- get_xrefs: Get cross-references
- get_strings: Extract strings from binary
- get_imports: List imported symbols
- get_exports: List exported symbols
- get_basic_blocks: Get basic blocks with disassembly
- get_callgraph: Get function call graph
- find_functions_by_pattern: Search functions by name
- list_projects: List active analysis sessions
- close_project: Close a project session

**Editing Tools (batch; see angr.mcp.edit_tools):**

- rename: Rename functions, decompilation variables, and globals
- set_type: Set variable types, globals, return types, and function prototypes
- set_comments: Set or clear comments at addresses

**exception** angr.mcp.**CFGNotBuiltError**

Bases: *MCPAngrError*

Raised when CFG is required but not built.

**exception** angr.mcp.**DecompilationError**

Bases: *MCPAngrError*

Raised when decompilation fails.

**exception** angr.mcp.**FunctionNotFoundError**

Bases: *MCPAngrError*

Raised when a function cannot be found.

**exception** angr.mcp.**MCPAngrError**

Bases: *AngrError*, ToolError

Base exception for MCP angr server errors.

Also a fastmcp ToolError: FastMCP masks the message of anything else, so a client would otherwise see a generic failure instead of the reason.

**exception** angr.mcp.**ProjectNotFoundError**

Bases: *MCPAngrError*

Raised when a project ID is not found.

**class** angr.mcp.**ProjectSession**

Bases: object

Represents a loaded angr project with its associated analyses.

**project_id:** str

**project:** *Project*

**binary_path:** str

**cfg:** *CFGModel* | None = None

**sha256:** str = ''

**flavor:** str = 'pseudocode'

**lock:** RLock

**set_flavor**(*flavor*)

Set the project-wide decompilation flavor and return the previous one.

**Return type**
str

**Parameters**
**flavor** (*str*)

**property has_cfg:** bool

Check if CFG has been built for this project.

**exclusive**()

Serialize access to this project.

FastMCP runs synchronous tools on worker threads, so two calls can reach the same Project and KnowledgeBase at once. Neither is thread-safe, and the decompilation and variable caches spill to LMDB, where a concurrent eviction and reload can hand back a half-imported object. Read-only tools are not exempt: a read racing an eviction is exactly that hazard.

**Return type**
Iterator[*ProjectSession*]

**__init__**(*project_id*, *project*, *binary_path*, *cfg=None*, *sha256=''*, *flavor=Flavors.DEFAULT_FLAVOR*, *lock=<factory>*)

**Parameters**

- **project_id** (*str*)
- **project** (*angr.Project*)
- **binary_path** (*str*)
- **cfg** (CFGModel | *None*)
- **sha256** (*str*)
- **flavor** (*str*)

- **lock** (*threading.RLock*)

**Return type**
None

**class** angr.mcp.**SessionManager**

Bases: object

Manages multiple angr project sessions.

This class maintains state across MCP tool invocations, allowing projects to persist between calls.

**__init__**()

**Return type**
None

**create_session**(*binary_path*, ***kwargs*)

Load a binary and create a new project session.

**Parameters**

- **binary_path** (str) – Path to the binary to analyze
- **kwargs** (Any) – Additional arguments passed to angr.Project

**Return type**
*ProjectSession*

**Returns**
The created ProjectSession with unique ID

**get_session**(*project_id*)

Get an existing session by ID.

**Parameters**
**project_id** (str) – The project ID to look up

**Return type**
*ProjectSession*

**Returns**
The ProjectSession

**Raises**
**KeyError** – If no project with that ID exists

**list_sessions**()

List all active sessions.

**Return type**
list[dict[str, Any]]

**Returns**
List of session metadata dictionaries

**close_session**(*project_id*)

Close and remove a session.

**Parameters**
**project_id** (str) – The project ID to close

**Return type**
bool

**Returns**
True if closed, False if not found

angr.mcp.**create_server**()

Create and return the configured MCP server instance.

**Return type**
FastMCP

angr.mcp.**get_session_manager**()

Get or create the global session manager.

**Return type**
*SessionManager*

### Submodules

| | |
|---|---|
| *edit_tools* | Batch edit tools: rename, set_type, and set_comments. |
| *errors* | |
| *serializers* | |
| *server* | Main MCP server for angr binary analysis. |
| *session* | Session management for angr MCP server. |

## 10.27.1 angr.mcp.edit_tools

Batch edit tools: rename, set_type, and set_comments.

Every tool takes a list of items and returns one result per item. Per-item failures are reported as data rather than raised, so one bad item does not discard the work done by its siblings – that is the point of batching. Only whole-call problems (an unknown project, a malformed request) raise.

angr.mcp.edit_tools.**rename**(*project_id*, *items*, *dry_run=False*, *stop_on_error=False*, *allow_overwrite=False*, *auto_decompile=True*)

Rename functions, decompilation variables, and globals in one call.

Each item needs a "kind" and a "new_name":

- kind "function": identify it with "name" or "address".
- kind "variable": "function" (name or address) plus "name", the variable's current name as it appears in the pseudocode. Covers locals, arguments, and stack slots – angr routes them through one path, so the item does not say which; the result reports the resolved storage.
- kind "global": "address", or "name" if the global already has a label.

Renames persist across re-decompilation. Renaming a variable requires the function to have been decompiled; with auto_decompile it is decompiled on demand.

**Parameters**

- **project_id** (str) – The project ID
- **items** (list[dict[str, Any]]) – The rename requests
- **dry_run** (bool) – Resolve and validate without changing anything. Not side-effect free: resolving a variable name may decompile the function.
- **stop_on_error** (bool) – Stop at the first failure and mark the rest skipped. Edits already applied are NOT rolled back; use dry_run as a pre-flight.

- **allow_overwrite** (bool) – Permit a name already bound to something else (default: False)
- **auto_decompile** (bool) – Decompile a function on demand when a variable rename needs it

**Return type**
dict[str, Any]

**Returns**
A per-item result list plus counts of succeeded/unchanged/failed/skipped

angr.mcp.edit_tools.**set_type**(*project_id*, *items*, *dry_run=False*, *stop_on_error=False*, *redecompile=False*, *auto_decompile=True*)

Set types on decompilation variables, globals, and function prototypes in one call.

Each item needs a "kind" and a "type":

- kind "variable": "function" plus "name". Retyping an argument rewrites the function's prototype, which forces that function to be re-decompiled.
- kind "function": identify it with "function", "name", or "address"; "type" is a full signature, e.g. `int parse(char *buf, int len)`. The name inside the signature is ignored – use rename for that. This discards the function's cached decompilation and variables; earlier renames and manual types, including ones set by earlier items in the same batch, are restored afterwards.
- kind "return": same identifiers, replaces only the return type and keeps the arguments.
- kind "global": "address" or "name", plus "type".

Types are re-inferred through the cached constraints once per affected function rather than per item. That reflow does NOT rebuild the syntax tree, so a retype that should change how an access renders – a struct field, an array index – needs redecompile=True.

**Parameters**

- **project_id** (str) – The project ID
- **items** (list[dict[str, Any]]) – The type requests
- **dry_run** (bool) – Validate and resolve without changing anything
- **stop_on_error** (bool) – Stop at the first failure; already-applied edits are NOT rolled back
- **redecompile** (bool) – Fully re-decompile each affected function instead of reflowing types
- **auto_decompile** (bool) – Decompile a function on demand when an item needs it

**Return type**
dict[str, Any]

**Returns**
A per-item result list plus counts of succeeded/unchanged/failed/skipped

angr.mcp.edit_tools.**set_comments**(*project_id*, *items*, *dry_run=False*, *stop_on_error=False*)

Set or clear comments at addresses in one call.

Each item needs a "kind" and a "comment"; an empty comment clears it.

- kind "address": "address" is any address in the binary.
- kind "function": identify it with "function", "name", or "address"; comments its header.

A comment is written to the knowledge base – where the disassembly and the function header read it – and mirrored next to the matching pseudocode statement. Because pseudocode comments are keyed by instruction address, an address that is not a statement boundary is snapped down to the nearest one; each result reports "snapped_from" and whether the comment actually rendered inline ("rendered_inline") rather than in the orphaned-comments block.

**Parameters**

- **project_id** (str) – The project ID
- **items** (list[dict[str, Any]]) – The comment requests
- **dry_run** (bool) – Resolve addresses without changing anything
- **stop_on_error** (bool) – Stop at the first failure; already-applied edits are NOT rolled back

**Return type**
dict[str, Any]

**Returns**
A per-item result list plus counts of succeeded/unchanged/failed/skipped

### 10.27.2 angr.mcp.errors

**exception** angr.mcp.errors.**MCPAngrError**

Bases: *AngrError*, ToolError

Base exception for MCP angr server errors.

Also a fastmcp ToolError: FastMCP masks the message of anything else, so a client would otherwise see a generic failure instead of the reason.

**exception** angr.mcp.errors.**ProjectNotFoundError**

Bases: *MCPAngrError*

Raised when a project ID is not found.

**exception** angr.mcp.errors.**CFGNotBuiltError**

Bases: *MCPAngrError*

Raised when CFG is required but not built.

**exception** angr.mcp.errors.**FunctionNotFoundError**

Bases: *MCPAngrError*

Raised when a function cannot be found.

**exception** angr.mcp.errors.**DecompilationError**

Bases: *MCPAngrError*

Raised when decompilation fails.

**exception** angr.mcp.errors.**DecompilationComplexityError**

Bases: *DecompilationError*

Raised when a function is too large for the decompiler's complexity limits.

The message names the limit and the measured size so the caller can decide whether to raise the limit or skip the function.

**exception** angr.mcp.errors.**InvalidArgumentError**

Bases: *MCPAngrError*, ValueError

Raised when a tool is called with unusable arguments.

### 10.27.3 angr.mcp.serializers

angr.mcp.serializers.**serialize_function**(*func*, *include_blocks=False*)

Serialize a Function object to a JSON-compatible dict.

**Parameters**

- **func** (*Function*) – The angr Function to serialize
- **include_blocks** (bool) – Whether to include block addresses

**Return type**
dict[str, Any]

**Returns**
Dictionary with function information

angr.mcp.serializers.**serialize_function_summary**(*func*)

Serialize minimal function info for list views.

**Parameters**
**func** (*Function*) – The angr Function to serialize

**Return type**
dict[str, Any]

**Returns**
Dictionary with minimal function information

angr.mcp.serializers.**serialize_xref**(*xref*)

Serialize an XRef object.

**Parameters**
**xref** (*XRef*) – The angr XRef to serialize

**Return type**
dict[str, Any]

**Returns**
Dictionary with cross-reference information

angr.mcp.serializers.**serialize_basic_block**(*block*, *include_disasm=True*)

Serialize a basic block.

**Parameters**

- **block** (Any) – The angr Block to serialize
- **include_disasm** (bool) – Whether to include disassembly

**Return type**
dict[str, Any]

**Returns**
Dictionary with block information

angr.mcp.serializers.**serialize_cfg_stats**(*cfg_model*)

Serialize CFG statistics.

**Parameters**
**cfg_model** (*CFGModel*) – The angr CFGModel to summarize

**Return type**
dict[str, Any]

**Returns**
Dictionary with CFG statistics

angr.mcp.serializers.**serialize_symbol**(*symbol*)

Serialize a CLE symbol.

**Parameters**
**symbol** (Any) – The CLE Symbol to serialize

**Return type**
dict[str, Any]

**Returns**
Dictionary with symbol information

### 10.27.4 angr.mcp.server

Main MCP server for angr binary analysis.

**class** angr.mcp.server.**StdoutGuardMiddleware**

Bases: Middleware

Keep analysis output off of stdout.

Under the stdio transport, stdout is the JSON-RPC channel. This middleware redirects stdout to stderr to avoid messing with the stdio transport.

**async on_message**(*context*, *call_next*)

**Return type**
Any

**Parameters**

- **context** (*MiddlewareContext[Any]*)
- **call_next** (*CallNext[Any, Any]*)

angr.mcp.server.**load_binary**(*binary_path*, *auto_load_libs=False*, *arch=None*, *backend=None*, *base_address=None*, *entry_point=None*)

Load a binary file as an angr Project for analysis.

This is typically the first tool to call. It creates a new analysis session and returns a project_id that must be used for subsequent operations.

Headered ELF, PE, and Mach-O files need no loader options. A universal (fat) Mach-O loads every supported slice unless arch selects one. A headerless raw image needs backend "blob" plus arch, and usually base_address and entry_point. 16-bit DOS executables are not supported.

**Parameters**

- **binary_path** (str) – Absolute path to the binary file to analyze
- **auto_load_libs** (bool) – Whether to automatically load shared libraries (default: False)
- **arch** (str | None) – Architecture identifier (e.g. "x86_64", "aarch64", "armel", "mips32"). Selects the matching slice of a universal Mach-O, or overrides the architecture of a headered file.
- **backend** (str | None) – Loader backend override; "blob" loads a headerless raw image (requires arch)
- **base_address** (str | None) – Load address for a raw image, as a hex string (e.g. "0x8000000")

- **entry_point** (str | None) – Entry point for a raw image, as a hex string

**Return type**
dict[str, Any]

**Returns**
Project information including project_id, the file's SHA-256, architecture, entry point, and, for a universal Mach-O, the architectures its container offers

angr.mcp.server.**get_cfg**(*project_id*, *normalize=True*, *data_references=True*)

Build or retrieve the Control Flow Graph (CFG) for a project.

The CFG is required for most analysis operations including function discovery, decompilation, and cross-reference analysis.

**Parameters**

- **project_id** (str) – The project ID returned by load_binary
- **normalize** (bool) – Whether to normalize the CFG (recommended: True)
- **data_references** (bool) – Whether to collect data references (for string analysis)

**Return type**
dict[str, Any]

**Returns**
CFG statistics including node/edge counts and functions discovered

angr.mcp.server.**recover_calling_conventions**(*project_id*, *workers=0*, *force=False*)

Recover calling conventions and prototypes for every function in the binary.

Requires CFG to be built first via get_cfg. This improves the quality of decompilation output, especially the arguments shown at call sites.

**Parameters**

- **project_id** (str) – The project ID
- **workers** (int) – Number of worker processes to use (0 = run in-process, the default)
- **force** (bool) – Re-analyze functions that already have a calling convention or prototype

**Return type**
dict[str, Any]

**Returns**
Number of functions for which a calling convention was recovered

angr.mcp.server.**list_functions**(*project_id*, *filter_plt=None*, *filter_syscall=None*, *name_pattern=None*, *limit=100*, *offset=0*)

List all functions discovered in the binary.

Requires CFG to be built first via get_cfg.

**Parameters**

- **project_id** (str) – The project ID
- **filter_plt** (bool | None) – If True, only show PLT stubs; if False, exclude them
- **filter_syscall** (bool | None) – If True, only show syscalls; if False, exclude them
- **name_pattern** (str | None) – Filter functions by name substring (case-insensitive)
- **limit** (int) – Maximum number of functions to return (default: 100)

- **offset** (int) – Number of functions to skip (for pagination)

**Return type**
dict[str, Any]

**Returns**
List of function summaries with addresses and names

angr.mcp.server.**get_function_info**(*project_id*, *address=None*, *name=None*, *include_blocks=False*)

Get detailed information about a specific function.

Specify either address (hex string like "0x401000") or function name.

**Parameters**

- **project_id** (str) – The project ID
- **address** (str | None) – Function address as hex string (e.g., "0x401000")
- **name** (str | None) – Function name to look up
- **include_blocks** (bool) – Whether to include list of basic block addresses

**Return type**
dict[str, Any]

**Returns**
Detailed function information including size, complexity, etc. "num_blocks" against "decompilation_block_limit" tells you up front whether decompile_function will refuse this function as too complex.

angr.mcp.server.**get_decompilation_flavor**(*project_id*)

Report the project-wide decompilation flavor and the language angr detected in the binary.

The flavor selects how decompile_function renders code: "pseudocode" (C-like, the default), "rust", or "go". Decompilation caches, prototypes, and edits are kept per flavor. The detected language is a hint for choosing a flavor; it does not change the setting.

**Parameters**
**project_id** (str) – The project ID

**Return type**
dict[str, Any]

**Returns**
The current flavor, the valid flavors, and the language detection result

angr.mcp.server.**set_decompilation_flavor**(*project_id*, *flavor*)

Set the project-wide decompilation flavor used by decompile_function and the edit tools.

**Parameters**

- **project_id** (str) – The project ID
- **flavor** (str) – "pseudocode", "rust", or "go"

**Return type**
dict[str, Any]

**Returns**
The previous and current flavor

angr.mcp.server.**decompile_function**(*project_id*, *address=None*, *name=None*, *max_function_blocks=None*, *max_ail_statements=None*, *flavor=None*)

Decompile a function to C-like pseudocode, or to Rust- or Go-flavored code.

Specify either address (hex string) or function name.

Pathologically large functions (e.g. packer filler that linear disassembly turns into thousands of blocks) can keep the decompiler busy indefinitely, so two size limits are checked before the expensive work starts. Exceeding either one fails with an error naming the limit and the measured size, so you can retry with a larger limit or move on to another function.

**Parameters**

- **project_id** (str) – The project ID
- **address** (str | None) – Function address as hex string (e.g., "0x401000")
- **name** (str | None) – Function name to decompile
- **max_function_blocks** (int | None) – Refuse to decompile a function whose CFG has more basic blocks than this (default: 50000; 0 disables the check). get_function_info reports a function's block count as "num_blocks" and this default as "decompilation_block_limit".
- **max_ail_statements** (int | None) – Refuse to decompile a function whose AIL graph has more statements than this (default: 1000000; 0 disables the check)
- **flavor** (str | None) – Decompilation flavor for this call only: "pseudocode", "rust", or "go". Defaults to the project-wide flavor (see get_decompilation_flavor / set_decompilation_flavor).

**Return type**
dict[str, Any]

**Returns**
Decompiled code, the flavor it was rendered in, and function metadata

angr.mcp.server.**get_xrefs**(*project_id*, *address*, *direction='to'*)

Get cross-references to or from a specific address.

**Parameters**

- **project_id** (str) – The project ID
- **address** (str) – The address to query (hex string, e.g., "0x401000")
- **direction** (str) – "to" for references TO this address, "from" for references FROM this address

**Return type**
dict[str, Any]

**Returns**
List of cross-references with source/destination and type

angr.mcp.server.**get_strings**(*project_id*, *min_length=4*, *limit=100*)

Extract strings from the binary.

Requires CFG with data_references=True.

**Parameters**

- **project_id** (str) – The project ID
- **min_length** (int) – Minimum string length to include (default: 4)

- **limit** (int) – Maximum number of strings to return (default: 100)

**Return type**
dict[str, Any]

**Returns**
List of strings with their addresses

angr.mcp.server.**get_imports**(*project_id*)

List imported symbols (external functions/variables the binary depends on).

**Parameters**
**project_id** (str) – The project ID

**Return type**
dict[str, Any]

**Returns**
List of imported symbols with their names and addresses

angr.mcp.server.**get_exports**(*project_id*)

List exported symbols (functions/variables this binary provides).

**Parameters**
**project_id** (str) – The project ID

**Return type**
dict[str, Any]

**Returns**
List of exported symbols with their names and addresses

angr.mcp.server.**get_basic_blocks**(*project_id*, *function_address*, *include_disasm=True*)

Get all basic blocks for a function.

**Parameters**

- **project_id** (str) – The project ID
- **function_address** (str) – Function address as hex string
- **include_disasm** (bool) – Whether to include disassembly for each block

**Return type**
dict[str, Any]

**Returns**
List of basic blocks with their instructions

angr.mcp.server.**get_callgraph**(*project_id*, *max_depth=None*, *root_address=None*)

Get the function call graph.

**Parameters**

- **project_id** (str) – The project ID
- **max_depth** (int | None) – Maximum depth from root (None for full graph)
- **root_address** (str | None) – Optional starting function address for subgraph

**Return type**
dict[str, Any]

**Returns**
Call graph as nodes and edges

angr.mcp.server.**find_functions_by_pattern**(*project_id*, *pattern*, *search_type='contains'*)

Search for functions by name pattern.

**Parameters**

- **project_id** (str) – The project ID
- **pattern** (str) – Search pattern (depends on search_type)
- **search_type** (str) – "contains", "startswith", "endswith", or "regex"

**Return type**
dict[str, Any]

**Returns**
List of matching functions

angr.mcp.server.**list_projects**()

List all currently loaded projects/sessions.

**Return type**
dict[str, Any]

**Returns**
List of active project sessions with their IDs and metadata

angr.mcp.server.**close_project**(*project_id*)

Close a project and free its resources.

**Parameters**
**project_id** (str) – The project ID to close

**Return type**
dict[str, Any]

**Returns**
Confirmation of closure

angr.mcp.server.**create_server**()

Create and return the configured MCP server instance.

**Return type**
FastMCP

### 10.27.5 angr.mcp.session

Session management for angr MCP server.

angr.mcp.session.**parse_flavor**(*flavor*)

Validate a decompilation flavor name, naming the valid ones on failure.

**Return type**
str

**Parameters**
**flavor** (*str*)

angr.mcp.session.**parse_address_option**(*name*, *value*)

Parse an optional hex-or-decimal address option, naming the option on failure.

**Return type**
int | None

**Parameters**

- **name** (*str*)
- **value** (*str | int | None*)

angr.mcp.session.**parse_arch_option**(*arch*)

Resolve an archinfo identifier such as “x86_64”, “aarch64”, “armel”, or “mips32”.

**Return type**
Arch | None

**Parameters**
**arch** (*str | None*)

angr.mcp.session.**build_main_opts**(*, *arch=None*, *backend=None*, *base_address=None*, *entry_point=None*)

Translate load_binary’s optional loader inputs into CLE main_opts.

`arch` selects the slice of a universal Mach-O or overrides a headered file. `backend="blob"` with `arch` loads a headerless raw binary at `base_address` with `entry_point`.

**Return type**
dict[str, Any]

**Parameters**

- **arch** (*str | None*)
- **backend** (*str | None*)
- **base_address** (*str | int | None*)
- **entry_point** (*str | int | None*)

angr.mcp.session.**reject_dos_executable**(*path*)

16-bit DOS MZ images share PE’s magic but have no lifter; report that instead of a loader crash.

**Return type**
None

**Parameters**
**path** (*Path*)

**class** angr.mcp.session.**ProjectSession**

Bases: object

Represents a loaded angr project with its associated analyses.

**project_id:** str

**project:** *Project*

**binary_path:** str

**cfg:** *CFGModel* | None = None

**sha256:** str = ''

**flavor:** str = 'pseudocode'

**lock:** RLock

**set_flavor**(*flavor*)

Set the project-wide decompilation flavor and return the previous one.

**Return type**
str

**Parameters**
**flavor** (*str*)

**property has_cfg: bool**

Check if CFG has been built for this project.

**exclusive**()

Serialize access to this project.

FastMCP runs synchronous tools on worker threads, so two calls can reach the same Project and KnowledgeBase at once. Neither is thread-safe, and the decompilation and variable caches spill to LMDB, where a concurrent eviction and reload can hand back a half-imported object. Read-only tools are not exempt: a read racing an eviction is exactly that hazard.

**Return type**
Iterator[*ProjectSession*]

**__init__**(*project_id*, *project*, *binary_path*, *cfg=None*, *sha256=''*, *flavor=Flavors.DEFAULT_FLAVOR*, *lock=<factory>*)

**Parameters**

- **project_id** (*str*)
- **project** (*angr.Project*)
- **binary_path** (*str*)
- **cfg** (CFGModel | *None*)
- **sha256** (*str*)
- **flavor** (*str*)
- **lock** (*threading.RLock*)

**Return type**
None

**class** angr.mcp.session.**SessionManager**

Bases: object

Manages multiple angr project sessions.

This class maintains state across MCP tool invocations, allowing projects to persist between calls.

**__init__**()

**Return type**
None

**create_session**(*binary_path*, ***kwargs*)

Load a binary and create a new project session.

**Parameters**

- **binary_path** (str) – Path to the binary to analyze
- **kwargs** (Any) – Additional arguments passed to angr.Project

**Return type**
*ProjectSession*

**Returns**
The created ProjectSession with unique ID

**get_session**(*project_id*)

Get an existing session by ID.

**Parameters**
**project_id** (str) – The project ID to look up

**Return type**
*ProjectSession*

**Returns**
The ProjectSession

**Raises**
**KeyError** – If no project with that ID exists

**list_sessions**()

List all active sessions.

**Return type**
list[dict[str, Any]]

**Returns**
List of session metadata dictionaries

**close_session**(*project_id*)

Close and remove a session.

**Parameters**
**project_id** (str) – The project ID to close

**Return type**
bool

**Returns**
True if closed, False if not found

angr.mcp.session.**get_session_manager**()

Get or create the global session manager.

**Return type**
*SessionManager*

## 10.28 angr.misc

**class** angr.misc.**HookSet**

Bases: object

A HookSet is a static class that provides the capability to apply many hooks to an object.

**static install_hooks**(*target*, ***hooks*)

Given the target *target*, apply the hooks given as keyword arguments to it. If any targeted method has already been hooked, the hooks will not be overridden but will instead be pushed into a list of pending hooks. The final behavior should be that all hooks call each other in a nested stack.

**Parameters**

- **target** – Any object. Its methods named as keys in *hooks* will be replaced by *HookedMethod* objects.
- **hooks** – Any keywords will be interpreted as hooks to apply. Each method named will hooked with the corresponding function value.

**static remove_hooks**(*target*, ***hooks*)

Remove the given hooks from the given target.

**Parameters**

- **target** – The object from which to remove hooks. If all hooks are removed from a given method, the HookedMethod object will be removed and replaced with the original function.
- **hooks** – Any keywords will be interpreted as hooks to remove. You must provide the exact hook that was applied so that it can it can be identified for removal among any other hooks.

**static copy_hooks**(*source*, *target*, *domain*)

Copy the hooks from source onto target.

If the current callstack includes hooked methods from source, the already-called methods will not be included in the copy.

domain is a list of names that might be hooked.

**class** angr.misc.**Loggers**

Bases: object

Implements a loggers manager for angr.

**__init__**(*default_level=30*)

**default_level**

**profiling_enabled**

**handler**

**IN_SCOPE = ('angr', 'claripy', 'cle', 'pyvex', 'archinfo', 'tracer', 'driller', 'rex', 'patcherex', 'identifier')**

**load_all_loggers**()

A dumb and simple way to conveniently aggregate all loggers.

Adds attributes to this instance of each registered logger, replacing '.' with '_'

**enable_root_logger**()

Enable angr's default logger

**disable_root_logger**()

Disable angr's default logger

**static setall**(*level*)

**class** angr.misc.**PicklableLock**

Bases: object

Normal thread-locks are not pickleable. This provides a pickleable lock by mandating that the lock is unlocked during serialization.

**__init__**(**args*, ***kwargs*)

**acquire**(**args*, ***kwargs*)

**locked**()

**release**()

**class** angr.misc.**PluginHub**

Bases: Generic[P]

A plugin hub is an object which contains many plugins, as well as the notion of a "preset", or a backer that can provide default implementations of plugins which cater to a certain circumstance.

Objects in angr like the SimState, the Analyses hub, the SimEngine selector, etc all use this model to unify their mechanisms for automatically collecting and selecting components to use. If you're familiar with design patterns this is a configurable Strategy Pattern.

Each PluginHub subclass should have a corresponding Plugin subclass, and perhaps a PluginPreset subclass if it wants its presets to be able to specify anything more interesting than a list of defaults.

**__init__**()

**Return type**
None

**classmethod register_default**(*name*, *plugin_cls*, *preset='default'*)

**Return type**
None

**Parameters**

- **name** (*str*)
- **plugin_cls** (type)
- **preset** (*str*)

**classmethod register_preset**(*name*, *preset*)

Register a preset instance with the class of the hub it corresponds to. This allows individual plugin objects to automatically register themselves with a preset by using a classmethod of their own with only the name of the preset to register with.

**Return type**
None

**Parameters**

- **name** (*str*)
- **preset** (PluginPreset*[P]*)

**property plugin_preset: Optional[*PluginPreset*[P]]**

Get the current active plugin preset

**property has_plugin_preset: bool**

Check whether or not there is a plugin preset in use on this hub right now

**use_plugin_preset**(*preset*)

Apply a preset to the hub. If there was a previously active preset, discard it.

Preset can be either the string name of a preset or a PluginPreset instance.

**Return type**
None

**Parameters**
**preset** (*str | PluginPreset[P]*)

`discard_plugin_preset`()

Discard the current active preset. Will release any active plugins that could have come from the old preset.

**Return type**
None

`get_plugin`(*name*)

Get the plugin named `name`. If no such plugin is currently active, try to activate a new one using the current preset.

**Return type**
P

**Parameters**
**name** (*str*)

`has_plugin`(*name*)

Return whether or not a plugin with the name `name` is currently active.

**Return type**
bool

**Parameters**
**name** (*str*)

`register_plugin`(*name*, *plugin*)

Add a new plugin `plugin` with name `name` to the active plugins.

**Return type**
P

**Parameters**

- **name** (*str*)
- **plugin** (*P*)

`release_plugin`(*name*)

Deactivate and remove the plugin with name `name`.

**Return type**
None

**Parameters**
**name** (*str*)

`class angr.misc.PluginPreset`

Bases: Generic[P]

A plugin preset object contains a mapping from name to a plugin class. A preset can be active on a hub, which will cause it to handle requests for plugins which are not already present on the hub.

Unlike Plugins and PluginHubs, instances of PluginPresets are defined on the module level for individual presets. You should register the preset instance with a hub to allow plugins to easily add themselves to the preset without an explicit reference to the preset itself.

`__init__`()

**Return type**
None

`activate`(*hub*)

This method is called when the preset becomes active on a hub.

**Return type**
None

**Parameters**
**hub** (PluginHub[P])

`deactivate`(*hub*)

This method is called when the preset is discarded from the hub.

**Return type**
None

**Parameters**
**hub** (PluginHub[P])

`add_default_plugin`(*name*, *plugin_cls*)

Add a plugin to the preset.

**Return type**
None

**Parameters**

- **name** (*str*)
- **plugin_cls** (type[P])

`list_default_plugins`()

Return a list of the names of available default plugins.

**Return type**
list[str]

`request_plugin`(*name*)

Return the plugin class which is registered under the name `name`, or raise NoPlugin if the name isn't available.

**Return type**
type[P]

**Parameters**
**name** (*str*)

`copy`()

Return a copy of self.

**Return type**
*PluginPreset*[P]

### 10.28.1 angr.misc.ansi

**class** angr.misc.ansi.**Color**

Bases: Enum

The basic ansi colors

**black = 30**

**red = 31**

**green = 32**

**yellow = 33**

**blue = 34**

**magenta = 35**

**cyan = 36**

**white = 37**

**class** angr.misc.ansi.**BackgroundColor**

Bases: Enum

**black = 40**

**red = 41**

**green = 42**

**yellow = 43**

**blue = 44**

**magenta = 45**

**cyan = 46**

**white = 47**

angr.misc.ansi.**color**(*c*, *bright*)

Return the ansi prefix using the given code Bright may not be used with a BackgroundColor

**Parameters**

- **c** (Color | BackgroundColor)
- **bright** (*bool*)

### 10.28.2 angr.misc.autoimport

angr.misc.autoimport.**auto_import_packages**(*base_module*, *base_path*, *ignore_dirs=()*, *ignore_files=()*, *scan_modules=True*)

angr.misc.autoimport.**auto_import_modules**(*base_module*, *base_path*, *ignore_files=()*, *filter_func=None*)

**Parameters**
**filter_func** (*Callable | None*)

angr.misc.autoimport.**filter_module**(*mod*, *type_req=None*, *subclass_req=None*)

angr.misc.autoimport.**auto_import_source_files**(*base_path*, *ignore_files=()*, *filter_func=None*)

**Parameters**
**filter_func** (*Callable | None*)

### 10.28.3 angr.misc.bug_report

angr.misc.bug_report.**get_venv**()

angr.misc.bug_report.**print_versions**()

angr.misc.bug_report.**print_git_info**(*dirname*)

angr.misc.bug_report.**print_system_info**()

angr.misc.bug_report.**print_native_info**()

angr.misc.bug_report.**bug_report**()

### 10.28.4 angr.misc.hookset

These classes perform some python magic that we use to implement the nesting of exploration technique methods. This process is formalized as a "hooking" of a python method - each exploration technique's methods "hooks" a method of the same name on the simulation manager class.

**class** angr.misc.hookset.**HookSet**

Bases: object

A HookSet is a static class that provides the capability to apply many hooks to an object.

**static install_hooks**(*target*, ***hooks*)

Given the target *target*, apply the hooks given as keyword arguments to it. If any targeted method has already been hooked, the hooks will not be overridden but will instead be pushed into a list of pending hooks. The final behavior should be that all hooks call each other in a nested stack.

**Parameters**

- **target** – Any object. Its methods named as keys in *hooks* will be replaced by *HookedMethod* objects.
- **hooks** – Any keywords will be interpreted as hooks to apply. Each method named will hooked with the corresponding function value.

**static remove_hooks**(*target*, ***hooks*)

Remove the given hooks from the given target.

**Parameters**

- **target** – The object from which to remove hooks. If all hooks are removed from a given method, the HookedMethod object will be removed and replaced with the original function.
- **hooks** – Any keywords will be interpreted as hooks to remove. You must provide the exact hook that was applied so that it can it can be identified for removal among any other hooks.

**static copy_hooks**(*source*, *target*, *domain*)

Copy the hooks from source onto target.

If the current callstack includes hooked methods from source, the already-called methods will not be included in the copy.

domain is a list of names that might be hooked.

**class** angr.misc.hookset.**HookedMethod**

Bases: object

HookedMethod is a callable object which provides a stack of nested hooks.

**Parameters**
**func** – The bottom-most function which provides the original functionality that is being hooked

**Variables**

- **func** – Same as the eponymous parameter
- **pending** – The stack of hooks that have yet to be called. When this object is called, it will pop the last function in this list and call it. The function should call this object again in order to request the functionality of the original method, at which point the pop-dispatch mechanism will run recursively until the stack is exhausted, at which point the original function will be called. When the call returns, the hook will be restored to the stack.

**__init__**(*func*)

**copy_to**(*new_func*)

### 10.28.5 angr.misc.loggers

**class** angr.misc.loggers.**Loggers**

Bases: object

Implements a loggers manager for angr.

**__init__**(*default_level=30*)

**default_level**

**profiling_enabled**

**handler**

**IN_SCOPE = ('angr', 'claripy', 'cle', 'pyvex', 'archinfo', 'tracer', 'driller', 'rex', 'patcherex', 'identifier')**

**load_all_loggers**()

A dumb and simple way to conveniently aggregate all loggers.

Adds attributes to this instance of each registered logger, replacing '.' with '_'

**enable_root_logger**()

Enable angr's default logger

**disable_root_logger**()

Disable angr's default logger

**static setall**(*level*)

**class** angr.misc.loggers.**CuteFormatter**

Bases: Formatter

A log formatter that can print log messages with colors.

angr.misc.loggers.**is_enabled_for**(*logger*, *level*)

### 10.28.6 angr.misc.picklable_lock

**class** angr.misc.picklable_lock.**PicklableLock**

Bases: object

Normal thread-locks are not pickleable. This provides a pickleable lock by mandating that the lock is unlocked during serialization.

**__init__**(**args*, ***kwargs*)

**acquire**(**args*, ***kwargs*)

**locked**()

**release**()

**class** angr.misc.picklable_lock.**PicklableRLock**

Bases: *PicklableLock*

Same as above, but uses RLock instead of Lock for locking. Note that RLock does not provide an interface to tell whether is it presently held by any thread, and thus this class will lie about whether it is locked.

**locked**()

### 10.28.7 angr.misc.plugins

**class** angr.misc.plugins.**PluginHub**

Bases: Generic[P]

A plugin hub is an object which contains many plugins, as well as the notion of a "preset", or a backer that can provide default implementations of plugins which cater to a certain circumstance.

Objects in angr like the SimState, the Analyses hub, the SimEngine selector, etc all use this model to unify their mechanisms for automatically collecting and selecting components to use. If you're familiar with design patterns this is a configurable Strategy Pattern.

Each PluginHub subclass should have a corresponding Plugin subclass, and perhaps a PluginPreset subclass if it wants its presets to be able to specify anything more interesting than a list of defaults.

**__init__**()

**Return type**
None

**classmethod register_default**(*name*, *plugin_cls*, *preset='default'*)

**Return type**
None

**Parameters**

- **name** (*str*)
- **plugin_cls** (*type*)
- **preset** (*str*)

**classmethod register_preset**(*name*, *preset*)

Register a preset instance with the class of the hub it corresponds to. This allows individual plugin objects to automatically register themselves with a preset by using a classmethod of their own with only the name of the preset to register with.

**Return type**
None

**Parameters**

- **name** (*str*)
- **preset** (*PluginPreset[P]*)

**property plugin_preset: Optional[*PluginPreset*[P]]**

Get the current active plugin preset

**property has_plugin_preset: bool**

Check whether or not there is a plugin preset in use on this hub right now

**use_plugin_preset**(*preset*)

Apply a preset to the hub. If there was a previously active preset, discard it.

Preset can be either the string name of a preset or a PluginPreset instance.

**Return type**
None

**Parameters**
**preset** (*str | PluginPreset[P]*)

**discard_plugin_preset**()

Discard the current active preset. Will release any active plugins that could have come from the old preset.

**Return type**
None

**get_plugin**(*name*)

Get the plugin named `name`. If no such plugin is currently active, try to activate a new one using the current preset.

**Return type**
P

**Parameters**
**name** (*str*)

**has_plugin**(*name*)

Return whether or not a plugin with the name `name` is currently active.

**Return type**
bool

**Parameters**
**name** (*str*)

`register_plugin`(*name*, *plugin*)

Add a new plugin `plugin` with name `name` to the active plugins.

**Return type**
P

**Parameters**

- **name** (*str*)
- **plugin** (*P*)

`release_plugin`(*name*)

Deactivate and remove the plugin with name `name`.

**Return type**
None

**Parameters**
**name** (*str*)

class angr.misc.plugins.**PluginPreset**

Bases: Generic[P]

A plugin preset object contains a mapping from name to a plugin class. A preset can be active on a hub, which will cause it to handle requests for plugins which are not already present on the hub.

Unlike Plugins and PluginHubs, instances of PluginPresets are defined on the module level for individual presets. You should register the preset instance with a hub to allow plugins to easily add themselves to the preset without an explicit reference to the preset itself.

`__init__`()

**Return type**
None

`activate`(*hub*)

This method is called when the preset becomes active on a hub.

**Return type**
None

**Parameters**
**hub** (PluginHub*[P]*)

`deactivate`(*hub*)

This method is called when the preset is discarded from the hub.

**Return type**
None

**Parameters**
**hub** (PluginHub*[P]*)

`add_default_plugin`(*name*, *plugin_cls*)

Add a plugin to the preset.

**Return type**
None

**Parameters**

- **name** (*str*)

- **plugin_cls** (*type[P]*)

**list_default_plugins**()

Return a list of the names of available default plugins.

**Return type**
list[str]

**request_plugin**(*name*)

Return the plugin class which is registered under the name `name`, or raise NoPlugin if the name isn't available.

**Return type**
type[P]

**Parameters**
**name** (*str*)

**copy**()

Return a copy of self.

**Return type**
*PluginPreset*[P]

**class** angr.misc.plugins.**PluginVendor**

Bases: *PluginHub*[P], Generic[P]

A specialized hub which serves only as a plugin vendor, never having any "active" plugins. It will directly return the plugins provided by the preset instead of instantiating them.

**release_plugin**(*name*)

This hub doesn't actually have any active plugins, so this is a no-op.

**Return type**
None

**Parameters**
**name** (*str*)

**register_plugin**(*name*, *plugin*)

This hub doesn't actually have any active plugins, so this is a no-op. We just return the plugin that was passed in to satisfy the return type of PluginHub.register_plugin.

**Return type**
P

**Parameters**

- **name** (*str*)
- **plugin** (*P*)

**class** angr.misc.plugins.**VendorPreset**

Bases: *PluginPreset*[P], Generic[P]

A specialized preset class for use with the PluginVendor.

### 10.28.8 angr.misc.telemetry

class angr.misc.telemetry.**Status**

Bases: object

Represents the status of a finished Span.

**Parameters**

- **status_code** () – The canonical status code that describes the result status of the operation.
- **description** (str | None) – An optional description of the status.

**__init__**(*status_code=StatusCode.UNSET*, *description=None*)

**Parameters**

- **status_code** (*StatusCode*)
- **description** (*str | None*)

property **status_code: StatusCode**

Represents the canonical status code of a finished Span.

property **description: str | None**

Status description

property **is_ok: bool**

Returns false if this represents an error, true otherwise.

property **is_unset: bool**

Returns true if unset, false otherwise.

class angr.misc.telemetry.**StatusCode**

Bases: Enum

Represents the canonical set of status codes of a finished Span.

**UNSET = 0**

The default status.

**OK = 1**

The operation has been validated by an Application developer or Operator to have completed successfully.

**ERROR = 2**

The operation contains an error.

angr.misc.telemetry.**get_current_span**(*context=None*)

Retrieve the current span.

**Parameters**

**context** (Context | None) – A Context object. If one is not passed, the default current context is used instead.

**Return type**

**Returns**

The Span set in the context if it exists. INVALID_SPAN otherwise.

angr.misc.telemetry.**get_tracer**(*name*)

**Return type**

Tracer

**Parameters**
**name** (*str*)

### 10.28.9 angr.misc.testing

angr.misc.testing.**detect_test_env**()

### 10.28.10 angr.misc.ux

angr.misc.ux.**once**(*key*)

**Return type**
bool

**Parameters**
**key** (*str*)

angr.misc.ux.**deprecated**[*R*, **P*](*replacement=None*)

**Return type**
Callable[[Callable[P, R]], Callable[P, R]]

**Parameters**
**replacement** (*str | None*)

## 10.29 angr.procedures

### Submodules

### 10.29.3 angr.procedures.definitions

**class** angr.procedures.definitions.**SimTypeCollection**

Bases: object

A type collection is the mechanism for describing types. Types in a type collection can be referenced using

**__init__**()

**set_names**(**names*)

**Parameters**
**names** (*str*)

**add**(*name*, *t*)

Add a type to the collection.

**Parameters**

- **name** (*str*) – Name of the type to add.
- **t** (*SimType*) – The SimType object to add to the collection.

**Return type**
None

**get**(*name*, *bottom_on_missing=False*, *memo=None*)

Get a SimType object from the collection as identified by the name.

**Parameters**

- **name** (*str*) – Name of the type to get.
- **bottom_on_missing** (*bool*) – Return a SimTypeBottom object if the required type does not exist.
- **memo** (*set[str] | None*) – A set of names that have been queried in this call chain (to prevent infinite recursion).

**Return type**
*SimType*

**Returns**
The SimType object.

**init_str**()

**Return type**
str

to_json(*types_as_string=False*)

**Return type**
dict[str, Any]

**Parameters**
**types_as_string** (*bool*)

classmethod from_json(*d*)

**Return type**
*SimTypeCollection*

**Parameters**
**d** (*dict[str, Any]*)

class angr.procedures.definitions.**SimLibrary**

Bases: object

A SimLibrary is the mechanism for describing a dynamic library's API, its functions and metadata.

Any instance of this class (or its subclasses) found in the angr.procedures.definitions package will be automatically picked up and added to angr.SIM_LIBRARIES via all its names.

**Variables**

- **fallback_cc** – A mapping from architecture to the default calling convention that should be used if no other information is present. Contains some sane defaults for linux.
- **fallback_proc** – A SimProcedure class that should be used to provide stub procedures. By default, ReturnUnconstrained.

__init__()

static from_json(*d*)

**Return type**
*SimLibrary*

**Parameters**
**d** (*dict[str, Any]*)

copy()

Make a copy of this SimLibrary, allowing it to be mutated without affecting the global version.

**Returns**
A new SimLibrary object with the same library references but different dict/list references

update(*other*)

Augment this SimLibrary with the information from another SimLibrary

**Parameters**
**other** (*SimLibrary*) – The other SimLibrary

property name

The first common name of this library, e.g. libc.so.6, or '??????' if none are known.

set_library_names(**names*)

Set some common names of this library by which it may be referred during linking

**Parameters**
**names** – Any number of string library names may be passed as varargs.

**set_default_cc**(*arch_name*, *cc_cls*)

Set the default calling convention used for this library under a given architecture

**Parameters**
**arch_name** – The string name of the architecture, i.e. the .name field from archinfo.

**Parm cc_cls**
The SimCC class (not an instance!) to use

**set_non_returning**(**names*)

Mark some functions in this class as never returning, i.e. loops forever or terminates execution

**Parameters**
**names** – Any number of string function names may be passed as varargs

**set_prototype**(*name*, *proto*)

Set the prototype of a function in the form of a SimTypeFunction containing argument and return types

**Parameters**

- **name** – The name of the function as a string
- **proto** (*SimTypeFunction*) – The prototype of the function as a SimTypeFunction

**Return type**
None

**set_prototypes**(*protos*)

Set the prototypes of many functions

**Parameters**
**protos** (dict[str, *SimTypeFunction*]) – Dictionary mapping function names to SimTypeFunction objects

**Return type**
None

**set_c_prototype**(*c_decl*)

Set the prototype of a function in the form of a C-style function declaration.

**Parameters**
**c_decl** (str) – The C-style declaration of the function.

**Return type**
tuple[str, *SimTypeFunction*]

**Returns**
A tuple of (function name, function prototype)

**add**(*name*, *proc_cls*, ***kwargs*)

Add a function implementation to the library.

**Parameters**

- **name** – The name of the function as a string
- **proc_cls** – The implementation of the function as a SimProcedure _class_, not instance
- **kwargs** – Any additional parameters to the procedure class constructor may be passed as kwargs

**add_all_from_dict**(*dictionary*, ***kwargs*)

Batch-add function implementations to the library.

**Parameters**

- **dictionary** – A mapping from name to procedure class, i.e. the first two arguments to add()
- **kwargs** – Any additional kwargs will be passed to the constructors of _each_ procedure class

**add_alias**(*name*, **alt_names*)

Add some duplicate names for a given function. The original function's implementation must already be registered.

**Parameters**

- **name** – The name of the function for which an implementation is already present
- **alt_names** – Any number of alternate names may be passed as varargs

**get**(*name*, *arch*)

Get an implementation of the given function specialized for the given arch, or a stub procedure if none exists.

**Parameters**

- **name** – The name of the function as a string
- **arch** – The architecure to use, as either a string or an archinfo.Arch instance

**Returns**
A SimProcedure instance representing the function as found in the library

**get_stub**(*name*, *arch*)

Get a stub procedure for the given function, regardless of if a real implementation is available. This will apply any metadata, such as a default calling convention or a function prototype.

By stub, we pretty much always mean a `ReturnUnconstrained` SimProcedure with the appropriate display name and metadata set. This will appear in `state.history.descriptions` as `<SimProcedure display_name (stub)>`

**Parameters**

- **name** – The name of the function as a string
- **arch** – The architecture to use, as either a string or an archinfo.Arch instance

**Returns**
A SimProcedure instance representing a plausable stub as could be found in the library.

**get_prototype**(*name*, *arch=None*, *deref=False*)

Get a prototype of the given function name, optionally specialize the prototype to a given architecture.

**Parameters**

- **name** (str) – Name of the function.
- **arch** – The architecture to specialize to.
- **deref** (bool) – True if any SimTypeRefs in the prototype should be dereferenced using library information.

**Return type**
*SimTypeFunction* | None

**Returns**
Prototype of the function, or None if the prototype does not exist.

`has_metadata`(*name*)

Check if a function has either an implementation or any metadata associated with it

**Parameters**
**name** – The name of the function as a string

**Returns**
A bool indicating if anything is known about the function

`has_implementation`(*name*)

Check if a function has an implementation associated with it

**Parameters**
**name** – The name of the function as a string

**Returns**
A bool indicating if an implementation of the function is available

`has_prototype`(*func_name*)

Check if a function has a prototype associated with it.

A prototype that is explicitly registered as `None` (i.e. the function is known but its signature is not) does not count: this keeps `has_prototype()` consistent with `get_prototype()`, which returns `None` for such entries.

**Parameters**
**func_name** (*str*) – The name of the function.

**Returns**
A bool indicating if a prototype of the function is available.

**Return type**
bool

`is_returning`(*name*)

Check if a function is known to return.

**Parameters**
**name** (`str`) – The name of the function.

**Return type**
`bool`

**Returns**
A bool indicating if the function is known to return or not.

`class angr.procedures.definitions.SimCppLibrary`

Bases: *SimLibrary*

SimCppLibrary is a specialized version of SimLibrary that will demangle C++ function names before looking for an implementation or prototype for it.

`get`(*name*, *arch*)

Get an implementation of the given function specialized for the given arch, or a stub procedure if none exists. Demangle the function name if it is a mangled C++ name.

**Parameters**

- **name** (*str*) – The name of the function as a string

- **arch** – The architecure to use, as either a string or an archinfo.Arch instance

**Returns**
A SimProcedure instance representing the function as found in the library

`get_stub`(*name*, *arch*)

Get a stub procedure for the given function, regardless of if a real implementation is available. This will apply any metadata, such as a default calling convention or a function prototype. Demangle the function name if it is a mangled C++ name.

**Parameters**

- **name** (*str*) – The name of the function as a string
- **arch** – The architecture to use, as either a string or an archinfo.Arch instance

**Returns**
A SimProcedure instance representing a plausable stub as could be found in the library.

`get_prototype`(*name*, *arch=None*, *deref=False*)

Get a prototype of the given function name, optionally specialize the prototype to a given architecture. The function name will be demangled first.

**Parameters**

- **name** (str) – Name of the function.
- **arch** – The architecture to specialize to.
- **deref** (bool) – True if any SimTypeRefs in the prototype should be dereferenced using library information.

**Return type**
*SimTypeFunction* | None

**Returns**
Prototype of the function, or None if the prototype does not exist.

`has_metadata`(*name*)

Check if a function has either an implementation or any metadata associated with it. Demangle the function name if it is a mangled C++ name.

**Parameters**
**name** – The name of the function as a string

**Returns**
A bool indicating if anything is known about the function

`has_implementation`(*name*)

Check if a function has an implementation associated with it. Demangle the function name if it is a mangled C++ name.

**Parameters**
**name** (*str*) – A mangled function name.

**Returns**
bool

`has_prototype`(*func_name*)

Check if a function has a prototype associated with it. Demangle the function name if it is a mangled C++ name.

**Parameters**
**name** (*str*) – A mangled function name.

**Returns**
bool

**class** angr.procedures.definitions.**SimSyscallLibrary**

Bases: *SimLibrary*

SimSyscallLibrary is a specialized version of SimLibrary for dealing not with a dynamic library's API but rather an operating system's syscall API. Because this interface is inherently lower-level than a dynamic library, many parts of this class has been changed to store data based on an "ABI name" (ABI = application binary interface, like an API but for when there's no programming language) instead of an architecture. An ABI name is just an arbitrary string with which a calling convention and a syscall numbering is associated.

All the SimLibrary methods for adding functions still work, but now there's an additional layer on top that associates them with numbers.

**__init__**()

**minimum_syscall_number**(*abi*)

**Parameters**
**abi** – The abi to evaluate

**Returns**
The smallest syscall number known for the given abi

**maximum_syscall_number**(*abi*)

**Parameters**
**abi** – The abi to evaluate

**Returns**
The largest syscall number known for the given abi

**add_number_mapping**(*abi*, *number*, *name*)

Associate a syscall number with the name of a function present in the underlying SimLibrary

**Parameters**

- **abi** – The abi for which this mapping applies
- **number** – The syscall number
- **name** – The name of the function

**add_number_mapping_from_dict**(*abi*, *mapping*)

Batch-associate syscall numbers with names of functions present in the underlying SimLibrary

**Parameters**

- **abi** – The abi for which this mapping applies
- **mapping** – A dict mapping syscall numbers to function names

**set_abi_cc**(*abi*, *cc_cls*)

Set the default calling convention for an abi

**Parameters**

- **abi** – The name of the abi
- **cc_cls** – A SimCC _class_, not an instance, that should be used for syscalls using the abi

**set_prototype**(*abi*, *name*, *proto*)

Set the prototype of a function in the form of a SimTypeFunction containing argument and return types

**Parameters**

- **abi** (str) – ABI of the syscall.
- **name** (str) – The name of the syscall as a string
- **proto** (*SimTypeFunction*) – The prototype of the syscall as a SimTypeFunction

**Return type**
None

**set_prototypes**(*abi*, *protos*)

Set the prototypes of many syscalls.

**Parameters**

- **abi** (str) – ABI of the syscalls.
- **protos** (dict[str, *SimTypeFunction*]) – Dictionary mapping syscall names to SimTypeFunction objects

**Return type**
None

**add_alias**(*name*, **alt_names*)

Add some duplicate names for a given function. The original function's implementation must already be registered.

**Parameters**

- **name** – The name of the function for which an implementation is already present
- **alt_names** – Any number of alternate names may be passed as varargs

**get**(*number*, *arch*, *abi_list=()*)

The get() function for SimSyscallLibrary looks a little different from its original version.

Instead of providing a name, you provide a number, and you additionally provide a list of abi names that are applicable. The first abi for which the number is present in the mapping will be chosen. This allows for the easy abstractions of architectures like ARM or MIPS linux for which there are many ABIs that can be used at any time by using syscall numbers from various ranges. If no abi knows about the number, the stub procedure with the name "sys_%d" will be used.

**Parameters**

- **number** – The syscall number
- **arch** – The architecture being worked with, as either a string name or an archinfo.Arch
- **abi_list** – A list of ABI names that could be used

**Returns**
A SimProcedure representing the implementation of the given syscall, or a stub if no implementation is available

**get_stub**(*number*, *arch*, *abi_list=()*)

Pretty much the intersection of SimLibrary.get_stub() and SimSyscallLibrary.get().

**Parameters**

- **number** – The syscall number

- **arch** – The architecture being worked with, as either a string name or an archinfo.Arch
- **abi_list** – A list of ABI names that could be used

**Returns**
A SimProcedure representing a plausable stub that could model the syscall

**get_prototype**(*abi*, *name*, *arch=None*, *deref=False*)

Get a prototype of the given syscall name and its ABI, optionally specialize the prototype to a given architecture.

**Parameters**

- **abi** (str) – ABI of the prototype to get.
- **name** (str) – Name of the syscall.
- **arch** – The architecture to specialize to.
- **deref** (bool) – True if any SimTypeRefs in the prototype should be dereferenced using library information.

**Return type**
*SimTypeFunction* | None

**Returns**
Prototype of the syscall, or None if the prototype does not exist.

**has_metadata**(*number*, *arch*, *abi_list=()*)

Pretty much the intersection of SimLibrary.has_metadata() and SimSyscallLibrary.get().

**Parameters**

- **number** – The syscall number
- **arch** – The architecture being worked with, as either a string name or an archinfo.Arch
- **abi_list** – A list of ABI names that could be used

**Returns**
A bool of whether or not any implementation or metadata is known about the given syscall

**has_implementation**(*number*, *arch*, *abi_list=()*)

Pretty much the intersection of SimLibrary.has_implementation() and SimSyscallLibrary.get().

**Parameters**

- **number** – The syscall number
- **arch** – The architecture being worked with, as either a string name or an archinfo.Arch
- **abi_list** – A list of ABI names that could be used

**Returns**
A bool of whether or not an implementation of the syscall is available

**has_prototype**(*abi*, *name*)

Check if a function has a prototype associated with it. Demangle the function name if it is a mangled C++ name.

Syscalls whose signature is unknown are registered with a `None` prototype (see, e.g., `capset` in `linux_kernel.py`). Those do not count as having a prototype: this keeps `has_prototype()` consistent with `get_prototype()`, which returns `None` for such entries.

**Parameters**

- **abi** (str) – Name of the ABI.
- **name** (str) – The syscall name.

**Return type**
bool

**Returns**
bool

angr.procedures.definitions.**load_type_collections**(*only=None*, *skip=None*)

**Return type**
None

angr.procedures.definitions.**load_win32_type_collections**()

**Return type**
None

angr.procedures.definitions.**load_external_definitions**()

Load library definitions from specific directories. By default it parses ANGR_EXTERNAL_DEFINITIONS_DIRS as a semicolon separated list of directory paths. Then it loads all .py files in each directory. These .py files should declare SimLibrary() objects and call .set_library_names() to register themselves in angr.SIM_LIBRARIES.

angr.procedures.definitions.**load_win32api_definitions**()

angr.procedures.definitions.**load_all_definitions**()

### angr.procedures.definitions.cgc

### angr.procedures.definitions.freebsd_kernel

FreeBSD's native syscall interface.

The numbering is `sys/sys/syscall.h` at freebsd/freebsd-src f9716eee8ab45ad906d9b5c5233ca20c10226ca7 (release/14.0.0), generated there from `sys/kern/syscalls.master`, plus the COMPAT4 and COMPAT6 numbers that header does not export and a kernel built from `GENERIC` still dispatches, since both amd64 and i386 enable `COMPAT_FREEBSD4` and `COMPAT_FREEBSD6`. FreeBSD numbers its native syscalls identically on every architecture, so one ABI covers them all; what changes between architectures is where the arguments sit, which `SYSCALL_CC` supplies.

Each number carries the name `syscalls.master` declares for it. Where several numbers declare one name – `fstat` at

189 and 551, `statfs` at 157, 396 and 555 – the name goes to the one that is not a compatibility entry and the rest keep the `freebsd<N>_` spelling the kernel's own `sysent` gives them, so that no two numbers share a name. A compatibility entry whose name nothing else claims keeps that name: 272 is `getdents`, not `freebsd11_getdents`, and 164 is `uname`.

FreeBSD implements the POSIX calls angr already models, so the procedures here are the ones angr ships for the Linux kernel. Only the numbering and the argument locations are FreeBSD's own, and those are what this library and `SYSCALL_CC` supply.

### angr.procedures.definitions.types_stl

angr.procedures.definitions.types_stl.**EXACTDIV_ELEMENT_SIZES** = (3, 5, 6, 7, 9, 10, 11, 12, 13, 14, 15, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511)

Element sizes for which an opaque `std::vector<T<N>>` class exists.

The std::vector<T>::size() exact-division patterns (see analyses/decompiler/known_patterns/std_vector_size.py) recover sizeof(T) from the compiler's magic constant but not the element type, so each supported size gets an opaque N-byte element class named `T<N>`. Only non-power-of-two sizes are listed: a power-of-two sizeof(T) divides with a bare shift and needs no magic constant (those are the named std::vector<short/int/long long> templates). The upper bound is empirical: real containers of large records exist (CryptoPP::ECPPoint is 112 bytes, and vectors of 100+ byte structs are common in C++ code), and covering only a handful of small sizes leaves the pattern silent on the code where the raw magic multiply is least readable.

angr.procedures.definitions.types_stl.**SHIFT_ELEMENT_SIZES** = (16, 32, 64, 128, 256, 512)

Power-of-two element sizes above 8, which divide with a bare shift but have no named C++ type of that width (short/int/long long cover 2/4/8).

Leaving these out mattered: sizeof(std::string) is 32 on libstdc++, and std::vector<std::string> is the single most common element type in the benchmark corpus. Without a T32 template its size() read is either unnamed or, worse, misidentified by whatever sub-pattern does match.

angr.procedures.definitions.types_stl.**OPAQUE_ELEMENT_SIZES** = (3, 5, 6, 7, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512)

Every size with an opaque `std::vector<T<N>>` class.

### 10.29.4 angr.procedures.glibc

These procedures implement internal functions for the GNU libc that commonly appears on linux systems

#### Submodules

| |
|---|
| *dynamic_loading* |
| *scanf* |
| *sscanf* |

#### angr.procedures.glibc.dynamic_loading

#### angr.procedures.glibc.scanf

#### angr.procedures.glibc.sscanf

### 10.29.5 angr.procedures.gnulib

These procedures implement functions described in the gnulib library: https://www.gnu.org/software/gnulib/

### Submodules

*xalloc_die*
*xstrtol_fatal*

#### angr.procedures.gnulib.xalloc_die

**class** angr.procedures.gnulib.xalloc_die.**xalloc_die**

Bases: *SimProcedure*

**class** angr.procedures.libc.strtok.**strtok**

Bases: *SimProcedure*

**KEY = 'strtok_save_ptr'**

### angr.procedures.libc.strtol

**class** angr.procedures.libc.strtol.**strtol**

Bases: *SimProcedure*

**static strtol_inner**(*s*, *state*, *region*, *base*, *signed*, *read_length=None*)

Inner parser for strtol-style functions.

Note: all numbers may start with +/- and base 16 may start with 0x.

**Parameters**

- **s** – the string address/offset
- **state** – SimState
- **region** – memory, file, etc
- **base** – the base to use to interpret the number
- **signed** – boolean, true means the result will be signed, otherwise unsigned
- **read_length** – int, the number of bytes parsed in strtol

**Returns**

`(expression, value, num_bytes)` where `expression` is a symbolic boolean indicating success, `value` is the returned value (set to 0 on failure, or min/max on overflow), and `num_bytes` is the number of bytes read in the string.

**static strtol_inner_auto**(*s*, *state*, *region*, *signed*, *read_length=None*)

strtol_inner with base 0: base 16 after a 0x/0X prefix, 8 after a leading 0, and 10 otherwise.

### angr.procedures.libc.strtoul

**class** angr.procedures.libc.strtoul.**strtoul**

Bases: *SimProcedure*

### angr.procedures.libc.strxfrm

**class** angr.procedures.libc.strxfrm.**strxfrm**

Bases: *SimProcedure*

Transform string for locale-aware comparison.

### angr.procedures.libc.system

**class** angr.procedures.libc.system.**system**

Bases: *SimProcedure*

### angr.procedures.libc.time

**class** angr.procedures.libc.time.**time**

Bases: *SimProcedure*

### angr.procedures.libc.tmpnam

**class** angr.procedures.libc.tmpnam.**tmpnam**

Bases: *SimProcedure*

### angr.procedures.libc.tolower

**class** angr.procedures.libc.tolower.**tolower**

Bases: *SimProcedure*

### angr.procedures.libc.toupper

**class** angr.procedures.libc.toupper.**toupper**

Bases: *SimProcedure*

### angr.procedures.libc.ungetc

**class** angr.procedures.libc.ungetc.**ungetc**

Bases: *SimProcedure*

### angr.procedures.libc.vfprintf

**class** angr.procedures.libc.vfprintf.**vfprintf**

Bases: *SimProcedure*

### angr.procedures.libc.vprintf

angr.procedures.libc.vprintf.**unmodeled_format_length**(*proc*, *fmt*)

Return strlen(fmt) for a v*printf procedure, which copies its format as is: angr does not model va_list, so conversions are not substituted. Warns once per procedure when a concrete format contains a '%'.

**Parameters**
**proc** (SimProcedure)

angr.procedures.libc.vprintf.**as_return**(*proc*, *value*)

Fit a length to the procedure's return type: glibc declares the v*printf family as returning int.

**Parameters**
**proc** (SimProcedure)

class angr.procedures.libc.vprintf.**vprintf**

Bases: *SimProcedure*

#### angr.procedures.libc.vsnprintf

class angr.procedures.libc.vsnprintf.**vsnprintf**

Bases: *SimProcedure*

#### angr.procedures.libc.vsprintf

class angr.procedures.libc.vsprintf.**vsprintf**

Bases: *SimProcedure*

#### angr.procedures.libc.wchar

class angr.procedures.libc.wchar.**wcscmp**

Bases: *SimProcedure*

class angr.procedures.libc.wchar.**wcscasecmp**

Bases: *SimProcedure*

### 10.29.12 angr.procedures.libstdcpp

#### Submodules

### angr.procedures.linux_kernel.access

**class** angr.procedures.linux_kernel.access.**access**

Bases: *SimProcedure*

### angr.procedures.linux_kernel.arch_prctl

**class** angr.procedures.linux_kernel.arch_prctl.**arch_prctl**

Bases: *SimProcedure*

Sets the architecture specific thread state based on the subfunction selected using the 'code' parameter. This syscall is only present on x86_64 linux

### angr.procedures.linux_kernel.arm_user_helpers

### angr.procedures.linux_kernel.brk

**class** angr.procedures.linux_kernel.brk.**brk**

Bases: *SimProcedure*

This implements the brk system call.

### angr.procedures.linux_kernel.cwd

**class** angr.procedures.linux_kernel.cwd.**getcwd**

Bases: *SimProcedure*

**class** angr.procedures.linux_kernel.cwd.**chdir**

Bases: *SimProcedure*

### angr.procedures.linux_kernel.fstat

**class** angr.procedures.linux_kernel.fstat.**fstat**

Bases: *SimProcedure*

Bases: *SimProcedure*

**class** angr.procedures.linux_kernel.getegid.**getegid32**

Bases: *SimProcedure*

### angr.procedures.linux_kernel.geteuid

**class** angr.procedures.linux_kernel.geteuid.**geteuid**

Bases: *SimProcedure*

**class** angr.procedures.linux_kernel.geteuid.**geteuid32**

Bases: *SimProcedure*

### angr.procedures.linux_kernel.getgid

**class** angr.procedures.linux_kernel.getgid.**getgid**

Bases: *SimProcedure*

**class** angr.procedures.linux_kernel.getgid.**getgid32**

Bases: *SimProcedure*

### angr.procedures.linux_kernel.getpid

**class** angr.procedures.linux_kernel.getpid.**getpid**

Bases: *SimProcedure*

**class** angr.procedures.linux_kernel.getpid.**getppid**

Bases: *SimProcedure*

### angr.procedures.linux_kernel.getrlimit

**class** angr.procedures.linux_kernel.getrlimit.**getrlimit**

Bases: *SimProcedure*

**class** angr.procedures.linux_kernel.getrlimit.**ugetrlimit**

Bases: *getrlimit*

### angr.procedures.linux_kernel.gettid

**class** angr.procedures.linux_kernel.gettid.**gettid**

Bases: *SimProcedure*

### angr.procedures.linux_kernel.getuid

**class** angr.procedures.linux_kernel.getuid.**getuid**

Bases: *SimProcedure*

**class** angr.procedures.linux_kernel.getuid.**getuid32**

Bases: *SimProcedure*

### angr.procedures.linux_kernel.iovec

class angr.procedures.linux_kernel.iovec.**readv**

Bases: *SimProcedure*

class angr.procedures.linux_kernel.iovec.**writev**

Bases: *SimProcedure*

### angr.procedures.linux_kernel.lseek

class angr.procedures.linux_kernel.lseek.**lseek**

Bases: *SimProcedure*

### angr.procedures.linux_kernel.mmap

class angr.procedures.linux_kernel.mmap.**old_mmap**

Bases: *mmap*

class angr.procedures.linux_kernel.mmap.**mmap2**

Bases: *mmap*

### angr.procedures.linux_kernel.mprotect

class angr.procedures.linux_kernel.mprotect.**mprotect**

Bases: *SimProcedure*

### angr.procedures.linux_kernel.munmap

class angr.procedures.linux_kernel.munmap.**munmap**

Bases: *SimProcedure*

### angr.procedures.linux_kernel.openat

class angr.procedures.linux_kernel.openat.**openat**

Bases: *SimProcedure*

### angr.procedures.linux_kernel.set_tid_address

class angr.procedures.linux_kernel.set_tid_address.**set_tid_address**

Bases: *SimProcedure*

### angr.procedures.linux_kernel.sigaction

class angr.procedures.linux_kernel.sigaction.**sigaction**

Bases: *SimProcedure*

class angr.procedures.linux_kernel.sigaction.**rt_sigaction**

Bases: *SimProcedure*

### angr.procedures.linux_kernel.sigprocmask

class angr.procedures.linux_kernel.sigprocmask.**sigprocmask**

Bases: *SimProcedure*

#### angr.procedures.linux_kernel.stat

class angr.procedures.linux_kernel.stat.**stat**

Bases: *fstat*

#### angr.procedures.linux_kernel.sysinfo

class angr.procedures.linux_kernel.sysinfo.**sysinfo**

Bases: *SimProcedure*

#### angr.procedures.linux_kernel.tgkill

class angr.procedures.linux_kernel.tgkill.**tgkill**

Bases: *SimProcedure*

#### angr.procedures.linux_kernel.time

class angr.procedures.linux_kernel.time.**time**

Bases: *SimProcedure*

**KEY = 'sys_last_time'**

**property last_time**

#### angr.procedures.linux_kernel.uid

class angr.procedures.linux_kernel.uid.**getuid**

Bases: *SimProcedure*

class angr.procedures.linux_kernel.uid.**getgid**

Bases: *SimProcedure*

class angr.procedures.linux_kernel.uid.**getresgid**

Bases: *SimProcedure*

class angr.procedures.linux_kernel.uid.**getresuid**

Bases: *SimProcedure*

#### angr.procedures.linux_kernel.uname

class angr.procedures.linux_kernel.uname.**uname**

Bases: *SimProcedure*

#### angr.procedures.linux_kernel.unlink

class angr.procedures.linux_kernel.unlink.**unlink**

Bases: *SimProcedure*

#### angr.procedures.linux_kernel.vsyscall

### 10.29.14 angr.procedures.linux_loader

These function implement functions or other functionalities provided by the linux userspace dynamic loader

#### Submodules

*sim_loader*
*tls*

#### angr.procedures.linux_loader.sim_loader

**class** angr.procedures.linux_loader.sim_loader.**LinuxLoader**

Bases: *SimProcedure*

**NO_RET = True**

**local_vars: tuple[str, ...] = ('initializers',)**

**run_initializer**()

**class** angr.procedures.linux_loader.sim_loader.**IFuncResolver**

Bases: *SimProcedure*

**NO_RET = True**

**local_vars: tuple[str, ...] = ('saved_regs',)**

**after_call**(*funcaddr=None*)

#### angr.procedures.linux_loader.tls

**class** angr.procedures.linux_loader.tls.**tlsdesc_resolver**

Bases: *SimProcedure*

### 10.29.15 angr.procedures.msvcr

These functions implement those found in the various versions of msvcr.dll (Microsoft Visual C/C++ Runtime)

#### Submodules

*fmode*

#### angr.procedures.msvcr.fmode

### 10.29.16 angr.procedures.ntdll

#### Submodules

*exceptions*

#### angr.procedures.ntdll.exceptions

**class** angr.procedures.ntdll.exceptions.**KiUserExceptionDispatcher**

Bases: *SimProcedure*

**local_vars: tuple[str, ...] = ('tib_ptr', 'top_record', 'cur_ptr')**

**IS_FUNCTION = False**

**tib_ptr = None**

**top_record = None**

**cur_ptr = None**

**dispatch**(*record*, *context*)

### 10.29.17 angr.procedures.posix

These procedures implement functions described in POSIX.1

#### Submodules

### angr.procedures.posix.accept

**class** angr.procedures.posix.accept.**accept**

Bases: *SimProcedure*

### angr.procedures.posix.bind

**class** angr.procedures.posix.bind.**bind**

Bases: *SimProcedure*

### angr.procedures.posix.bzero

**class** angr.procedures.posix.bzero.**bzero**

Bases: *memset*

### angr.procedures.posix.chroot

**class** angr.procedures.posix.chroot.**chroot**

Bases: *SimProcedure*

Changes the root directory of the emulated filesystem (`state.fs`) to the given path.

The new root is resolved inside the filesystem the state already has, so this can only narrow what the guest is able to reach.

### angr.procedures.posix.close

**class** angr.procedures.posix.close.**close**

Bases: *SimProcedure*

### angr.procedures.posix.closedir

**class** angr.procedures.posix.closedir.**closedir**

Bases: *close*

### angr.procedures.posix.dup

**class** angr.procedures.posix.dup.**dup**

Bases: *SimProcedure*

**class** angr.procedures.posix.dup.**dup2**

Bases: *SimProcedure*

**class** angr.procedures.posix.dup.**dup3**

Bases: *SimProcedure*

### angr.procedures.posix.fcntl

class angr.procedures.posix.fcntl.**fcntl**

Bases: *SimProcedure*

### angr.procedures.posix.fdopen

angr.procedures.posix.fdopen.**mode_to_flag**(*mode*)

angr.procedures.posix.fdopen.**create_file**(*mode*)

class angr.procedures.posix.fdopen.**fdopen**

Bases: *SimProcedure*

### angr.procedures.posix.fileno

class angr.procedures.posix.fileno.**fileno**

Bases: *SimProcedure*

angr.procedures.posix.fileno.**fileno_unlocked**

alias of *fileno*

### angr.procedures.posix.fork

class angr.procedures.posix.fork.**fork**

Bases: *SimProcedure*

### angr.procedures.posix.getenv

class angr.procedures.posix.getenv.**getenv**

Bases: *SimProcedure*

The getenv() function searches the environment list to find the environment variable name, and returns a pointer to the corresponding value string.

### angr.procedures.posix.gethostbyname

class angr.procedures.posix.gethostbyname.**gethostbyname**

Bases: *SimProcedure*

### angr.procedures.posix.getpass

class angr.procedures.posix.getpass.**getpass**

Bases: *SimProcedure*

### angr.procedures.posix.getsockopt

class angr.procedures.posix.getsockopt.**getsockopt**

Bases: *SimProcedure*

### angr.procedures.posix.htonl

class angr.procedures.posix.htonl.**htonl**

Bases: *SimProcedure*

### angr.procedures.posix.htons

class angr.procedures.posix.htons.**htons**

Bases: *SimProcedure*

### angr.procedures.posix.inet_ntoa

class angr.procedures.posix.inet_ntoa.**inet_ntoa**

Bases: *SimProcedure*

inet_ntoa simprocedure

**INET_INADDRSTRLEN = 16**

**run**(*addr_in*)

Run the simprocedure

**Parameters**

**addr_in** (*SimStructValue*) – inet_addr struct (which is just a 32-bit int)

### angr.procedures.posix.listen

class angr.procedures.posix.listen.**listen**

Bases: *SimProcedure*

### angr.procedures.posix.mmap

class angr.procedures.posix.mmap.**mmap**

Bases: *SimProcedure*

**allocate_memory**(*size*)

### angr.procedures.posix.open

class angr.procedures.posix.open.**open**

Bases: *SimProcedure*

### angr.procedures.posix.opendir

class angr.procedures.posix.opendir.**opendir**

Bases: *SimProcedure*

### angr.procedures.posix.poll

class angr.procedures.posix.poll.**poll**

Bases: *SimProcedure*

### angr.procedures.posix.pread64

class angr.procedures.posix.pread64.**pread64**

Bases: *SimProcedure*

### angr.procedures.posix.pthread

class angr.procedures.posix.pthread.**pthread_create**

Bases: *SimProcedure*

Simulates the new thread as an equally viable branch of symbolic execution.

**ADDS_EXITS = True**

**terminate_thread**(*thread*, *attr*, *start_routine*, *arg*)

class angr.procedures.posix.pthread.**pthread_cond_signal**

Bases: *SimProcedure*

A no-op.

class angr.procedures.posix.pthread.**pthread_mutex_lock**

Bases: *SimProcedure*

Always returns 0 (SUCCESS).

class angr.procedures.posix.pthread.**pthread_mutex_unlock**

Bases: *SimProcedure*

Always returns 0 (SUCCESS).

class angr.procedures.posix.pthread.**pthread_once**

Bases: *SimProcedure*

**retsite**(*control*, *func*)

### angr.procedures.posix.pwrite64

class angr.procedures.posix.pwrite64.**pwrite64**

Bases: *SimProcedure*

### angr.procedures.posix.read

class angr.procedures.posix.read.**read**

Bases: *SimProcedure*

### angr.procedures.posix.readdir

angr.procedures.posix.readdir.**Dirent**

alias of dirent

class angr.procedures.posix.readdir.**readdir**

Bases: *SimProcedure*

**struct = None**

**condition = None**

**instrument**()

Override this function to instrument the SimProcedure.

The two useful variables you can override are self.struct, a named tuple of all the struct fields, and self.condition, the condition for whether the function succeeds.

#### angr.procedures.posix.recv

class angr.procedures.posix.recv.**recv**

Bases: *SimProcedure*

#### angr.procedures.posix.recvfrom

class angr.procedures.posix.recvfrom.**recvfrom**

Bases: *SimProcedure*

#### angr.procedures.posix.select

class angr.procedures.posix.select.**select**

Bases: *SimProcedure*

#### angr.procedures.posix.send

class angr.procedures.posix.send.**send**

Bases: *SimProcedure*

#### angr.procedures.posix.setsockopt

class angr.procedures.posix.setsockopt.**setsockopt**

Bases: *SimProcedure*

#### angr.procedures.posix.sigaction

class angr.procedures.posix.sigaction.**sigaction**

Bases: *SimProcedure*

#### angr.procedures.posix.sim_time

class angr.procedures.posix.sim_time.**gettimeofday**

Bases: *SimProcedure*

class angr.procedures.posix.sim_time.**clock_gettime**

Bases: *SimProcedure*

#### angr.procedures.posix.sleep

class angr.procedures.posix.sleep.**sleep**

Bases: *SimProcedure*

#### angr.procedures.posix.socket

class angr.procedures.posix.socket.**socket**

Bases: *SimProcedure*

#### angr.procedures.posix.strcasecmp

class angr.procedures.posix.strcasecmp.**strcasecmp**

Bases: *SimProcedure*

#### angr.procedures.posix.strdup

class angr.procedures.posix.strdup.**strdup**

Bases: *SimProcedure*

#### angr.procedures.posix.strncasecmp

class angr.procedures.posix.strncasecmp.**strncasecmp**

Bases: *SimProcedure*

#### angr.procedures.posix.strndup

class angr.procedures.posix.strndup.**strndup**

Bases: *SimProcedure*

#### angr.procedures.posix.strtok_r

class angr.procedures.posix.strtok_r.**strtok_r**

Bases: *SimProcedure*

#### angr.procedures.posix.syslog

class angr.procedures.posix.syslog.**syslog**

Bases: *FormatParser*

#### angr.procedures.posix.tz

class angr.procedures.posix.tz.**tzset**

Bases: *SimProcedure*

#### angr.procedures.posix.unlink

class angr.procedures.posix.unlink.**unlink**

Bases: *SimProcedure*

#### angr.procedures.posix.usleep

class angr.procedures.posix.usleep.**usleep**

Bases: *SimProcedure*

#### angr.procedures.posix.write

class angr.procedures.posix.write.**write**

Bases: *SimProcedure*

### 10.29.18 angr.procedures.procedure_dict

### 10.29.19 angr.procedures.stubs

These procedures are various misc stubs useful in analysis

### Submodules

| |

**class** angr.procedures.stubs.Redirect.**Redirect**

Bases: *SimProcedure*

**NO_RET = True**

### angr.procedures.stubs.ReturnChar

class angr.procedures.stubs.ReturnChar.**ReturnChar**

Bases: *SimProcedure*

### angr.procedures.stubs.ReturnUnconstrained

class angr.procedures.stubs.ReturnUnconstrained.**ReturnUnconstrained**

Bases: *SimProcedure*

**ARGS_MISMATCH = True**

### angr.procedures.stubs.UnresolvableCallTarget

class angr.procedures.stubs.UnresolvableCallTarget.**UnresolvableCallTarget**

Bases: *SimProcedure*

**NO_RET = False**

### angr.procedures.stubs.UnresolvableJumpTarget

class angr.procedures.stubs.UnresolvableJumpTarget.**UnresolvableJumpTarget**

Bases: *SimProcedure*

**NO_RET = True**

### angr.procedures.stubs.UserHook

class angr.procedures.stubs.UserHook.**UserHook**

Bases: *SimProcedure*

**NO_RET = True**

### angr.procedures.stubs.b64_decode

class angr.procedures.stubs.b64_decode.**b64_decode**

Bases: *SimProcedure*

### angr.procedures.stubs.caller

class angr.procedures.stubs.caller.**Caller**

Bases: *SimProcedure*

Caller stub. Creates a Ijk_Call exit to the specified function

**after_call**(*target_addr=None*, *target_cc=None*)

### angr.procedures.stubs.crazy_scanf

class angr.procedures.stubs.crazy_scanf.**crazy_scanf**

Bases: *SimProcedure*

### angr.procedures.stubs.format_parser

**class** angr.procedures.stubs.format_parser.**FormatString**

Bases: object

Describes a format string.

**SCANF_DELIMITERS = [b'\t', b'\n', b'\x0b', b'\r', b' ']**

**__init__**(*parser*, *components*)

Takes a list of components which are either just strings or a FormatSpecifier.

**property state**

**replace**(*va_arg*)

Implement printf - based on the stored format specifier information, format the values from the arg getter function *args* into a string.

**Parameters**
**va_arg** – A function which takes a type and returns the next argument of that type

**Returns**
The result formatted string

**interpret**(*va_arg*, *addr=None*, *simfd=None*)

implement scanf - extract formatted data from memory or a file according to the stored format specifiers and store them into the pointers extracted from *args*.

**Parameters**

- **va_arg** – A function which, given a type, returns the next argument of that type
- **addr** – The address in the memory to extract data from, or…
- **simfd** – A file descriptor to use for reading data from

**Returns**
The number of arguments parsed

**class** angr.procedures.stubs.format_parser.**FormatSpecifier**

Bases: object

Describes a format specifier within a format string.

**__init__**(*sss*, *length_spec*, *pad_chr*, *ty*)

**Parameters**
**ty** (SimType)

**string**

**ty**

**length_spec**

**pad_chr**

**property signed**

**property size**

**property spec_type**

class angr.procedures.stubs.format_parser.**FormatParser**

Bases: *SimProcedure*

For SimProcedures relying on printf-style format strings.

**ARGS_MISMATCH = True**

**basic_spec = {b'A': double, b'E': double, b'F': double, b'G': double, b'X': unsigned int, b'a': double, b'c': char, b'd': int, b'e': double, b'f': double, b'g': double, b'i': int, b'n': unsigned int*, b'o': unsigned int, b'p': unsigned int*, b's': char*, b'u': unsigned int, b'x': unsigned int}**

**int_sign = {'signed': [b'd', b'i'], 'unsigned': [b'o', b'u', b'x', b'X']}**

**int_len_mod = {b'h': (short, unsigned short), b'hh': (char, char), b'j': (long long, unsigned long long), b'l': (long, unsigned long), b'll': (long long, unsigned long long), b't': (long, unsigned long), b'z': (size_t, size_t)}**

**float_spec = [b'e', b'E', b'f', b'F', b'g', b'G', b'a', b'A']**

**float_len_mod: dict[bytes, *SimType*] = {b'L': double, b'l': double, b'll': double}**

**other_types = {('string',): <function FormatParser.<lambda>>}**

**flags = ['#', '0', '\\-', ' ', '\\+', "\\'", 'I']**

**extract_components**(*fmt*)

Extract the actual formats from the format string *fmt*.

**Parameters**
**fmt** (list) – A list of format chars.

**Return type**
list[bytes | *FormatSpecifier*]

**Returns**
a FormatString object

class angr.procedures.stubs.format_parser.**ScanfFormatParser**

Bases: *FormatParser*

For SimProcedures relying on scanf-style format strings.

**basic_spec = {b'A': float, b'E': float, b'F': float, b'G': float, b'X': unsigned int, b'a': float, b'c': char, b'd': int, b'e': float, b'f': float, b'g': float, b'i': int, b'n': unsigned int*, b'o': unsigned int, b'p': unsigned int*, b's': char*, b'u': unsigned int, b'x': unsigned int}**

**float_len_mod: dict[bytes, *SimType*] = {b'L': double, b'l': double, b'll': double}**

### angr.procedures.stubs.syscall_stub

class angr.procedures.stubs.syscall_stub.**syscall**

Bases: *SimProcedure*

## 10.29.20 angr.procedures.testing

These procedures are used in the angr test suite. I'm like 90% sure they're unused at this point.

#### Submodules

*manyargs*
*retreg*

#### angr.procedures.testing.manyargs

**class** angr.procedures.testing.manyargs.**manyargs**

Bases: *SimProcedure*

**NO_RET = True**

#### angr.procedures.testing.retreg

**class** angr.procedures.testing.retreg.**retreg**

Bases: *SimProcedure*

### 10.29.21 angr.procedures.tracer

These procedures implement system calls for the cgc DECREE platform, in a specific way for tracing.

#### Submodules

*random*
*receive*
*transmit*

#### angr.procedures.tracer.random

**class** angr.procedures.tracer.random.**random**

Bases: *random*

This a passthrough to the CGC version. Removing this requires regenerating angrop caches used by rex and so this is being retained.

#### angr.procedures.tracer.receive

**class** angr.procedures.tracer.receive.**receive**

Bases: *receive*

Receive which fixes the input to file descriptor to 0.

#### angr.procedures.tracer.transmit

**class** angr.procedures.tracer.transmit.**transmit**

Bases: *transmit*

Transmit which fixes the output file descriptor to 1.

### 10.29.22 angr.procedures.uclibc

These procedures implement internal functions in the uClibc libc implementation

### 10.29.23 angr.procedures.win32

These procedures implement functions from the win32 api, notably kernel32.dll

#### Submodules

**fill_from_timestamp**(*ts*)

**fill_symbolic**()

class angr.procedures.win32.sim_time.**GetLocalTime**

Bases: *SimProcedure*

**wYear = None**

**wMonth = None**

**wDayOfWeek = None**

**wDay = None**

**wHour = None**

**wMinute = None**

**wSecond = None**

**wMilliseconds = None**

**instrument**()

Override this method, setting the class vars of the same names as the windows SYSTEMTIME structure. By default, fills it with appropriately constrained symbolic data, but makes no attempt to make sure that the value can make sense semantically, e.g. feb 31 can be represented.

...unless the USE_SYSTEM_TIMES state option is present, in which case it will use the system time.

https://msdn.microsoft.com/en-us/library/windows/desktop/ms724950(v=vs.85).aspx

**fill_symbolic**()

Fill the class with constrained symbolic values.

**fill_from_timestamp**(*ts*)

Fill the class with the appropriate values extracted from the given timestamp.

**Parameters**
**ts** – A POSIX timestamp.

**class** angr.procedures.win32.sim_time.**QueryPerformanceCounter**

Bases: *SimProcedure*

**class** angr.procedures.win32.sim_time.**GetTickCount**

Bases: *SimProcedure*

**class** angr.procedures.win32.sim_time.**GetTickCount64**

Bases: *SimProcedure*

## 10.30 angr.project

angr.project.**load_shellcode**(*shellcode*, *arch*, *start_offset=0*, *load_address=0*, *thumb=False*, ***kwargs*)

Load a new project based on a snippet of assembly or bytecode.

**Parameters**

- **shellcode** (bytes | str) – The data to load, as either a bytestring of instructions or a string of assembly text
- **arch** – The name of the arch to use, or an archinfo class
- **start_offset** – The offset into the data to start analysis (default 0)
- **load_address** – The address to place the data in memory (default 0)
- **thumb** – Whether this is ARM Thumb shellcode

class angr.project.**Project**

Bases: object

This is the main class of the angr module. It is meant to contain a set of binaries and the relationships between them, and perform analyses on them.

**Parameters**

- **thing** – The path to the main executable object to analyze, or a CLE Loader object.
- **default_analysis_mode** – The mode of analysis to use by default. Defaults to 'symbolic'.
- **ignore_functions** – A list of function names that, when imported from shared libraries, should never be stepped into in analysis (calls will return an unconstrained value).
- **use_sim_procedures** – Whether to replace resolved dependencies for which simprocedures are available with said simprocedures.
- **exclude_sim_procedures_func** – A function that, when passed a function name, returns whether or not to wrap it with a simprocedure.
- **exclude_sim_procedures_list** – A list of functions to *not* wrap with simprocedures.
- **arch** – The target architecture (auto-detected otherwise).
- **simos** – a SimOS class to use for this project.
- **engine** – The SimEngine class to use for this project.
- **translation_cache** (*bool*) – If True, cache translated basic blocks rather than retranslating them.
- **selfmodifying_code** (bool) – Whether we aggressively support self-modifying code. When enabled, emulation will try to read code from the current state instead of the original memory, regardless of the current memory protections.
- **store_function** – A function that defines how the Project should be stored. Default to pickling.

- **load_function** – A function that defines how the Project should be loaded. Default to unpickling.
- **analyses_preset** (*angr.misc.PluginPreset*) – The plugin preset for the analyses provider (i.e. Analyses instance).

Any additional keyword arguments passed will be passed onto `cle.Loader`.

**Variables**

- **analyses** – The available analyses.
- **entry** – The program entrypoint.
- **factory** – Provides access to important analysis elements such as path groups and symbolic execution results.
- **filename** – The filename of the executable.
- **loader** – The program loader.
- **storage** – Dictionary of things that should be loaded/stored with the Project.

**__init__**(*thing*, *default_analysis_mode=None*, *ignore_functions=None*, *use_sim_procedures=True*, *exclude_sim_procedures_func=None*, *exclude_sim_procedures_list=()*, *arch=None*, *simos=None*, *engine=None*, *load_options=None*, *translation_cache=True*, *selfmodifying_code=False*, *support_selfmodifying_code=None*, *store_function=None*, *load_function=None*, *analyses_preset=None*, *eager_ifunc_resolution=None*, *cache_limits=None*, *rustc_version=None*, *rustc_optimization_level=None*, ***kwargs*)

**Parameters**

- **load_options** (*dict[str, Any] | None*)
- **selfmodifying_code** (*bool*)
- **support_selfmodifying_code** (*bool | None*)
- **cache_limits** (*dict[str, int | None] | None*)

**arch:** *Arch*

**property llm_client**

The LLM client for this project. Lazy-initialized from environment variables on first access. Set manually via `project.llm_client = LLMClient(...)` or configure via environment variables `ANGR_LLM_MODEL`, `ANGR_LLM_API_KEY`, `ANGR_LLM_API_BASE`.

**property kb**

**get_kb**(*name*)

**property analyses:** *AnalysesHubWithDefault*

**hook**(*addr*, *hook=None*, *length=0*, *kwargs=None*, *replace=False*)

Hook a section of code with a custom function. This is used internally to provide symbolic summaries of library functions, and can be used to instrument execution or to modify control flow.

When hook is not specified, it returns a function decorator that allows easy hooking. Usage:

```
# Assuming proj is an instance of angr.Project, we will add a custom hook at␣
↪the entry
# point of the project.
@proj.hook(proj.entry)
```

(continues on next page)

(continued from previous page)

```
def my_hook(state):
    print("Welcome to execution!")
```

**Parameters**

- **addr** – The address to hook.
- **hook** – A `angr.project.Hook` describing a procedure to run at the given address. You may also pass in a SimProcedure class or a function directly and it will be wrapped in a Hook object for you.
- **length** – If you provide a function for the hook, this is the number of bytes that will be skipped by executing the hook by default.
- **kwargs** – If you provide a SimProcedure for the hook, these are the keyword arguments that will be passed to the procedure's *run* method eventually.
- **replace** (`bool` | `None`) – Control the behavior on finding that the address is already hooked. If true, silently replace the hook. If false (default), warn and do not replace the hook. If none, warn and replace the hook.

**is_hooked**(*addr*)

Returns True if *addr* is hooked.

**Parameters**
**addr** – An address.

**Return type**
`bool`

**Returns**
True if addr is hooked, False otherwise.

**hooked_by**(*addr*)

Returns the current hook for *addr*.

**Parameters**
**addr** – An address.

**Return type**
*SimProcedure* | `None`

**Returns**
None if the address is not hooked.

**unhook**(*addr*)

Remove a hook.

**Parameters**
**addr** – The address of the hook.

**hook_symbol**(*symbol_name*, *simproc*, *kwargs=None*, *replace=None*)

Resolve a dependency in a binary. Looks up the address of the given symbol, and then hooks that address. If the symbol was not available in the loaded libraries, this address may be provided by the CLE externs object.

Additionally, if instead of a symbol name you provide an address, some secret functionality will kick in and you will probably just hook that address, UNLESS you're on powerpc64 ABIv1 or some yet-unknown

scary ABI that has its function pointers point to something other than the actual functions, in which case it'll do the right thing.

**Parameters**

- **symbol_name** – The name of the dependency to resolve.
- **simproc** – The SimProcedure instance (or function) with which to hook the symbol
- **kwargs** – If you provide a SimProcedure for the hook, these are the keyword arguments that will be passed to the procedure's *run* method eventually.
- **replace** (bool | None) – Control the behavior on finding that the address is already hooked. If true, silently replace the hook. If false, warn and do not replace the hook. If none (default), warn and replace the hook.

**Returns**
The address of the new symbol.

**Return type**
int

**symbol_hooked_by**(*symbol_name*)

Return the SimProcedure, if it exists, for the given symbol name.

**Parameters**
**symbol_name** (*str*) – Name of the symbol.

**Return type**
*SimProcedure* | None

**Returns**
None if the address is not hooked.

**is_symbol_hooked**(*symbol_name*)

Check if a symbol is already hooked.

**Parameters**
**symbol_name** (*str*) – Name of the symbol.

**Returns**
True if the symbol can be resolved and is hooked, False otherwise.

**Return type**
bool

**unhook_symbol**(*symbol_name*)

Remove the hook on a symbol. This function will fail if the symbol is provided by the extern object, as that would result in a state where analysis would be unable to cope with a call to this symbol.

**rehook_symbol**(*new_address*, *symbol_name*, *stubs_on_sync*)

Move the hook for a symbol to a specific address :type new_address: :param new_address: the new address that will trigger the SimProc execution :type symbol_name: :param symbol_name: the name of the symbol (f.i. strcmp ) :return: None

**execute**(**args*, ***kwargs*)

This function is a symbolic execution helper in the simple style supported by triton and manticore. It designed to be run after setting up hooks (see Project.hook), in which the symbolic state can be checked.

This function can be run in three different ways:

- When run with no parameters, this function begins symbolic execution from the entrypoint.

- It can also be run with a "state" parameter specifying a SimState to begin symbolic execution from.
- Finally, it can accept any arbitrary keyword arguments, which are all passed to project.factory.full_init_state.

If symbolic execution finishes, this function returns the resulting simulation manager.

**terminate_execution**()

Terminates a symbolic execution that was started with Project.execute().

**pcode_block_lifter**(*arch*)

Get the p-code basic block lifter, and therefore the Sleigh context, this project decodes *arch* with.

Sleigh records context variables per address, so the blocks of one binary decode with one context and no block of another binary touches it. *arch* is normally this project's own; a *Block* may name another, and decoding that with this project's context would answer for the wrong architecture, so it gets its own.

**Return type**
*PcodeBasicBlockLifter*

**Parameters**
**arch** (*Arch*)

**languages**()

**Return type**
list[str]

**property language_confidence: str | None**

How sure LanguageDetector is about *languages()* ("high", "medium" or "low"), or None when the language did not come from detection.

**property language_is_certain: bool**

Whether the detected language is solid enough to base language-specific ABI decisions on. A single matching symbol name is enough for LanguageDetector to report a language, but not enough to reinterpret every argument and return value in the binary.

**property is_rust_binary: bool**

Whether the main binary was identified as Rust with enough confidence to enable Rust-specific analyses.

**property is_go_binary: bool**

Whether the main binary was confidently identified as Go. Go's ABI differs from the platform default in every argument and return value, so a low-confidence detection is deliberately not enough.

**property go_version_range: *GoVersionRange* | None**

The (oldest, newest) Go releases the main binary may have been built with; see *angr.go.utils.version.go_version_range()*.

**property goos: str | None**

The main binary's GOOS, when its container format tells.

**get_function_cache_limit**()

Get the cache limit for function-level caches.

**Return type**
int | None

**Returns**
The cache limit, or None for disabling the cache.

**get_cfg_node_cache_limit**()

Get the cache limit for CFG node caches.

**Return type**
int | None

**Returns**
The cache limit, or None to disable the cache.

**executable_bytes**()

The number of bytes of executable code in the main object (sections, else segments, else the whole object).

**Return type**
int

**get_cfg_segment_budget**()

Byte budget for resident CFG graph segments (cache_limits key `cfg_segment_bytes`); a graph with a budget is paged to the RuntimeDb from the start. None keeps the graph fully resident. By default only binaries with more than CFG_PAGED_EXECUTABLE_BYTES of executable code are paged.

**Return type**
int | None

## 10.32 angr.rust

### Submodules

*analyses*
*knowledge_plugins*
*mixins*
*optimization_passes*
*sim_type*
*structuring*
*typehoon*
*utils*

### 10.32.1 angr.rust.analyses

#### Submodules

| |
|---|
| *cleanup_function_identification* |
| *flirt_sig_propagation* |
| *rust_calling_convention* |
| *rust_symbol_recovery* |
| *rust_type_hints* |
| *rustc_version_identification* |
| *struct_builder* |
| *type_db_loader* |

#### angr.rust.analyses.cleanup_function_identification

**class** angr.rust.analyses.cleanup_function_identification.**CleanupFunctionIdentification**

Bases: *Analysis*

Identify cleanup functions (deallocators, drop glue, etc.) in Rust binaries.

**__init__**()

#### angr.rust.analyses.flirt_sig_propagation

**class** angr.rust.analyses.flirt_sig_propagation.**FlirtSigPropagation**

Bases: *Analysis*

Propagate FLIRT signatures through simple wrapper functions.

**__init__**(*cfg*)

#### angr.rust.analyses.rust_calling_convention

**class** angr.rust.analyses.rust_calling_convention.**Pathfinder**

Bases: object

Find paths through the CFG that satisfy certain constraints.

**__init__**(*graph*, *srda_mixin=None*)

**Parameters**
**srda_mixin** (SRDAMixin | *None*)

**find_ret2arg0_paths**(*remove_phi=False*)

**static path_to_graph**(*path*)

**find_backward_path**(*block*, *max_length=None*)

**find_forward_path**(*block*, *max_length=None*)

**class** angr.rust.analyses.rust_calling_convention.**RustCallingConventionAnalysis**

Bases: *Analysis*

Infer function prototype including struct return type and struct argument types.

Function prototype is inferred based on collected facts from the callee function body and the caller function body.

**Facts collected from callee:**

1. Memory writes to the first argument
2. Memory reads to all arguments

**Facts collected from caller:**

1. Initialization of function arguments at callsite (memory writes at callsite)
2. Uses of return value after callee is called

**__init__**(*func*, *, *ail_manager*, *callsite_path=None*, *post_callsite_path=None*, *is_call_expr=None*, *depth=0*, *max_depth=8*, *callsite_discriminant_hint=None*)

**Parameters**
**ail_manager** (*Manager*)

**property prototype**

**class** angr.rust.analyses.rust_calling_convention.**RustCallingConventionModel**

Bases: object

Stores inferred calling convention facts for a Rust function.

**__init__**()

## Submodules

*fact_collector*
*pathfinder*
*rust_calling_convention*
*rust_calling_convention_model*

### angr.rust.analyses.rust_calling_convention.fact_collector

**class** angr.rust.analyses.rust_calling_convention.fact_collector.**MemoryWriteCollector**

Bases: *AILBlockViewer*

Walk ret2arg0 paths and collect direct memory writes (Store statements) to parameter-backed addresses.

**__init__**(*fc*)

**Parameters**
**fc** (FactCollector)

**collect**()

**class** angr.rust.analyses.rust_calling_convention.fact_collector.**CalleeWriteCollector**

Bases: object

Visit all calls in the function graph. When a call forwards the current function's arg0 to a callee, recursively analyze the callee and merge its memory writes into the current function's facts.

**__init__**(*fc*)

**Parameters**
**fc** (FactCollector)

**collect**()

class angr.rust.analyses.rust_calling_convention.fact_collector.**ConstRetValueCollector**

Bases: object

Iterate over return blocks and collect constant return values, including values propagated through tail calls.

**__init__**(*fc*)

**Parameters**
**fc** (FactCollector)

**collect**()

class angr.rust.analyses.rust_calling_convention.fact_collector.**CallsiteFactCollector**

Bases: object

From the *caller* context (callsite_path), collect memory writes to stack regions that initialize struct arguments passed by reference.

**__init__**(*fc*)

**Parameters**
**fc** (FactCollector)

**collect**()

class angr.rust.analyses.rust_calling_convention.fact_collector.**FactCollector**

Bases: *CFAMixin*, *SRDAMixin*, *DFAMixin*

Orchestrator that runs all sub-collectors and exposes the combined results.

Sub-collectors write back to this object's fields; when collection is done, the results are flushed to the model.

**__init__**(*analysis*)

**collect**()

Run all sub-collectors, then flush results to the model.

### angr.rust.analyses.rust_calling_convention.pathfinder

class angr.rust.analyses.rust_calling_convention.pathfinder.**Pathfinder**

Bases: object

Find paths through the CFG that satisfy certain constraints.

**__init__**(*graph*, *srda_mixin=None*)

**Parameters**
**srda_mixin** (SRDAMixin | *None*)

**find_ret2arg0_paths**(*remove_phi=False*)

**static path_to_graph**(*path*)

**find_backward_path**(*block*, *max_length=None*)

**find_forward_path**(*block*, *max_length=None*)

### angr.rust.analyses.rust_calling_convention.rust_calling_convention

**class** angr.rust.analyses.rust_calling_convention.rust_calling_convention.**RustCallingConventionAnalysis**

Bases: *Analysis*

Infer function prototype including struct return type and struct argument types.

Function prototype is inferred based on collected facts from the callee function body and the caller function body.

**Facts collected from callee:**

1. Memory writes to the first argument
2. Memory reads to all arguments

**Facts collected from caller:**

1. Initialization of function arguments at callsite (memory writes at callsite)
2. Uses of return value after callee is called

**__init__**(*func*, ***, *ail_manager*, *callsite_path=None*, *post_callsite_path=None*, *is_call_expr=None*, *depth=0*, *max_depth=8*, *callsite_discriminant_hint=None*)

**Parameters**
**ail_manager** (*Manager*)

**property prototype**

### angr.rust.analyses.rust_calling_convention.rust_calling_convention_model

**class** angr.rust.analyses.rust_calling_convention.rust_calling_convention_model.**RustCallingConventionModel**

Bases: object

Stores inferred calling convention facts for a Rust function.

**__init__**()

### angr.rust.analyses.rust_symbol_recovery

**class** angr.rust.analyses.rust_symbol_recovery.**RustSymbolRecovery**

Bases: *Analysis*

This analysis recovers Rust symbols by analyzing the binary's symbol table and debug information. It identifies Rust-specific symbols, such as those related to traits, generics, and async functions, and annotates them for further analysis.

**OPT_LEVELS = ['0', '1', '2', '3']**

**__init__**(*sig_dirs=None*)

### angr.rust.analyses.rust_type_hints

**class** angr.rust.analyses.rust_type_hints.**RustTypeHintsAnalysis**

Bases: *Analysis*

Collect type hints from Rust-specific patterns in the AIL graph.

**__init__**(*func*, *graph*, *variable_map=None*)

#### angr.rust.analyses.rustc_version_identification

**class** angr.rust.analyses.rustc_version_identification.**RustcVersionIdentification**

Bases: *Analysis*

Identify the rustc version used to compile a Rust binary by matching FLIRT signatures across known rustc versions and selecting the version with the highest match count.

**OPT_LEVELS = ['0', '1', '2', '3']**

**__init__**(*sig_dirs=None*)

#### angr.rust.analyses.struct_builder

**class** angr.rust.analyses.struct_builder.**StructBuilder**

Bases: *Analysis*

Build Rust struct types from memory write patterns.

**__init__**(*context*, *strict=False*)

**Parameters**
**context** (OptimizationPass)

**build**(*field_exprs*, *struct_ty*)

**Return type**
*Struct* | *Array* | None

#### angr.rust.analyses.type_db_loader

**class** angr.rust.analyses.type_db_loader.**TypeDBLoader**

Bases: *Analysis*

Load Rust type definitions from a version-specific JSON type database.

**__init__**()

### 10.32.2 angr.rust.knowledge_plugins

**class** angr.rust.knowledge_plugins.**ClinicFactory**

Bases: *KnowledgeBasePlugin*

Cache and provide Clinic analysis results for Rust functions.

**__init__**(*kb*)

**get**(*func*, *optimization_passes=None*, *end_stage=None*)

**class** angr.rust.knowledge_plugins.**KnownStructs**

Bases: *KnowledgeBasePlugin*

Store known Rust struct type definitions.

**__init__**(*kb*)

**get**(*item*, *default=None*)

**match_with_known_structs**(*fields*)

**Return type**
*RustSimStruct* | None

**class** angr.rust.knowledge_plugins.**Librust**

Bases: *KnowledgeBasePlugin*, *SimLibrary*

Rust standard library procedure definitions.

**__init__**(*kb*)

**class** angr.rust.knowledge_plugins.**RustCallingConventions**

Bases: *KnowledgeBasePlugin*, MutableMapping

Store inferred Rust calling conventions keyed by function address.

**__init__**(*kb*)

**copy**()

**class** angr.rust.knowledge_plugins.**TypeHints**

Bases: *KnowledgeBasePlugin*

Store type hints for virtual variables inferred from Rust patterns.

**__init__**(*kb*)

**add_type_hint**(*vvar*, *ty*, *func_addr*)

**Return type**
None

**Parameters**
**func_addr** (*int*)

**get_type_hints**(*func_addr*)

**Return type**
dict[int, *TypeConstant*]

**Parameters**
**func_addr** (*int*)

**copy**()

**Return type**
*TypeHints*

## Submodules

*clinic_factory*
*known_structs*
*librust*
*rust_calling_conventions*
*type_hints*

### angr.rust.knowledge_plugins.clinic_factory

class angr.rust.knowledge_plugins.clinic_factory.**ClinicFactory**

Bases: *KnowledgeBasePlugin*

Cache and provide Clinic analysis results for Rust functions.

**__init__**(*kb*)

**get**(*func*, *optimization_passes=None*, *end_stage=None*)

### angr.rust.knowledge_plugins.known_structs

class angr.rust.knowledge_plugins.known_structs.**StructMatcher**

Bases: object

Match memory write patterns against known Rust struct layouts.

**__init__**(*project*)

**match**(*fields*)

class angr.rust.knowledge_plugins.known_structs.**KnownStructs**

Bases: *KnowledgeBasePlugin*

Store known Rust struct type definitions.

**__init__**(*kb*)

**get**(*item*, *default=None*)

**match_with_known_structs**(*fields*)

**Return type**
*RustSimStruct* | None

### angr.rust.knowledge_plugins.librust

class angr.rust.knowledge_plugins.librust.**Librust**

Bases: *KnowledgeBasePlugin*, *SimLibrary*

Rust standard library procedure definitions.

**__init__**(*kb*)

### angr.rust.knowledge_plugins.rust_calling_conventions

class angr.rust.knowledge_plugins.rust_calling_conventions.**RustCallingConventions**

Bases: *KnowledgeBasePlugin*, MutableMapping

Store inferred Rust calling conventions keyed by function address.

**__init__**(*kb*)

**copy**()

#### angr.rust.knowledge_plugins.type_hints

**class** angr.rust.knowledge_plugins.type_hints.**TypeHints**

Bases: *KnowledgeBasePlugin*

Store type hints for virtual variables inferred from Rust patterns.

**__init__**(*kb*)

**add_type_hint**(*vvar*, *ty*, *func_addr*)

**Return type**
None

**Parameters**
**func_addr** (*int*)

**get_type_hints**(*func_addr*)

**Return type**
dict[int, *TypeConstant*]

**Parameters**
**func_addr** (*int*)

**copy**()

**Return type**
*TypeHints*

### 10.32.3 angr.rust.mixins

**class** angr.rust.mixins.**CFAMixin**

Bases: object

Control Flow Analysis Mixin

**__init__**(*graph*, *project*)

**num_predecessors**(*block*)

**get_one_predecessor**(*block*)

**Return type**
Block

**num_successors**(*block*)

**get_one_successor**(*block*)

**Return type**
Block

**static first_non_label_stmt**(*block*)

**Return type**
*Statement* | None

**static last_stmt**(*block*)

**Return type**
*Statement* | None

**static replace_stmt**(*block*, *stmts*, *replacement*)

**terminal_call**(*block*)

**Return type**
*Call* | None

**get_call_target**(*call*)

**Return type**
str | None

**Parameters**
**call** (*Call*)

**match_call**(*block_or_stmt*, *expected*, *monopolize=True*, *use_trait_name=True*)

**class** angr.rust.mixins.**CFGTransformationMixin**

Bases: object

Mixin providing CFG graph transformation operations (block removal, splitting, etc.).

**__init__**(*graph*)

**update_block_indexes**()

**remove_jump_target**(*block*, *jump_target*, *jump_target_idx*)

**Parameters**

- **block** (*Block*)
- **jump_target** (*Const | int*)
- **jump_target_idx** (*int*)

**remove_false_branch**(*block*)

**Parameters**
**block** (*Block*)

**replace_jump_target**(*block*, *old_target*, *old_target_idx*, *new_target*, *new_target_idx*)

**Parameters**

- **old_target** (*Const | int | None*)
- **old_target_idx** (*int*)
- **new_target** (*Const | int*)
- **new_target_idx** (*int*)

**remove_block**(*block*)

**Parameters**
**block** (*Block*)

**split_block**(*block*, *new_head_stmt*)

**Parameters**
**block** (*Block*)

class angr.rust.mixins.**DFAMixin**

Bases: object

Data Flow Analysis Helper

**__init__**(*graph=None*)

**collect_stack_defs_at**(*block*)

Collect stack definitions at specific block

**collect_callsite_stack_defs**(*callsite_block*, *max_blocks=1*)

Collect stack variable definitions at a given callsite

**static extract_write_to_stack_vvar**(*stmt*)

**Return type**
tuple[*VirtualVariable* | None, *Expression* | None]

**static extract_stack_data_flow**(*stmt*)

**find_reg_ptr_to_reg_data_flow**(*block*, *reg_vvar*)

**find_stack_data_flow**(*block*, *src_offset*, *size*)

**static extract_stack_to_reg_data_flow**(*stmt*)

**find_stack_to_reg_data_flow**(*block*, *src_offset*, *size*)

**get_def_block_and_stmt**(*data*)

class angr.rust.mixins.**SRDAMixin**

Bases: object

Mixin providing SSA reaching definitions analysis access.

**__init__**(*subject*, *graph*, *project*, *variable_map*)

**Parameters**
**variable_map** (VariableMap)

**get_vvar_value**(*vvar*)

**Return type**
*Expression* | None

**Parameters**
**vvar** (VirtualVariable)

**get_terminal_vvar_values**(*vvar*, *visited=None*)

**get_terminal_vvar_value**(*vvar*, *visited=None*)

**get_terminal_vvar**(*vvar*, *visited=None*)

**get_stack_vvar_by_insn**(*stack_offset*, *addr*, *block_idx=0*, *size=None*, *op_type=ObservationPointType.OP_BEFORE*)

**Return type**
*VirtualVariable* | None

**Parameters**

- **stack_offset** (*int*)

- **addr** (*int*)
- **block_idx** (*int*)

**get_stack_vvars_by_insn**(*stack_offset*, *addr*, *block_idx=0*, *size=None*, *op_type=ObservationPointType.OP_BEFORE*)

All definitions of the stack slot that reach the instruction, one per varid.

**Return type**
list[*VirtualVariable*]

**Parameters**

- **stack_offset** (*int*)
- **addr** (*int*)
- **block_idx** (*int*)

**get_stack_vvar_and_offset_by_insn**(*stack_offset*, *addr*, *block_idx=0*, *op_type=ObservationPointType.OP_BEFORE*)

**Return type**
tuple[*VirtualVariable*, int] | tuple[None, None]

**Parameters**

- **stack_offset** (*int*)
- **addr** (*int*)
- **block_idx** (*int*)

**get_vvar_type**(*vvar*)

**Return type**
*SimType* | None

**get_def_by_vvar**(*vvar*)

**class** angr.rust.mixins.**SSAVariableMixin**

Bases: object

Mixin for creating and fixing SSA stack virtual variables.

**__init__**(*context*)

**Parameters**
**context** (OptimizationPass)

**new_stack_vvar**(*dst_offset*, *bits*, *tags*, *record=True*)

**ambiguous_new_stack_vvars**()

Varids of new stack vvars that reach a use of their slot together with a pre-existing definition, i.e., the slot's earlier value is still live where the new value arrives. No phi merges them.

**Return type**
set[int]

**fix_stack_vvar_uses**()

### Submodules

cfa_mixin
cfg_transformation_mixin
dfa_mixin
srda_mixin
ssa_variable_mixin

### angr.rust.mixins.cfa_mixin

**class** angr.rust.mixins.cfa_mixin.**CFAMixin**

Bases: object

Control Flow Analysis Mixin

**__init__**(*graph*, *project*)

**num_predecessors**(*block*)

**get_one_predecessor**(*block*)

**Return type**
Block

**num_successors**(*block*)

**get_one_successor**(*block*)

**Return type**
Block

**static first_non_label_stmt**(*block*)

**Return type**
*Statement* | None

**static last_stmt**(*block*)

**Return type**
*Statement* | None

**static replace_stmt**(*block*, *stmts*, *replacement*)

**terminal_call**(*block*)

**Return type**
*Call* | None

**get_call_target**(*call*)

**Return type**
str | None

**Parameters**
**call** (Call)

**match_call**(*block_or_stmt*, *expected*, *monopolize=True*, *use_trait_name=True*)

### angr.rust.mixins.cfg_transformation_mixin

**class** angr.rust.mixins.cfg_transformation_mixin.**CFGTransformationMixin**

Bases: object

Mixin providing CFG graph transformation operations (block removal, splitting, etc.).

**__init__**(*graph*)

**update_block_indexes**()

**remove_jump_target**(*block*, *jump_target*, *jump_target_idx*)

**Parameters**

- **block** (*Block*)
- **jump_target** (Const | *int*)
- **jump_target_idx** (*int*)

**remove_false_branch**(*block*)

**Parameters**
**block** (*Block*)

**replace_jump_target**(*block*, *old_target*, *old_target_idx*, *new_target*, *new_target_idx*)

**Parameters**

- **old_target** (Const | *int* | *None*)
- **old_target_idx** (*int*)
- **new_target** (Const | *int*)
- **new_target_idx** (*int*)

**remove_block**(*block*)

**Parameters**
**block** (*Block*)

**split_block**(*block*, *new_head_stmt*)

**Parameters**
**block** (*Block*)

### angr.rust.mixins.dfa_mixin

**class** angr.rust.mixins.dfa_mixin.**DFAMixin**

Bases: object

Data Flow Analysis Helper

**__init__**(*graph=None*)

**collect_stack_defs_at**(*block*)

Collect stack definitions at specific block

**collect_callsite_stack_defs**(*callsite_block*, *max_blocks=1*)

Collect stack variable definitions at a given callsite

**static extract_write_to_stack_vvar**(*stmt*)

**Return type**
tuple[*VirtualVariable* | None, *Expression* | None]

**static extract_stack_data_flow**(*stmt*)

**find_reg_ptr_to_reg_data_flow**(*block*, *reg_vvar*)

**find_stack_data_flow**(*block*, *src_offset*, *size*)

**static extract_stack_to_reg_data_flow**(*stmt*)

**find_stack_to_reg_data_flow**(*block*, *src_offset*, *size*)

**get_def_block_and_stmt**(*data*)

### angr.rust.mixins.srda_mixin

**class** angr.rust.mixins.srda_mixin.**SRDAMixin**

Bases: object

Mixin providing SSA reaching definitions analysis access.

**__init__**(*subject*, *graph*, *project*, *variable_map*)

**Parameters**
**variable_map** (VariableMap)

**get_vvar_value**(*vvar*)

**Return type**
*Expression* | None

**Parameters**
**vvar** (VirtualVariable)

**get_terminal_vvar_values**(*vvar*, *visited=None*)

**get_terminal_vvar_value**(*vvar*, *visited=None*)

**get_terminal_vvar**(*vvar*, *visited=None*)

**get_stack_vvar_by_insn**(*stack_offset*, *addr*, *block_idx=0*, *size=None*, *op_type=ObservationPointType.OP_BEFORE*)

**Return type**
*VirtualVariable* | None

**Parameters**

- **stack_offset** (*int*)
- **addr** (*int*)
- **block_idx** (*int*)

**get_stack_vvars_by_insn**(*stack_offset*, *addr*, *block_idx=0*, *size=None*, *op_type=ObservationPointType.OP_BEFORE*)

All definitions of the stack slot that reach the instruction, one per varid.

**Return type**
list[*VirtualVariable*]

**Parameters**

- **stack_offset** (*int*)
- **addr** (*int*)
- **block_idx** (*int*)

**get_stack_vvar_and_offset_by_insn**(*stack_offset*, *addr*, *block_idx=0*, *op_type=ObservationPointType.OP_BEFORE*)

**Return type**
tuple[*VirtualVariable*, int] | tuple[None, None]

**Parameters**

- **stack_offset** (*int*)
- **addr** (*int*)
- **block_idx** (*int*)

**get_vvar_type**(*vvar*)

**Return type**
*SimType* | None

**get_def_by_vvar**(*vvar*)

### angr.rust.mixins.ssa_variable_mixin

**class** angr.rust.mixins.ssa_variable_mixin.**SSAVariableMixin**

Bases: object

Mixin for creating and fixing SSA stack virtual variables.

**__init__**(*context*)

**Parameters**
**context** (OptimizationPass)

**new_stack_vvar**(*dst_offset*, *bits*, *tags*, *record=True*)

**ambiguous_new_stack_vvars**()

Varids of new stack vvars that reach a use of their slot together with a pre-existing definition, i.e., the slot's earlier value is still live where the new value arrives. No phi merges them.

**Return type**
set[int]

**fix_stack_vvar_uses**()

### angr.rust.optimization_passes.cleanup_code_remover

**class** angr.rust.optimization_passes.cleanup_code_remover.**CleanupCodeRemover**

Bases: *OptimizationPass*, *CFGTransformationMixin*, *CFAMixin*, *SRDAMixin*

Remove cleanup code such as deallocation and drop calls.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Remove cleanup code'**

**__init__**(*func*, *manager*, ***kwargs*)

**Parameters**
**manager** (*Manager*)

### angr.rust.optimization_passes.combo_register_rewriter

**class** angr.rust.optimization_passes.combo_register_rewriter.**ComboRegisterRewriter**

Bases: *OptimizationPass*, *SRDAMixin*

Rewrite return expressions for calls to functions returning several values via multiple registers.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Rewrite return expressions for calls to functions returning several values via multiple registers'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.rust.optimization_passes.deref_coercion_simplifier

**class** angr.rust.optimization_passes.deref_coercion_simplifier.**StrCmpSimplifierWalker**

Bases: *AILBlockRewriter*

Rewrite string comparison expressions to use simplified binary ops.

**__init__**(*context*)

**Parameters**
**context** (DerefCoercionSimplifier)

**class** angr.rust.optimization_passes.deref_coercion_simplifier.**DerefCoercionSimplifier**

Bases: *OptimizationPass*, *SRDAMixin*, *CFAMixin*

Simplify explicit deref coercion operations on string arguments.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Simplify explict deref coercion operations'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.rust.optimization_passes.deref_coercion_simplifier_uninlined

**class** angr.rust.optimization_passes.deref_coercion_simplifier_uninlined.**DerefCoercionSimplifierUninlined**

Bases: *OptimizationPass*, *SRDAMixin*, *CFAMixin*, *AILBlockRewriter*

Simplify explicit deref coercion operations that have not been inlined. 1. Identify assignments where a VirtualVariable is assigned the result of a deref coercion function call. 2. Record the mapping from the VirtualVariable to the argument of the deref coercion function. 3. Traverse the AIL graph and replace occurrences of the VirtualVariable with the recorded argument. 4. Remove the original assignment statements that performed the deref coercion. 5. Update the AIL graph to reflect these changes.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 8**

**NAME = 'Simplify explicit deref coercion operations (uninlined)'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.rust.optimization_passes.error_propagation_simplifier

**class** angr.rust.optimization_passes.error_propagation_simplifier.**ErrorPropagationWalker**

Bases: *SequenceWalker*

Walk sequence nodes to detect and simplify error propagation patterns.

**__init__**(*context*)

**Parameters**
**context** (ErrorPropagationSimplifier)

**class** angr.rust.optimization_passes.error_propagation_simplifier.**ErrorPropagationSimplifier**

Bases: *SequenceOptimizationPass*

Recover the Rust error propagation '?' operator in decompiled output.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 11**

**NAME = 'Recover error propagation "?" operator'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.rust.optimization_passes.function_prototype_inference

**class** angr.rust.optimization_passes.function_prototype_inference.**FunctionPrototypeInference**

Bases: *OptimizationPass*, *CFAMixin*, *SSAVariableMixin*

Infer potential struct/enum argument types and return types for function calls.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Infer potential struct/enum argument types and return types'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.rust.optimization_passes.macro

### Submodules

| | |
|---|---|
| *fmt_template* | Decoder for the `core::fmt::Arguments` template byte encoding introduced in rustc 1.93. |
| *format_macro_simplifier* | |

### angr.rust.optimization_passes.macro.fmt_template

Decoder for the `core::fmt::Arguments` template byte encoding introduced in rustc 1.93.

See the comment on `struct Arguments` in library/core/src/fmt/mod.rs.

**class** angr.rust.optimization_passes.macro.fmt_template.**Placeholder**

Bases: object

One `{...}` in a format template.

**arg_index:** *int*

**flags:** *int* = **1610612768**

**width:** *int* | *None* = **None**

**precision:** *int* | *None* = **None**

**width_indirect:** *bool* = **False**

**precision_indirect:** *bool* = **False**

**spec**(*trait*)

Render the part after `:` (without the `:`). `trait` is "", "?", "x", "X", "o", "b", "e", "E", "p".

**Return type**
str

**Parameters**
**trait** (*str*)

**__init__**(*arg_index*, *flags=1610612768*, *width=None*, *precision=None*, *width_indirect=False*, *precision_indirect=False*)

**Parameters**

- **arg_index** (*int*)
- **flags** (*int*)
- **width** (*int | None*)
- **precision** (*int | None*)
- **width_indirect** (*bool*)
- **precision_indirect** (*bool*)

**Return type**
None

angr.rust.optimization_passes.macro.fmt_template.**decode_template**(*read*, *addr*)

Decode a template at `addr`. `read(addr, size)` returns the bytes or None when unreadable. Returns the list of literal pieces and placeholders, or None if the bytes are not a valid template.

**Return type**
list[str | *Placeholder*] | None

**Parameters**

- **read** (*Callable[[int, int], bytes | None]*)
- **addr** (*int*)

angr.rust.optimization_passes.macro.fmt_template.**num_args**(*pieces*)

The number of `rt::Argument` entries a template refers to.

**Return type**
`int`

**Parameters**
**pieces** (*list[str | Placeholder]*)

### angr.rust.optimization_passes.macro.format_macro_simplifier

**class** angr.rust.optimization_passes.macro.format_macro_simplifier.**FormatWrapperIdentification**

Bases: *Analysis*

Identify functions that wrap format/print operations.

**__init__**()

**property format_wrappers**

**class** angr.rust.optimization_passes.macro.format_macro_simplifier.**FormatWrappers**

Bases: *KnowledgeBasePlugin*

Knowledge base plugin for resolving format wrapper functions.

**__init__**(*kb*)

**resolve**(*addr*)

**class** angr.rust.optimization_passes.macro.format_macro_simplifier.**FormatMacroSimplifier**

Bases: *OptimizationPass*, *CFAMixin*, *DFAMixin*, *SRDAMixin*, *SSAVariableMixin*

Recover print-like macros from format argument construction patterns.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Recover print-like macros'**

**__init__**(*func*, *manager*, ***kwargs*)

**replace_call**(*call*, *_block*, *_stmt*)

**Parameters**
- **call** (*Call*)
- **_block** (*Block*)

### angr.rust.optimization_passes.outliners

### Submodules

*string_cmp_outliner*
*string_literal_outliner*

continues on next page

Table 111 – continued from previous page

| |
|---|
| *string_outliner* |

| *vec_outliner* |

### angr.rust.optimization_passes.outliners.string_cmp_outliner

**class** angr.rust.optimization_passes.outliners.string_cmp_outliner.**StringCmpOutliner**

Bases: *OptimizationPass*

Outline string comparison operations into simplified expressions.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Outline string comparisons'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.rust.optimization_passes.outliners.string_literal_outliner

**class**
angr.rust.optimization_passes.outliners.string_literal_outliner.**StringLiteralOutliner**

Bases: *OptimizationPass*, *DFAMixin*, *SSAVariableMixin*

Replace string literal construction patterns with StringLiteral expressions.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Outline struct fields to string literals'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.rust.optimization_passes.outliners.string_outliner

**class** angr.rust.optimization_passes.outliners.string_outliner.**StringOutliner**

Bases: *OptimizationPass*

Outline String::from and to_string patterns into StringLiteral expressions.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Outline String structs to `String::new`'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.rust.optimization_passes.outliners.unwrap_outliner

**class** angr.rust.optimization_passes.outliners.unwrap_outliner.**UnwrapSimplifierState**

Bases: object

State for tracking unwrap pattern detection.

**__init__**(*conditional_jump_block*, *unwrap_failed_block*, *ownership_move_block*, *cmp_expr*, *unwrap_failed_func_name*)

**class** angr.rust.optimization_passes.outliners.unwrap_outliner.**UnwrapOutliner**

Bases: *OptimizationPass*, *CFAMixin*, *SRDAMixin*, *DFAMixin*, *CFGTransformationMixin*, *SSAVariableMixin*

Replace unwrap/expect patterns with simplified function call expressions.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Outline unwrap function calls'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.rust.optimization_passes.outliners.vec_outliner

**class** angr.rust.optimization_passes.outliners.vec_outliner.**VecOutliner**

Bases: *OptimizationPass*

Replace Vec construction patterns with vec! macro expressions.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Outline Vec structs to `Vec::new`'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.rust.optimization_passes.pattern_match_simplifier

**class** angr.rust.optimization_passes.pattern_match_simplifier.**PatternMatchWalker**

Bases: *SequenceWalker*, *DFAMixin*

Walker that converts condition nodes into pattern match or if-let nodes.

**__init__**(*var_manager*, *graph*, *variable_map*, *vvar_defs=None*)

**Parameters**
**vvar_defs** (*dict[int, Expression] | None*)

**class** angr.rust.optimization_passes.pattern_match_simplifier.**PatternMatchSimplifier**

Bases: *SequenceOptimizationPass*

Recover idiomatic Rust pattern match constructs from condition nodes.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 11**

**NAME = 'Recover idiomatic Rust error handling code'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.rust.optimization_passes.pre_pattern_match_simplifier

**class**
angr.rust.optimization_passes.pre_pattern_match_simplifier.**PrePatternMatchSimplifier**

Bases: *OptimizationPass*, *ReturnDuplicatorBase*, *DFAMixin*

Duplicate return blocks for identified pattern matches to form if-else structures. For example the following code:

```
if (...){
    ...
} else {
    v6 = std::fs::File::open(a1, a2);
    if !v6 as i32 {
        ...
    }
}
return Err(struct8 {
    field_0: v11
});
```

should be converted to:

```
v6 = std::fs::File::open(a1, a2);
if v6 as i32 {
    return Err(struct8 {
        field_0: v11
    });
} else {
    ...
}
```

for recovering pattern match constructs in later stage

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Duplicate return blocks to prepare for pattern match simplification'**

**DESCRIPTION = '\n Duplicate return blocks for identified pattern matches to form if-else structures.\n For example the following code::\n\n if (...){\n ...\n } else {\n v6 = std::fs::File::open(a1, a2);\n if !v6 as i32 {\n ...\n }\n }\n return Err(struct8 {\n field_0:  v11\n });\n\n should be converted to::\n\n v6 = std::fs::File::open(a1, a2);\n if v6 as i32 {\n return Err(struct8 {\n field_0: v11\n });\n } else {\n ...\n }\n\n for recovering pattern match constructs in later stage\n '**

**STRUCTURING**: list[str] | None = ['sailr', 'dream']

**__init__**(*func*, *manager*, *, *vvar_id_start*, *max_calls_in_regions=2*, *minimize_copies_for_regions=True*, *scratch=None*, ***kwargs*)

**Parameters**

- **vvar_id_start** (*int*)
- **max_calls_in_regions** (*int*)
- **minimize_copies_for_regions** (*bool*)
- **scratch** (*dict[str, Any] | None*)

**static extract_scrutinee_and_discriminant**(*condition*)

**static inverse_variant**(*enum_type*, *discriminant*)

**Return type**
*EnumVariant* | None

### angr.rust.optimization_passes.redundant_block_remover

**class** angr.rust.optimization_passes.redundant_block_remover.**RedundantBlockRemover**

Bases: *OptimizationPass*, *CFAMixin*, *CFGTransformationMixin*

Remove redundant blocks that have no effect on functionality.

**ARCHES = None**

**PLATFORMS = None**

**STAGE**: *OptimizationPassStage* = 9

**NAME = 'Remove redundant blocks that have no effect on functionality'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.rust.optimization_passes.ret_expr_rewriter

**class** angr.rust.optimization_passes.ret_expr_rewriter.**RetExprRewriter**

Bases: *OptimizationPass*

Rewrite return expressions for calls to functions returning several values via multiple registers.

**ARCHES = None**

**PLATFORMS = None**

**STAGE**: *OptimizationPassStage* = 1

**NAME = 'Rewrite return expressions for calls to functions returning several values via multiple registers'**

**FLAVOR = 'rust'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.rust.optimization_passes.rust_calling_convention

class angr.rust.optimization_passes.rust_calling_convention.**RustCallingConvention**

Bases: *OptimizationPass*

Apply Rust calling convention analysis results to function prototypes.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 1**

**NAME = 'Recover Rust prototypes and calling convention for current function'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.rust.optimization_passes.security_check_remover

class angr.rust.optimization_passes.security_check_remover.**SecurityCheckRemover**

Bases: *OptimizationPass*, *CFAMixin*, *CFGTransformationMixin*

Remove Rust bounds-check and overflow-check panic branches.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Remove security check'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.rust.optimization_passes.str_argument_simplifier

class angr.rust.optimization_passes.str_argument_simplifier.**StrArgumentSimplifier**

Bases: *OptimizationPass*, *SRDAMixin*

Simplify string literals used as function call arguments in Rust binaries.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 8**

**NAME = 'Simplify string literals used as function call arguments'**

**__init__**(*func*, *manager*, ***kwargs*)

**try_str_literal**(*arg0*, *arg1*)

**try_str_reference**(*arg0*, *arg1*)

Try to identify a &str reference from two arguments. For example, given the following call:

```
Call (
    target: 0x4696a0<64>, prototype: ...,
    args: [
        (Reference vvar_400{stack -848}),
        Load(addr=(Reference vvar_300{combo_reg (16, 32)}), size=8,␣
↪endness=Iend_LE),
        Load(addr=((Reference vvar_300{combo_reg (16, 32)}) + 0x8<64>), size=8,␣
↪endness=Iend_LE),
        Load(addr=(Reference vvar_307{combo_reg (16, 32)}), size=8,␣
↪endness=Iend_LE),
        Load(addr=((Reference vvar_307{combo_reg (16, 32)}) + 0x8<64>), size=8,␣
↪endness=Iend_LE)
    ]
)
```

We can identify that the second and third arguments form a &str reference.

**replace_call**(*call*, *_block*, *_stmt*)

**Parameters**

- **call** (Call)
- **_block** (*Block*)

### angr.rust.optimization_passes.struct_instantiation_simplifier

**class** angr.rust.optimization_passes.struct_instantiation_simplifier.**StructBuilder**

Bases: object

Build Struct expressions from sequential memory write patterns.

**__init__**(*context*)

**Parameters**
**context** (StructInstantiationSimplifier)

**build**(*field_exprs*, *struct_ty*)

**Return type**
*Struct* | *Array* | None

**class** angr.rust.optimization_passes.struct_instantiation_simplifier.**StructInstantiationSimplifier**

Bases: *OptimizationPass*, *SRDAMixin*, *CFAMixin*, *DFAMixin*, *SSAVariableMixin*

Simplify struct instantiation from sequential stack writes into Struct expressions.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Make callsite based on known/recovered prototypes'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.rust.optimization_passes.struct_return_simplifier

class angr.rust.optimization_passes.struct_return_simplifier.**StructReturnSimplifier**

Bases: *OptimizationPass*, *SRDAMixin*, *CFGTransformationMixin*

Simplify struct return patterns by wrapping return values in enum constructors.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Simplify function return sites'**

**__init__**(*func*, *manager*, ***kwargs*)

**get_existing_vvar**(*fields*, *block*)

**try_convert_to_enum**(*struct*)

**Parameters**
**struct** (Struct)

**collect_ret_expr**(*path*)

### angr.rust.optimization_passes.utils

class angr.rust.optimization_passes.utils.**CallRewriter**

Bases: *AILBlockRewriter*

Rewrite Call expressions and SideEffectStatements via a callback.

**__init__**(*callback*)

class angr.rust.optimization_passes.utils.**SideEffectStatementRewriter**

Bases: *AILBlockRewriter*

Rewrite SideEffectStatement nodes via a callback.

**__init__**(*callback*)

angr.rust.optimization_passes.utils.**extract_callee**(*obj*, *kb*)

angr.rust.optimization_passes.utils.**extract_str**(*project*, *str_ptr*, *str_len*)

Extract Rust string literal with given ptr and len

angr.rust.optimization_passes.utils.**extract_str_from_addr**(*project*, *addr*)

angr.rust.optimization_passes.utils.**replace_argument_pairs**(*call*, *callback*)

**Return type**
*Call*

**Parameters**
**call** (Call)

### 10.32.5 angr.rust.sim_type

angr.rust.sim_type.**is_composite_type**(*ty*)

**class** angr.rust.sim_type.**RustSimType**

Bases: *SimType*

**repr**(*name=None*, *full=0*, *memo=None*, *indent=0*)

**Parameters**
**indent** (*int | None*)

**c_repr**(*name=None*, *full=0*, *memo=None*, *indent=0*, *name_parens=True*, ***kwargs*)

**Parameters**

- **indent** (*int | None*)
- **name_parens** (*bool*)

**class** angr.rust.sim_type.**RustSimTypeInt**

Bases: *RustSimType*, *SimTypeInt*

**copy**()

**repr**(*name=None*, *full=0*, *memo=None*, *indent=0*)

**Parameters**
**indent** (*int | None*)

**property alignment**

The alignment of the type in bytes.

**property size: int**

The size of the type in bits, or None if no size is computable.

**class** angr.rust.sim_type.**RustSimTypeSize**

Bases: *RustSimTypeInt*

**property size**

The size of the type in bits, or None if no size is computable.

**copy**()

**class** angr.rust.sim_type.**RustSimTypeFunction**

Bases: *RustSimType*, *SimTypeFunction*

SimTypeFunction is a type that specifies an actual function (i.e. not a pointer) with certain types of arguments and a certain return value.

**args: list[*RustSimType*]**

**returnty: *RustSimType* | None**

**base: bool = False**

**__init__**(*args*, *returnty*, *label=None*, *arg_names=None*, *variadic=False*, *is_arg0_retbuf=False*, *is_class_member_function=False*)

**Parameters**

- **label** – The type label

- **args** (list[*RustSimType*]) – A tuple of types representing the arguments to the function
- **returnty** (*RustSimType* | None) – The return type of the function, or none for void
- **variadic** – Whether the function accepts varargs

**property size**

The size of the type in bits, or None if no size is computable.

**repr**(*name=None*, *full=0*, *memo=None*, *indent=0*)

**Parameters**
**indent** (*int | None*)

**normalize**()

**copy**()

**class** angr.rust.sim_type.**RustSimTypeReference**

Bases: *RustSimType*, *SimTypePointer*

SimTypePointer is a type that specifies a pointer to some other type.

**__init__**(*pts_to*, *label=None*, *offset=0*)

**Parameters**

- **label** – The type label.
- **pts_to** – The type to which this pointer points.

**repr**(*name=None*, *full=0*, *memo=None*, *indent=0*)

**Parameters**
**indent** (*int | None*)

**property size**

The size of the type in bits, or None if no size is computable.

**copy**()

**class** angr.rust.sim_type.**RustSimTypeArray**

Bases: *RustSimType*, *SimTypeArray*

SimTypeArray is a type that specifies a series of data laid out in sequence.

**__init__**(*elem_type*, *length=None*, *label=None*)

**Parameters**

- **label** – The type label.
- **elem_type** – The type of each element in the array.
- **length** – An expression of the length of the array, if known.

**repr**(*name=None*, *full=0*, *memo=None*, *indent=0*)

**Parameters**
**indent** (*int | None*)

**copy**()

**property size**

The size of the type in bits, or None if no size is computable.

**class** angr.rust.sim_type.**RustSimStruct**

Bases: *RustSimType*, *SimStruct*

**property size: int**

The size of the type in bits, or None if no size is computable.

**repr**(*name=None*, *full=0*, *memo=None*, *indent=0*)

**Parameters**
**indent** (*int | None*)

**copy**()

**get_field_ty**(*name*)

**get_field_offset**(*name*, *default=None*)

**class** angr.rust.sim_type.**RustSimTypeNumOffset**

Bases: *RustSimType*, *SimTypeNumOffset*

like SimTypeNum, but supports an offset of 1 to 7 to a byte aligned address to allow structs with bitfields

**repr**(*name=None*, *full=0*, *memo=None*, *indent=0*)

**Parameters**
**indent** (*int | None*)

**class** angr.rust.sim_type.**RustSimTypeSlice**

Bases: *RustSimStruct*, *SimType*

**repr**(*name=None*, *full=0*, *memo=None*, *indent=0*)

**Parameters**
**indent** (*int | None*)

**copy**()

**property size**

The size of the type in bits, or None if no size is computable.

**class** angr.rust.sim_type.**RustSimTypeVec**

Bases: *RustSimStruct*, *SimType*

**repr**(*name=None*, *full=0*, *memo=None*, *indent=0*)

**Parameters**
**indent** (*int | None*)

**class** angr.rust.sim_type.**RustSimTypeBottom**

Bases: *RustSimType*, *SimTypeBottom*

**property size: int**

The size of the type in bits, or None if no size is computable.

**repr**(*name=None*, *full=0*, *memo=None*, *indent=0*)

**Parameters**
**indent** (*int | None*)

class angr.rust.sim_type.**EnumVariant**

Bases: object

**__init__**(*name*, *fields*, *discriminant*, *discriminant_size*)

**fields:** list[tuple[*SimType*, str | None]]

**static from_no_data**(*name*, *discriminant*, *discriminant_size*)

**static from_single_field_ty**(*name*, *field_ty*, *discriminant*, *discriminant_size*)

**has_fields**()

**property first_field_offset**

**property field_offsets**

**property bits**

**property size**

**property type**

**as_struct_ty**()

**with_arch**(*arch*, *memo=None*)

**Parameters**
**memo** (*dict[str, SimType] | None*)

**to_json**(*memo=None*)

**static from_json**(*d*, *type_collection=None*, *memo=None*, *decoded=None*)

class angr.rust.sim_type.**RustSimEnum**

Bases: *RustSimType*, *SimType*

**property size:** int

The size of the type in bits, or None if no size is computable.

**copy**()

**repr**(*name=None*, *full=0*, *memo=None*, *indent=0*)

**Parameters**
**indent** (*int | None*)

**get_variant**(*discriminant*)

**Return type**
*EnumVariant* | None

**get_variant_by_name**(*name*)

**num_variants**()

**as_struct_ty**()

class angr.rust.sim_type.**RustSimTypeOption**

Bases: *RustSimEnum*

**copy**()

**repr**(*name=None*, *full=0*, *memo=None*, *indent=0*)

**Parameters**
**indent** (*int | None*)

**class** angr.rust.sim_type.**RustSimTypeResult**

Bases: *RustSimEnum*

**copy**()

**repr**(*name=None*, *full=0*, *memo=None*, *indent=0*)

**Parameters**
**indent** (*int | None*)

**class** angr.rust.sim_type.**RustSimTypeUnit**

Bases: *RustSimStruct*

**copy**()

**property size**

The size of the type in bits, or None if no size is computable.

**class** angr.rust.sim_type.**RustSimTypeStrRef**

Bases: *RustSimTypeSlice*

**copy**()

### 10.32.6 angr.rust.structuring

#### Submodules

*structurer_nodes*

#### angr.rust.structuring.structurer_nodes

**class** angr.rust.structuring.structurer_nodes.**PatternMatchNode**

Bases: *BaseNode*

A Rust match expression node in the structured code tree.

**__init__**(*scrutinee*, *arms*, *default_node*, *addr=None*)

**Parameters**
**arms** (*OrderedDict[tuple[EnumVariant, tuple[Statement]], SequenceNode]*)

**scrutinee**

**arms**

**default_node**

**dbg_repr**(*indent=0*)

**class** angr.rust.structuring.structurer_nodes.**IfLetNode**

Bases: *BaseNode*

A Rust if-let expression node in the structured code tree.

**__init__**(*pattern*, *scrutinee*, *true_node*, *false_node=None*, *addr=None*)

**pattern**

**scrutinee**

**true_node**

**false_node**

**dbg_repr**(*indent=0*)

## 10.32.7 angr.rust.typehoon

### Submodules

*translator*
*typehoon*

#### angr.rust.typehoon.translator

**class** angr.rust.typehoon.translator.**RustSimTypeTempRef**

Bases: *RustSimType*, *SimTypeTempRef*

Temporary reference to an unresolved type variable during translation.

**repr**(*name=None*, *full=0*, *memo=None*, *indent=0*)

**class** angr.rust.typehoon.translator.**RustTypeTranslator**

Bases: *TypeTranslator*

Bidirectional translator between Rust SimTypes and type constants.

- tc2simtype / concretize: TypeConstant -> RustSimType
- simtype2tc / lift: RustSimType -> TypeConstant

**ctype2rust**(*simtype*)

**Parameters**
**simtype** (SimType)

**arch:** Arch

**func_addr:** int | None

**known_structs:** dict[str, *SimStruct*]

**memo:** dict[str, *Struct*]

**named_struct_id_counter**

**struct_name_to_idx**

**structs**

**translated:** dict[*TypeConstant*, *SimType*]

**translated_simtypes:** dict[*SimType*, *TypeConstant*]

### angr.rust.typehoon.typehoon

**class** angr.rust.typehoon.typehoon.**RustTypehoon**

Bases: *Typehoon*

Rust-aware type inference engine extending the base Typehoon.

## 10.32.8 angr.rust.utils

### Submodules

*ail*
*demangler*
*rust_sigs*

### angr.rust.utils.ail

**class** angr.rust.utils.ail.**CallFinder**

Bases: *AILBlockViewer*

Find the first Call statement or expression in a block.

**__init__**(*include_macro=False*)

**class** angr.rust.utils.ail.**CallVisitor**

Bases: *AILBlockViewer*

Visit all Call statements and expressions in a graph, invoking a callback.

**__init__**(*callback*)

**visit**(*graph*)

angr.rust.utils.ail.**deref_vvar_and_offset**(*expr*)

If expr is a dereference of a VirtualVariable (possibly with an offset), return the VirtualVariable and offset. Otherwise, return (None, None).

**Return type**
tuple[*VirtualVariable*, int] | tuple[None, None]

angr.rust.utils.ail.**extract_vvar_and_offset**(*expr*)

If expr is a VirtualVariable (possibly with an offset), return the VirtualVariable and offset. Otherwise, return (None, None).

**Return type**
tuple[*VirtualVariable*, int] | tuple[None, None]

angr.rust.utils.ail.**find_call**(*obj*, *include_macro=False*)

**Parameters**
**obj** (*Block* | Statement | Expression)

angr.rust.utils.ail.**get_terminal_call**(*block*)

**Parameters**
**block** (*Block*)

angr.rust.utils.ail.**has_call**(*obj*, *include_macro=False*)

**Parameters**
**obj** (*Block | Statement | Expression*)

angr.rust.utils.ail.**unwrap_combo_reg_vvar_reference**(*expr*)

**Return type**
*VirtualVariable* | None

angr.rust.utils.ail.**unwrap_stack_vvar_reference**(*expr*)

**Return type**
*VirtualVariable* | None

angr.rust.utils.ail.**unwrap_stack_vvar_reference_with_offset**(*expr*)

**Return type**
tuple[*VirtualVariable*, int] | tuple[None, None]

### angr.rust.utils.demangler

angr.rust.utils.demangler.**demangle**(*s*)

angr.rust.utils.demangler.**normalize**(*name*, *monopolize=True*, *concise=False*, *use_trait_name=False*)

### angr.rust.utils.rust_sigs

angr.rust.utils.rust_sigs.**get_default_sig_dir**(*arch_name='x86_64'*, *platform='linux'*)

**Return type**
str | None

**Parameters**

- **arch_name** (*str*)
- **platform** (*str*)

## 10.33 angr.rustylib

**class** angr.rustylib.**Segment**

Bases: object

**classmethod** **__new__**(**args*, ***kwargs*)

**copy**()

**end**

**size**

**sort**

**start**

**class** angr.rustylib.**SegmentList**

Bases: object

Should be called a SegmentMap!

**classmethod __new__**(**args*, ***kwargs*)

**copy**()

**has_blocks**

**is_occupied**(*address*)

**next_free_pos**(*address*)

**next_pos_with_sort_not_in**(*address*, *sorts*, *max_distance=None*)

Returns the next occupied position that is not in the given set of sorts.

**occupied_by**(*address*)

**occupied_by_sort**(*address*)

**occupied_size**

**occupy**(*address*, *size*, *sort*)

**release**(*address*, *size*)

**search**(*addr*)

The index of the segment containing *addr* or, if *addr* is in a gap, of the next segment after it; *None* past the last segment. Segments are half-open, so the address just past a segment's end belongs to whatever follows it.

This is O(n): an index into the map cannot be computed any faster. Prefer the point-query methods (*occupied_by*, *occupied_by_sort*, ...) wherever an index is not strictly needed.

**sort_ratio_backwards**(*addr*, *window_size*, *sort*)

The fraction of bytes belonging to segments of sort *sort*, among the last *window_size* occupied bytes at or before *addr*.

The walk starts at the first segment that ends at or after *addr* (so a segment ending exactly at *addr* counts) and moves backwards, skipping over gaps, until *window_size* bytes have been covered. Returns 0.0 when the starting segment has a different sort, or when fewer than *window_size* occupied bytes are available.

**update**(*other*)

## 10.34 angr.serializable

**class** angr.serializable.**Serializable**

Bases: object

The base class of all protobuf-serializable classes in angr.

**serialize_to_cmessage**()

Serialize the class object and returns a protobuf cmessage object.

**Returns**
A protobuf cmessage object.

**Return type**
protobuf.cmessage

**serialize**()

Serialize the class object and returns a bytes object.

**Returns**
A bytes object.

**Return type**
*bytes*

**classmethod parse_from_cmessage**(*cmsg*, ***kwargs*)

Parse a protobuf cmessage and create a class object.

**Parameters**
**cmsg** – The probobuf cmessage object.

**Returns**
A unserialized class object.

**Return type**
cls

**classmethod parse**(*s*, ***kwargs*)

Parse a bytes object and create a class object.

**Parameters**
**s** (bytes) – A bytes object.

**Returns**
A class object.

**Return type**
cls

## 10.35 angr.sim_manager

**class** angr.sim_manager.**SimulationManager**

Bases: object

The Simulation Manager is the future future.

Simulation managers allow you to wrangle multiple states in a slick way. States are organized into "stashes", which you can step forward, filter, merge, and move around as you wish. This allows you to, for example, step two different stashes of states at different rates, then merge them together.

Stashes can be accessed as attributes (i.e. .active). A mulpyplexed stash can be retrieved by prepending the name with *mp_*, e.g. *.mp_active*. A single state from the stash can be retrieved by prepending the name with *one_*, e.g. *.one_active*.

Note that you shouldn't usually be constructing SimulationManagers directly - there is a convenient shortcut for creating them in `Project.factory`: see *angr.factory.AngrObjectFactory*.

The most important methods you should look at are `step`, `explore`, and `use_technique`.

**Parameters**

- **project** (angr.project.Project) – A Project instance.
- **stashes** – A dictionary to use as the stash store.
- **active_states** – Active states to seed the "active" stash with.
- **hierarchy** – A StateHierarchy object to use to track the relationships between states.

- **resilience** – A set of errors to catch during stepping to put a state in the `errore` list. You may also provide the values False, None (default), or True to catch, respectively, no errors, all angr-specific errors, and a set of many common errors.
- **save_unsat** – Set to True in order to introduce unsatisfiable states into the `unsat` stash instead of discarding them immediately.
- **auto_drop** – A set of stash names which should be treated as garbage chutes.
- **completion_mode** – A function describing how multiple exploration techniques with the `complete` hook set will interact. By default, the builtin function `any`.
- **techniques** – A list of techniques that should be pre-set to use with this manager.
- **suggestions** – Whether to automatically install the Suggestions exploration technique. Default True.

**Variables**

- **errored** – Not a stash, but a list of ErrorRecords. Whenever a step raises an exception that we catch, the state and some information about the error are placed in this list. You can adjust the list of caught exceptions with the *resilience* parameter.
- **stashes** – All the stashes on this instance, as a dictionary.
- **completion_mode** – A function describing how multiple exploration techniques with the `complete` hook set will interact. By default, the builtin function `any`.

**ALL = '_ALL'**

**DROP = '_DROP'**

**__init__**(*project*, *active_states=None*, *stashes=None*, *hierarchy=None*, *resilience=None*, *save_unsat=False*, *auto_drop=None*, *errored=None*, *completion_mode=<built-in function any>*, *techniques=None*, *suggestions=True*, ***kwargs*)

**active:** list[*SimState*]

**stashed:** list[*SimState*]

**pruned:** list[*SimState*]

**unsat:** list[*SimState*]

**deadended:** list[*SimState*]

**unconstrained:** list[*SimState*]

**found:** list[*SimState*]

**one_active:** *SimState*

**one_stashed:** *SimState*

**one_pruned:** *SimState*

**one_unsat:** *SimState*

**one_deadended:** *SimState*

**one_unconstrained:** *SimState*

**one_found:** *SimState*

**property errored:** list[*ErrorRecord*]

**property stashes:** defaultdict[str, list[*SimState*]]

**mulpyplex**(**stashes*)

Mulpyplex across several stashes.

**Parameters**
**stashes** – the stashes to mulpyplex

**Returns**
a mulpyplexed list of states from the stashes in question, in the specified order

**copy**(*deep=False*)

Make a copy of this simulation manager. Pass `deep=True` to copy all the states in it as well.

If the current callstack includes hooked methods, the already-called methods will not be included in the copy.

**use_technique**(*tech*)

Use an exploration technique with this SimulationManager.

Techniques can be found in *angr.exploration_techniques*.

**Parameters**
**tech** (ExplorationTechnique) – An ExplorationTechnique object that contains code to modify this SimulationManager's behavior.

**Returns**
The technique that was added, for convenience

**remove_technique**(*tech*)

Remove an exploration technique from a list of active techniques.

**Parameters**
**tech** (ExplorationTechnique) – An ExplorationTechnique object.

**explore**(*stash='active'*, *n=None*, *find=None*, *avoid=None*, *find_stash='found'*, *avoid_stash='avoid'*, *cfg=None*, *num_find=1*, *avoid_priority=False*, ***kwargs*)

Tick stash "stash" forward (up to "n" times or until "num_find" states are found), looking for condition "find", avoiding condition "avoid". Stores found states into "find_stash' and avoided states into "avoid_stash".

The "find" and "avoid" parameters may be any of:

- An address to find
- A set or list of addresses to find
- A function that takes a state and returns whether or not it matches.

If an angr CFG is passed in as the "cfg" parameter and "find" is either a number or a list or a set, then any states which cannot possibly reach a success state without going through a failure state will be preemptively avoided.

**run**(*stash='active'*, *n=None*, *until=None*, ***kwargs*)

Run until the SimulationManager has reached a completed state, according to the current exploration techniques. If no exploration techniques that define a completion state are being used, run until there is nothing left to run.

**Parameters**

- **stash** – Operate on this stash
- **n** – Step at most this many times
- **until** – If provided, should be a function that takes a SimulationManager and returns True or False. Stepping will terminate when it is True.

**Returns**
The simulation manager, for chaining.

**Return type**
*SimulationManager*

`complete()`

Returns whether or not this manager has reached a "completed" state.

`step(stash='active', target_stash=None, n=None, selector_func=None, step_func=None, error_list=None, successor_func=None, until=None, filter_func=None, **run_args)`

Step a stash of states forward and categorize the successors appropriately.

The parameters to this function allow you to control everything about the stepping and categorization process.

**Parameters**

- **stash** – The name of the stash to step (default: 'active')
- **target_stash** – The name of the stash to put the results in (default: same as `stash`)
- **error_list** – The list to put ErrorRecord objects in (default: `self.errored`)
- **selector_func** – If provided, should be a function that takes a state and returns a boolean. If True, the state will be stepped. Otherwise, it will be kept as-is.
- **step_func** – If provided, should be a function that takes a SimulationManager and returns a SimulationManager. Will be called with the SimulationManager at every step. Note that this function should not actually perform any stepping - it is meant to be a maintenance function called after each step.
- **successor_func** – If provided, should be a function that takes a state and return its successors. Otherwise, project.factory.successors will be used.
- **filter_func** – If provided, should be a function that takes a state and return the name of the stash, to which the state should be moved.
- **until** – (DEPRECATED) If provided, should be a function that takes a SimulationManager and returns True or False. Stepping will terminate when it is True.
- **n** – (DEPRECATED) The number of times to step (default: 1 if "until" is not provided)

Additionally, you can pass in any of the following keyword args for project.factory.successors:

**Parameters**

- **jumpkind** – The jumpkind of the previous exit
- **addr** – An address to execute at instead of the state's ip.
- **stmt_whitelist** – A list of stmt indexes to which to confine execution.
- **last_stmt** – A statement index at which to stop execution.
- **thumb** – Whether the block should be lifted in ARM's THUMB mode.

- **backup_state** – A state to read bytes from instead of using project memory.
- **opt_level** – The VEX optimization level to use.
- **insn_bytes** – A string of bytes to use for the block instead of the project.
- **size** – The maximum size of the block, in bytes.
- **num_inst** – The maximum number of instructions.
- **traceflags** – traceflags to be passed to VEX. Default: 0

**Returns**
The simulation manager, for chaining.

**Return type**
*SimulationManager*

**step_state**(*state*, *successor_func=None*, *error_list=None*, ***run_args*)

Don't use this function manually - it is meant to interface with exploration techniques.

**filter**(*state*, *filter_func=None*)

Don't use this function manually - it is meant to interface with exploration techniques.

**selector**(*state*, *selector_func=None*)

Don't use this function manually - it is meant to interface with exploration techniques.

**successors**(*state*, *successor_func=None*, ***run_args*)

Don't use this function manually - it is meant to interface with exploration techniques.

**prune**(*filter_func=None*, *from_stash='active'*, *to_stash='pruned'*)

Prune unsatisfiable states from a stash.

This function will move all unsatisfiable states in the given stash into a different stash.

**Parameters**

- **filter_func** – Only prune states that match this filter.
- **from_stash** – Prune states from this stash. (default: 'active')
- **to_stash** – Put pruned states in this stash. (default: 'pruned')

**Returns**
The simulation manager, for chaining.

**Return type**
*SimulationManager*

**populate**(*stash*, *states*)

Populate a stash with a collection of states.

**Parameters**

- **stash** – A stash to populate.
- **states** – A list of states with which to populate the stash.

**absorb**(*simgr*)

Collect all the states from `simgr` and put them in their corresponding stashes in this manager. This will not modify `simgr`.

**move**(*from_stash*, *to_stash*, *filter_func=None*)

Move states from one stash to another.

**Parameters**

- **from_stash** – Take matching states from this stash.
- **to_stash** – Put matching states into this stash.
- **filter_func** – Stash states that match this filter. Should be a function that takes a state and returns True or False. (default: stash all states)

**Returns**
The simulation manager, for chaining.

**Return type**
*SimulationManager*

**stash**(*filter_func=None*, *from_stash='active'*, *to_stash='stashed'*)

Stash some states. This is an alias for move(), with defaults for the stashes.

**Parameters**

- **filter_func** – Stash states that match this filter. Should be a function that takes a state and returns True or False. (default: stash all states)
- **from_stash** – Take matching states from this stash. (default: 'active')
- **to_stash** – Put matching states into this stash. (default: 'stashed')

**Returns**
The simulation manager, for chaining.

**Return type**
*SimulationManager*

**unstash**(*filter_func=None*, *to_stash='active'*, *from_stash='stashed'*)

Unstash some states. This is an alias for move(), with defaults for the stashes.

**Parameters**

- **filter_func** – Unstash states that match this filter. Should be a function that takes a state and returns True or False. (default: unstash all states)
- **from_stash** – take matching states from this stash. (default: 'stashed')
- **to_stash** – put matching states into this stash. (default: 'active')

**Returns**
The simulation manager, for chaining.

**Return type**
*SimulationManager*

**drop**(*filter_func=None*, *stash='active'*)

Drops states from a stash. This is an alias for move(), with defaults for the stashes.

**Parameters**

- **filter_func** – Drop states that match this filter. Should be a function that takes a state and returns True or False. (default: drop all states)
- **stash** – Drop matching states from this stash. (default: 'active')

**Returns**
The simulation manager, for chaining.

**Return type**
*SimulationManager*

**apply**(*state_func=None*, *stash_func=None*, *stash='active'*, *to_stash=None*)

Applies a given function to a given stash.

**Parameters**

- **state_func** – A function to apply to every state. Should take a state and return a state. The returned state will take the place of the old state. If the function *doesn't* return a state, the old state will be used. If the function returns a list of states, they will replace the original states.
- **stash_func** – A function to apply to the whole stash. Should take a list of states and return a list of states. The resulting list will replace the stash. If both state_func and stash_func are provided state_func is applied first, then stash_func is applied on the results.
- **stash** – A stash to work with.
- **to_stash** – If specified, this stash will be used to store the resulting states instead.

**Returns**
The simulation manager, for chaining.

**Return type**
*SimulationManager*

**split**(*stash_splitter=None*, *stash_ranker=None*, *state_ranker=None*, *limit=8*, *from_stash='active'*, *to_stash='stashed'*)

Split a stash of states into two stashes depending on the specified options.

The stash from_stash will be split into two stashes depending on the other options passed in. If to_stash is provided, the second stash will be written there.

stash_splitter overrides stash_ranker, which in turn overrides state_ranker. If no functions are provided, the states are simply split according to the limit.

The sort done with state_ranker is ascending.

**Parameters**

- **stash_splitter** – A function that should take a list of states and return a tuple of two lists (the two resulting stashes).
- **stash_ranker** – A function that should take a list of states and return a sorted list of states. This list will then be split according to "limit".
- **state_ranker** – An alternative to stash_splitter. States will be sorted with outputs of this function, which are to be used as a key. The first "limit" of them will be kept, the rest split off.
- **limit** – For use with state_ranker. The number of states to keep. Default: 8
- **from_stash** – The stash to split (default: 'active')
- **to_stash** – The stash to write to (default: 'stashed')

**Returns**
The simulation manager, for chaining.

**Return type**
*SimulationManager*

**merge**(*merge_func=None*, *merge_key=None*, *stash='active'*, *prune=True*)

Merge the states in a given stash.

**Parameters**

- **stash** – The stash (default: 'active')
- **merge_func** – If provided, instead of using state.merge, call this function with the states as the argument. Should return the merged state.
- **merge_key** – If provided, should be a function that takes a state and returns a key that will compare equal for all states that are allowed to be merged together, as a first approximation. By default: uses PC, callstack, and open file descriptors.
- **prune** – Whether to prune the stash prior to merging it

**Returns**
The simulation manager, for chaining.

**Return type**
*SimulationManager*

**class** angr.sim_manager.**ErrorRecord**

Bases: object

A container class for a state and an error that was thrown during its execution. You can find these in SimulationManager.errored.

**Variables**

- **state** (*SimState*) – The state that encountered an error, at the point in time just before the erroring step began.
- **error** (Exception) – The error that was thrown.
- **traceback** (TracebackType) – The traceback for the error that was thrown.

**__init__**(*state*, *error*, *traceback*)

**state:** *SimState*

**error:** Exception

**traceback:** TracebackType

**debug**()

Launch a postmortem debug shell at the site of the error.

**reraise**()

## 10.36 angr.sim_options

## 10.37 angr.sim_procedure

**class** angr.sim_procedure.**SimProcedure**

Bases: object

A SimProcedure is a wonderful object which describes a procedure to run on a state.

You may subclass SimProcedure and override `run()`, replacing it with mutating `self.state` however you like, and then either returning a value or jumping away somehow.

A detailed discussion of programming SimProcedures may be found at https://docs.angr.io/extending-angr/simprocedures

**Parameters**

- **arch** – The architecture to use for this procedure
- **symbolic_return** – Whether the procedure's return value should be stubbed into a single symbolic variable constratined to the real return value
- **returns** – Whether the procedure should return to its caller afterwards
- **is_syscall** – Whether this procedure is a syscall
- **num_args** – The number of arguments this procedure should extract
- **display_name** – The name to use when displaying this procedure
- **library_name** – The name of the library from which the function we're emulating comes
- **cc** (*SimCC* | None) – The SimCC to use for this procedure
- **sim_kwargs** – Additional keyword arguments to be passed to run()
- **is_function** – Whether this procedure emulates a function

The following class variables should be set if necessary when implementing a new SimProcedure:

**Variables**

- **NO_RET** – Set this to true if control flow will never return from this function
- **DYNAMIC_RET** – Set this to true if whether the control flow returns from this function or not depends on the context (e.g., libc's error() call). Must implement dynamic_returns() method.
- **ADDS_EXITS** – Set this to true if you do any control flow other than returning
- **IS_FUNCTION** – Does this procedure simulate a function? True by default
- **ARGS_MISMATCH** – Does this procedure have a different list of arguments than what is provided in the function specification? This may happen when we manually extract arguments in the run() method of a SimProcedure. False by default.
- **local_vars** (tuple[str, ...]) – If you use `self.call()`, set this to a list of all the local variable names in your class. They will be restored on return.

The following instance variables are available when working with simprocedures from the inside or the outside:

**Variables**

- **project** – The associated angr project
- **arch** – The associated architecture
- **addr** – The linear address at which the procedure is executing
- **cc** – The calling convention in use for engaging with the ABI
- **canonical** – The canonical version of this SimProcedure. Procedures are deepcopied for many reasons, including to be able to store state related to a specific run and to be able to hook continuations.
- **kwargs** – Any extra keyword arguments used to construct the procedure; will be passed to run
- **display_name** – See the eponymous parameter
- **library_name** – See the eponymous parameter

- **abi** – If this is a syscall simprocedure, which ABI are we using to map the syscall numbers?
- **symbolic_return** – See the eponymous parameter
- **syscall_number** – If this procedure is a syscall, the number will be populated here.
- **returns** – See eponymous parameter and NO_RET cvar
- **is_syscall** – See eponymous parameter
- **is_function** – See eponymous parameter and cvar
- **is_stub** – See eponymous parameter
- **is_continuation** – Whether this procedure is the original or a continuation resulting from `self.call()`
- **continuations** – A mapping from name to each known continuation
- **run_func** – The name of the function implementing the procedure. "run" by default, but different in continuations.
- **num_args** – The number of arguments to the procedure. If not provided in the parameter, extracted from the definition of `self.run`

The following instance variables are only used in a copy of the procedure that is actually executing on a state:

**Variables**

- **state** (*SimState*) – The SimState we should be mutating to perform the procedure
- **successors** – The SimSuccessors associated with the current step
- **arguments** – The function arguments, deserialized from the state
- **arg_session** (*ArgSession* | `int` | `None`) – The ArgSession that was used to parse arguments out of the state, in case you need it for varargs
- **use_state_arguments** – Whether we're using arguments extracted from the state or manually provided
- **ret_to** – The current return address
- **ret_expr** – The computed return value
- **call_ret_expr** – The return value from having used `self.call()`
- **inhibit_autoret** – Whether we should avoid automatically adding an exit for returning once the run function ends
- **arg_session** – The ArgSession object that was used to extract the runtime argument values. Useful for if you want to extract variadic args.

**__init__**(*project=None*, *cc=None*, *prototype=None*, *symbolic_return=None*, *returns=None*, *is_syscall=False*, *is_stub=False*, *num_args=None*, *display_name=None*, *library_name=None*, *is_function=None*, ***kwargs*)

**Parameters**

- **project** (Project | *None*)
- **cc** (SimCC | *None*)
- **prototype** (*str* | SimTypeFunction | *None*)

**state:** *SimState*

**arg_session:** *ArgSession* | int | None

**execute**(*state*, *successors=None*, *arguments=None*, *ret_to=None*)

Call this method with a SimState and a SimSuccessors to execute the procedure.

Alternately, successors may be none if this is an inline call. In that case, you should provide arguments to the function.

**make_continuation**(*name*)

**NO_RET = False**

**DYNAMIC_RET = False**

**ADDS_EXITS = False**

**IS_FUNCTION = True**

**ARGS_MISMATCH = False**

**ALT_NAMES = None**

**local_vars:** tuple[str, ...] = ()

**run**(**args*, ***kwargs*)

Implement the actual procedure here!

**Return type**
Any

**static_exits**(*blocks*, ***kwargs*)

Get new exits by performing static analysis and heuristics. This is a fast and best-effort approach to get new exits for scenarios where states are not available (e.g. when building a fast CFG).

**Parameters**
**blocks** (*list*) – Blocks that are executed before reaching this SimProcedure.

**Returns**
A list of dicts. Each dict should contain the following entries: 'address', 'jumpkind', and 'namehint'.

**Return type**
list

**dynamic_returns**(*blocks*, ***kwargs*)

Determines if a call to this function returns or not by performing static analysis and heuristics.

**Parameters**
**blocks** – Blocks that are executed before reaching this SimProcedure.

**Return type**
bool

**Returns**
True if the call returns, False otherwise.

**property should_add_successors**

**set_args**(*args*)

**va_arg**(*ty*, *index=None*)

**inline_call**(*procedure*, **arguments*, ***kwargs*)

Call another SimProcedure in-line to retrieve its return value. Returns an instance of the procedure with the ret_expr property set.

**Parameters**

- **procedure** – The class of the procedure to execute
- **arguments** – Any additional positional args will be used as arguments to the procedure call
- **sim_kwargs** – Any additional keyword args will be passed as sim_kwargs to the procedure constructor

**fix_prototype_returnty**(*ret_size*)

**ret**(*expr=None*)

Add an exit representing a return from this function. If this is not an inline call, grab a return address from the state and jump to it. If this is not an inline call, set a return expression with the calling convention.

**call**(*addr*, *args*, *continue_at*, *cc=None*, *prototype=None*, *jumpkind='Ijk_Call'*)

Add an exit representing calling another function via pointer.

**Parameters**

- **addr** – The address of the function to call
- **args** – The list of arguments to call the function with
- **continue_at** – Later, when the called function returns, execution of the current procedure will continue in the named method.
- **cc** – Optional: use this calling convention for calling the new function. Default is to use the current convention.
- **prototype** – Optional: The prototype to use for the call. Will default to all-ints.

**jump**(*addr*, *jumpkind='Ijk_Boring'*)

Add an exit representing jumping to an address.

**exit**(*exit_code*)

Add an exit representing terminating the program.

**property is_java**

**property argument_types**

**property return_type**

## 10.38 angr.sim_state

angr.sim_state.**arch_overridable**(*f*)

**class** angr.sim_state.**SimState**

Bases: *PluginHub*[*SimStatePlugin*], Generic[IPTypeConc, IPTypeSym]

The SimState represents the state of a program, including its memory, registers, and so forth.

**Parameters**

**project** (*Project*) – The project instance.

**Variables**

- **regs** (*SimRegNameView*) – A convenient view of the state's registers, where each register is a property
- **mem** – A convenient view of the state's memory, a *angr.state_plugins.view.SimMemView*
- **registers** (*DefaultMemory*) – The state's register file as a flat memory region
- **memory** (*DefaultMemory*) – The state's memory as a flat memory region
- **solver** (*SimSolver*) – The symbolic solver and variable manager for this state
- **inspect** – The breakpoint manager, a *angr.state_plugins.inspect.SimInspector*
- **log** – Information about the state's history
- **scratch** (*SimStateScratch*) – Information about the current execution step
- **posix** – MISNOMER: information about the operating system or environment model
- **fs** (*SimFilesystem*) – The current state of the simulated filesystem
- **libc** (*SimStateLibc*) – Information about the standard library we are emulating
- **cgc** – Information about the cgc environment
- **uc_manager** – Control of under-constrained symbolic execution
- **unicorn** – Control of the Unicorn Engine

**solver:** *SimSolver*

**posix:** *SimSystemPosix*

**fs:** *SimFilesystem*

**libc:** *SimStateLibc*

**registers:** *DefaultMemory*

**regs:** *SimRegNameView*

**memory:** *DefaultMemory*

**callstack:** *CallStack*

**mem:** *SimMemView*

**history:** *SimStateHistory*

**inspect:** *SimInspector*

**jni_references:** *SimStateJNIReferences*

**scratch:** *SimStateScratch*

**heap:** *SimHeapBase*

**__init__**(*project*, *plugins=None*, *mode=None*, *options=None*, *add_options=None*, *remove_options=None*, *special_memory_filler=None*, *os_name=None*, *plugin_preset='default'*, *cle_memory_backer=None*, *dict_memory_backer=None*, *permissions_map=None*, *default_permissions=3*, *stack_perms=None*, *stack_end=None*, *stack_size=None*, *regioned_memory_cls=None*, ***kwargs*)

**Parameters**

- **project** (Project)
- **plugins** (*dict[str, SimStatePlugin] | None*)
- **mode** (*str | None*)
- **options** (*set[str] | list[str] | SimStateOptions | None*)
- **add_options** (*set[str] | None*)
- **remove_options** (*set[str] | None*)
- **special_memory_filler** (*Callable[[str, int, int, SimState], Any] | None*)
- **os_name** (*str | None*)
- **plugin_preset** (*str*)
- **cle_memory_backer** (*Clemory | None*)
- **dict_memory_backer** (*dict[int, bytes] | None*)
- **permissions_map** (*dict[tuple[int, int], int] | None*)
- **default_permissions** (*int*)
- **stack_perms** (*int | None*)
- **stack_end** (*int | None*)
- **stack_size** (*int | None*)

**property plugins**

**property ip**

Get the instruction pointer expression, trigger SimInspect breakpoints, and generate SimActions. Use `_ip` to not trigger breakpoints or generate actions.

**Returns**
an expression

**property addr: IPTypeConc**

Get the concrete address of the instruction pointer, without triggering SimInspect breakpoints or generating SimActions. An integer is returned, or an exception is raised if the instruction pointer is symbolic.

**Returns**
an int

**Setter accepts**
int | SootAddressDescriptor | tuple[int, int]

**property arch: Arch**

The architecture of the state. This is the project's architecture, except for JavaVM projects with JNI support, where it is either the Soot or the native architecture, depending on whether the current ip is a Soot address.

**property javavm_memory**

In case of an JavaVM with JNI support, a state can store the memory plugin twice; one for the native and one for the java view of the state.

**Returns**
The JavaVM view of the memory plugin.

**property javavm_registers**

In case of an JavaVM with JNI support, a state can store the registers plugin twice; one for the native and one for the java view of the state.

**Returns**
The JavaVM view of the registers plugin.

**simplify**(**args*)

Simplify this state's constraints.

**add_constraints**(**constraints*)

Add some constraints to the state.

You may pass in any number of symbolic booleans as variadic positional arguments.

**satisfiable**(***kwargs*)

Whether the state's constraints are satisfiable

**downsize**()

Clean up after the solver engine. Calling this when a state no longer needs to be solved on will reduce memory usage.

**step**(***kwargs*)

Perform a step of symbolic execution using this state. Any arguments to *AngrObjectFactory.successors* can be passed to this.

**Returns**
A SimSuccessors object categorizing the results of the step.

**block**(**args*, ***kwargs*)

Represent the basic block at this state's instruction pointer. Any arguments to *AngrObjectFactory.block* can ba passed to this.

**Returns**
A Block object describing the basic block of code at this point.

**copy**()

Returns a copy of the state.

**merge**(**others*, ***kwargs*)

Merges this state with the other states. Returns the merging result, merged state, and the merge flag.

**Parameters**

- **states** – the states to merge
- **merge_conditions** – a tuple of the conditions under which each state holds
- **common_ancestor** – a state that represents the common history between the states being merged. Usually it is only available when EFFICIENT_STATE_MERGING is enabled, otherwise weak-refed states might be dropped from state history instances.
- **plugin_whitelist** – a list of plugin names that will be merged. If this option is given and is not None, any plugin that is not inside this list will not be merged, and will be created as a fresh instance in the new state.
- **common_ancestor_history** – a SimStateHistory instance that represents the common history between the states being merged. This is to allow optimal state merging when EFFICIENT_STATE_MERGING is disabled.

**Returns**
(merged state, merge flag, a bool indicating if any merging occurred)

**reg_concrete**(**args*, ***kwargs*)

Returns the contents of a register but, if that register is symbolic, raises a SimValueError.

**mem_concrete**(**args*, ***kwargs*)

Returns the contents of a memory but, if the contents are symbolic, raises a SimValueError.

**stack_push**(*thing*)

Push 'thing' to the stack, writing the thing to memory and adjusting the stack pointer.

**stack_pop**()

Pops from the stack and returns the popped thing. The length will be the architecture word size.

**stack_read**(*offset*, *length*, *bp=False*)

Reads length bytes, at an offset into the stack.

**Parameters**

- **offset** – The offset from the stack pointer.
- **length** – The number of bytes to read.
- **bp** – If True, offset from the BP instead of the SP. Default: False.

**make_concrete_int**(*expr*)

**dbg_print_stack**(*depth=None*, *sp=None*)

Only used for debugging purposes. Return the current stack info in formatted string. If depth is None, the current stack frame (from sp to bp) will be printed out.

**set_mode**(*mode*)

**property thumb**

## 10.39 angr.sim_state_options

**class** angr.sim_state_options.**StateOption**

Bases: object

Describes a state option.

**__init__**(*name*, *types*, *default='_NO_DEFAULT_VALUE'*, *description=None*)

**name**

**types**

**default**

**description**

**property has_default_value**

**one_type**()

**class** angr.sim_state_options.**SimStateOptions**

Bases: object

A per-state manager of state options. An option can be either a key-valued entry or a Boolean switch (which can be seen as a key-valued entry whose value can only be either True or False).

```
OPTIONS = {'ABSTRACT_MEMORY': <0 ABSTRACT_MEMORY[bool]>, 'ABSTRACT_SOLVER': <0

```

**__init__**(*thing*)

**Parameters**
**thing** – Either a set of Boolean switches to enable, or an existing SimStateOptions instance.

**add**(*boolean_switch*)

[COMPATIBILITY] Enable a Boolean switch.

**Parameters**
**boolean_switch** (*str*) – Name of the Boolean switch.

**Returns**
None

**update**(*boolean_switches*)

[COMPATIBILITY] In order to be compatible with the old interface, you can enable a collection of Boolean switches at the same time by doing the following:

```
>>> state.options.update({sim_options.SYMBOLIC, sim_options.ABSTRACT_MEMORY})
```

or

```
>>> state.options.update(sim_options.unicorn)
```

**Parameters**
**boolean_switches** (*set*) – A collection of Boolean switches to enable.

**Returns**
None

**remove**(*name*)

Drop a state option if it exists, or raise a KeyError if the state option is not set.

[COMPATIBILITY] Remove a Boolean switch.

**Parameters**
**name** (*str*) – Name of the state option.

**Returns**
NNone

**discard**(*name*)

Drop a state option if it exists, or silently return if the state option is not set.

[COMPATIBILITY] Disable a Boolean switch.

**Parameters**
**name** (*str*) – Name of the Boolean switch.

**Returns**
None

**difference**(*boolean_switches*)

[COMPATIBILITY] Make a copy of the current instance, and then discard all options that are in boolean_switches.

**Parameters**
**boolean_switches** (*set*) – A collection of Boolean switches to disable.

**Returns**
A new SimStateOptions instance.

`copy()`

Get a copy of the current SimStateOptions instance.

**Returns**
A new SimStateOptions instance.

**Return type**
*SimStateOptions*

`tally(exclude_false=True, description=False)`

Return a string representation of all state options.

**Parameters**

- **exclude_false** (*bool*) – Whether to exclude Boolean switches that are disabled.
- **description** (*bool*) – Whether to display the description of each option.

**Returns**
A string representation.

**Return type**
str

`classmethod register_option(name, types, default=None, description=None)`

Register a state option.

**Parameters**

- **name** (*str*) – Name of the state option.
- **types** – A collection of allowed types of this state option.
- **default** – The default value of this state option.
- **description** (*str*) – The description of this state option.

**Returns**
None

`classmethod register_bool_option(name, description=None)`

Register a Boolean switch as state option. This is equivalent to cls.register_option(name, set([bool]), description=description)

**Parameters**

- **name** (*str*) – Name of the state option.
- **description** (*str*) – The description of this state option.

**Returns**
None

## 10.40 angr.sim_type

`class angr.sim_type.SimType`

Bases: `object`

SimType exists to track type information for SimProcedures.

**base:** *bool* = True

**__init__**(*label=None*, *qualifier=None*)

**Parameters**

- **label** – the type label.
- **qualifier** (*Iterable[str] | None*)

**property size:** *int | None*

The size of the type in bits, or None if no size is computable.

**property alignment**

The alignment of the type in bytes.

**with_arch**(*arch*, *memo=None*)

**Return type**
Self

**Parameters**

- **arch** (*Arch | None*)
- **memo** (*dict[str, SimType] | None*)

**c_repr**(*name=None*, *full=0*, *memo=None*, *indent=0*, *name_parens=True*)

**Parameters**

- **indent** (*int | None*)
- **name_parens** (*bool*)

**copy**()

**extract**(*state*, *addr*, *concrete=False*)

**Return type**
Any

**Parameters**

- **state** (SimState)
- **concrete** (*bool*)

**store**(*state*, *addr*, *value*)

**Parameters**

- **state** (SimState)
- **value** (*Any*)

**extract_claripy**(*bits*)

Given a bitvector *bits* which was loaded from memory in a big-endian fashion, return a more appropriate or structured representation of the data.

A type must have an arch associated in order to use this method.

**Return type**
Any

to_json(*fields=None*, *memo=None*)

Serialize the type class to a JSON-compatible dictionary.

**Return type**
dict[str, Any]

**Parameters**

- **fields** (*Iterable[str] | None*)
- **memo** (*dict[str, SimTypeRef] | None*)

static from_json(*d*, *type_collection=None*, *memo=None*, *decoded=None*)

Deserialize a type class from a JSON-compatible dictionary.

**Parameters**

- **type_collection** (*SimTypeCollection* | None) – Resolve type references against this collection.
- **memo** (set[str] | None) – Names of types that are being loaded from the type collection (recursion guard).
- **decoded** (dict[str, *SimType*] | None) – Named structs decoded so far in this document. to_json() emits a reference for every repeated occurrence of a named struct, which is resolved here.
- **d** (*dict[str, Any]*)

class angr.sim_type.**TypeRef**

Bases: *SimType*

A TypeRef is a reference to a type with a name. This allows for interactivity in type analysis, by storing a type and having the option to update it later and have all references to it automatically update as well.

property ty

property type

property name

This is a read-only property because it is desirable to store typerefs in a mapping from name to type, and we want the mapping to be in the loop for any updates.

property size

The size of the type in bits, or None if no size is computable.

property alignment

The alignment of the type in bytes.

with_arch(*arch*, *memo=None*)

**Parameters**
**memo** (*dict[str, SimType] | None*)

c_repr(*name=None*, *full=0*, *memo=None*, *indent=0*, *name_parens=True*)

**Parameters**
**name_parens** (*bool*)

copy()

class angr.sim_type.**NamedTypeMixin**

Bases: object

SimType classes with this mixin in the class hierarchy allows setting custom class names. A typical use case is to represent same or similar type classes with different qualified names, such as "std::basic_string" vs "std::__cxx11::basic_string". In such cases, .name stores the qualified name, and .unqualified_name() returns the unqualified name of the type.

**__init__**(**args*, *name=None*, ***kwargs*)

**Parameters**
**name** (*str | None*)

property **name: str**

**unqualified_name**(*lang='c++'*)

**Return type**
str

**Parameters**
**lang** (*str*)

class angr.sim_type.**SimTypeBottom**

Bases: *SimType*

SimTypeBottom basically represents a type error.

**c_repr**(*name=None*, *full=0*, *memo=None*, *indent=0*, *name_parens=True*)

**Parameters**
**name_parens** (*bool*)

**copy**()

class angr.sim_type.**SimTypeTop**

Bases: *SimType*

SimTypeTop represents any type (mostly used with a pointer for void*).

**copy**()

class angr.sim_type.**SimTypeReg**

Bases: *SimType*

SimTypeReg is the base type for all types that are register-sized.

**__init__**(*size*, *label=None*, *qualifier=None*)

**Parameters**

- **label** – the type label.
- **size** (int | None) – the size of the type (e.g. 32bit, 8bit, etc.).
- **qualifier** (*Iterable | None*)

**store**(*state*, *addr*, *value*)

**Parameters**
**value** (*int | BV*)

**copy**()

class angr.sim_type.**SimTypeNum**

Bases: *SimType*

SimTypeNum is a numeric type of arbitrary length

**__init__**(*size*, *signed=True*, *label=None*, *qualifier=None*)

**Parameters**

- **size** (int) – The size of the integer, in bits
- **signed** – Whether the integer is signed or not
- **label** – A label for the type
- **qualifier** (*Iterable | None*)

**property size: int**

The size of the type in bits, or None if no size is computable.

**extract**(*state*, *addr*, *concrete=False*)

**Overloads**

- **state**, **addr**, **concrete** (Literal[False]) = ... → BV
- **state**, **addr**, **concrete** (Literal[True]) → int

**store**(*state*, *addr*, *value*)

**Parameters**
**value** (*int | BV*)

**copy**()

class angr.sim_type.**SimTypeInt**

Bases: *SimTypeReg*

SimTypeInt is a type that specifies a signed or unsigned C integer.

**__init__**(*signed=True*, *label=None*, *qualifier=None*)

**Parameters**

- **signed** – True if signed, False if unsigned
- **label** – The type label
- **qualifier** (*Iterable | None*)

**c_repr**(*name=None*, *full=0*, *memo=None*, *indent=0*, *name_parens=True*)

**Parameters**
**name_parens** (*bool*)

**property size**

The size of the type in bits, or None if no size is computable.

**extract**(*state*, *addr*, *concrete=False*)

**Overloads**

- **state**, **addr**, **concrete** (Literal[False]) = ... → BV
- **state**, **addr**, **concrete** (Literal[True]) → int

**copy**()

**class** angr.sim_type.**SimTypeShort**

Bases: *SimTypeInt*

**class** angr.sim_type.**SimTypeLong**

Bases: *SimTypeInt*

**class** angr.sim_type.**SimTypeLongLong**

Bases: *SimTypeInt*

**class** angr.sim_type.**SimTypeFixedSizeInt**

Bases: *SimTypeInt*

The base class for all fixed-size (i.e., the size stays the same on all platforms) integer types. Do not instantiate this class directly.

**c_repr**(*name=None*, *full=0*, *memo=None*, *indent=0*, *name_parens=True*)

**Parameters**

- **indent** (*int | None*)
- **name_parens** (*bool*)

**property size:** int

The size of the type in bits, or None if no size is computable.

**class** angr.sim_type.**SimTypeInt128**

Bases: *SimTypeFixedSizeInt*

**class** angr.sim_type.**SimTypeInt256**

Bases: *SimTypeFixedSizeInt*

**class** angr.sim_type.**SimTypeInt512**

Bases: *SimTypeFixedSizeInt*

**class** angr.sim_type.**SimTypeChar**

Bases: *SimTypeReg*

SimTypeChar is a type that specifies a character; this could be represented by a byte, but this is meant to be interpreted as a character.

**__init__**(*signed=True*, *label=None*, *qualifier=None*)

**Parameters**

- **label** – the type label.
- **qualifier** (*Iterable | None*)

**store**(*state*, *addr*, *value*)

**Parameters**
**value** (*int | BV*)

**extract**(*state*, *addr*, *concrete=False*)

**Overloads**

- **state**, **addr**, **concrete** (Literal[False]) = ... → BV
- **state**, **addr**, **concrete** (Literal[True]) → bytes

**Parameters**
**concrete** (*bool*)

**Return type**
*BV* | *bytes*

**copy**()

class angr.sim_type.**SimTypeWideChar**

Bases: *SimTypeReg*

SimTypeWideChar is a type that specifies a wide character (a UTF-16 character).

**__init__**(*signed=True*, *label=None*, *endness=Endness.BE*, *qualifier=None*)

**Parameters**

- **label** – the type label.
- **endness** (*Endness*)
- **qualifier** (*Iterable | None*)

**store**(*state*, *addr*, *value*)

**Parameters**
**value** (*int | BV*)

**extract**(*state*, *addr*, *concrete=False*)

**Return type**
Any

**copy**()

class angr.sim_type.**SimTypeBool**

Bases: *SimTypeReg*

**__init__**(*signed=True*, *label=None*, *qualifier=None*)

**Parameters**

- **label** – the type label.
- **qualifier** (*Iterable | None*)

**store**(*state*, *addr*, *value*)

**Parameters**
**value** (*int | BV | bool*)

**extract**(*state*, *addr*, *concrete=False*)

**Overloads**

- **state**, **addr**, **concrete** (Literal[False]) = ... → Bool
- **state**, **addr**, **concrete** (Literal[True]) → bool

**copy**()

class angr.sim_type.**SimTypeFd**

Bases: *SimTypeReg*

SimTypeFd is a type that specifies a file descriptor.

__init__(*label=None*, *qualifier=None*)

**Parameters**

- **label** – the type label
- **qualifier** (*Iterable | None*)

property size

The size of the type in bits, or None if no size is computable.

copy()

extract(*state*, *addr*, *concrete=False*)

**Overloads**

- **state**, **addr**, **concrete** (Literal[False]) = ... → BV
- **state**, **addr**, **concrete** (Literal[True]) → int

class angr.sim_type.**PointerDisposition**

Bases: IntEnum

IN_OUT = 0

IN = 1

OUT = 2

IN_OUTMAYBE = 3

OUTMAYBE = 4

NONE = 5

UNKNOWN = 6

__new__(*value*)

class angr.sim_type.**SimTypePointer**

Bases: *SimTypeReg*

SimTypePointer is a type that specifies a pointer to some other type.

__init__(*pts_to*, *label=None*, *offset=0*, *qualifier=None*, *disposition=PointerDisposition.UNKNOWN*)

**Parameters**

- **label** – The type label.
- **pts_to** (*SimType*) – The type to which this pointer points.
- **qualifier** (*Iterable[str] | None*)
- **disposition** (PointerDisposition | *int*)

c_repr(*name=None*, *full=0*, *memo=None*, *indent=0*, *name_parens=True*)

**Parameters**
**name_parens** (*bool*)

make(*pts_to*)

**property size**

The size of the type in bits, or None if no size is computable.

**copy**()

**extract**(*state*, *addr*, *concrete=False*)

**Overloads**

- **state**, **addr**, **concrete** (Literal[False]) = ... → BV
- **state**, **addr**, **concrete** (Literal[True]) → int

class angr.sim_type.**SimTypeReference**

Bases: *SimTypeReg*

SimTypeReference is a type that specifies a reference to some other type.

**refs:** *SimType*

**c_repr**(*name=None*, *full=0*, *memo=None*, *indent=0*, *name_parens=True*)

**Parameters**

**name_parens** (*bool*)

**make**(*refs*)

**property size**

The size of the type in bits, or None if no size is computable.

**copy**()

**extract**(*state*, *addr*, *concrete=False*)

**Overloads**

- **state**, **addr**, **concrete** (Literal[False]) = ... → BV
- **state**, **addr**, **concrete** (Literal[True]) → int

class angr.sim_type.**SimTypeArray**

Bases: *SimType*

SimTypeArray is a type that specifies a series of data laid out in sequence.

**__init__**(*elem_type*, *length=None*, *label=None*, *qualifier=None*)

**Parameters**

- **label** – The type label.
- **elem_type** – The type of each element in the array.
- **length** – An expression of the length of the array, if known.
- **qualifier** (*Iterable | None*)

**elem_type:** *SimType*

**length:** int | None

**c_repr**(*name=None*, *full=0*, *memo=None*, *indent=0*, *name_parens=True*)

**Parameters**

**name_parens** (*bool*)

**property size**

The size of the type in bits, or None if no size is computable.

**property alignment**

The alignment of the type in bytes.

**copy**()

**extract**(*state*, *addr*, *concrete=False*)

**Overloads**

- **state**, **addr**, **concrete** (Literal[False]) = ... → list[Any]
- **state**, **addr**, **concrete** (Literal[True]) = ... → list[Any]

**store**(*state*, *addr*, *value*)

**Parameters**
**value** (*list[int | BV]*)

angr.sim_type.**SimTypeFixedSizeArray**

alias of *SimTypeArray*

**class** angr.sim_type.**SimTypeString**

Bases: *NamedTypeMixin*, *SimType*

SimTypeString is a type that represents a C-style string, i.e. a NUL-terminated array of bytes.

**__init__**(*length=None*, *label=None*, *name=None*, *qualifier=None*)

**Parameters**

- **label** – The type label.
- **length** (int | None) – An expression of the length of the string, if known.
- **name** (*str | None*)
- **qualifier** (*Iterable | None*)

**c_repr**(*name=None*, *full=0*, *memo=None*, *indent=0*, *name_parens=True*)

**Parameters**
**name_parens** (*bool*)

**extract**(*state*, *addr*, *concrete=False*)

**Overloads**

- **state**, **addr**, **concrete** (Literal[False]) = ... → BV
- **state**, **addr**, **concrete** (Literal[True]) → bytes

**Parameters**
**state** (SimState)

**property size**

The size of the type in bits, or None if no size is computable.

**property alignment**

The alignment of the type in bytes.

**copy**()

class angr.sim_type.**SimTypeWString**

Bases: *NamedTypeMixin*, *SimType*

A wide-character null-terminated string, where each character is 2 bytes.

**c_repr**(*name=None*, *full=0*, *memo=None*, *indent=0*, *name_parens=True*)

**Parameters**
**name_parens** (*bool*)

**extract**(*state*, *addr*, *concrete=False*)

**store**(*state*, *addr*, *value*)

**property size**

The size of the type in bits, or None if no size is computable.

**property alignment**

The alignment of the type in bytes.

**copy**()

class angr.sim_type.**SimTypeFunction**

Bases: *SimType*

SimTypeFunction is a type that specifies an actual function (i.e. not a pointer) with certain types of arguments and a certain return value.

**base: bool = False**

**__init__**(*args*, *returnty*, *label=None*, *arg_names=None*, *variadic=False*)

**Parameters**

- **label** – The type label
- **args** (Iterable[*SimType*]) – A tuple of types representing the arguments to the function
- **returnty** (*SimType* | None) – The return type of the function, or none for void
- **variadic** – Whether the function accepts varargs
- **arg_names** (*Iterable[str] | None*)

**args: tuple[SimType, ...]**

**returnty: SimType | None**

**arg_names: tuple[str, ...]**

**c_repr**(*name=None*, *full=0*, *memo=None*, *indent=0*, *name_parens=True*, *show_void=True*)

**Parameters**

- **name_parens** (*bool*)
- **show_void** (*bool*)

**property size**

The size of the type in bits, or None if no size is computable.

**copy**()

class angr.sim_type.**SimTypeCppFunction**

Bases: *SimTypeFunction*

SimTypeCppFunction is a type that specifies an actual C++-style function with information about arguments, return value, and more C++-specific properties.

**Variables**

- **ctor** – Whether the function is a constructor or not.
- **dtor** – Whether the function is a destructor or not.

**copy**()

class angr.sim_type.**SimTypeLength**

Bases: *SimTypeLong*

SimTypeLength is a type that specifies the length of some buffer in memory.

...I'm not really sure what the original design of this class was going for

**__init__**(*signed=False*, *addr=None*, *length=None*, *label=None*)

**Parameters**

- **signed** – Whether the value is signed or not
- **label** – The type label.
- **addr** – The memory address (expression).
- **length** – The length (expression).

**property size**

The size of the type in bits, or None if no size is computable.

**copy**()

class angr.sim_type.**SimTypeFloat**

Bases: *SimTypeReg*

An IEEE754 single-precision floating point number

**sort = FSORT_32**

**signed = True**

**property size: int**

The size of the type in bits, or None if no size is computable.

**extract**(*state*, *addr*, *concrete=False*)

**store**(*state*, *addr*, *value*)

**Parameters**

**value** (*int | BV | FP*)

**copy**()

class angr.sim_type.**SimTypeDouble**

Bases: *SimTypeFloat*

An IEEE754 double-precision floating point number

sort = FSORT_64

property size: int

The size of the type in bits, or None if no size is computable.

property alignment

The alignment of the type in bytes.

copy()

class angr.sim_type.SimTypeLongDouble

Bases: *SimTypeFloat*

An x87 80-bit extended-precision floating point number (long double on i386/amd64). Stored as 10 bytes with platform-dependent padding (12 bytes on i386, 16 on amd64).

sort = FSORT_64

property size: int

The size of the type in bits, or None if no size is computable.

property alignment

The alignment of the type in bytes.

copy()

class angr.sim_type.SimTypeM128

Bases: *SimTypeReg*

A 128-bit SSE vector, printed by its Intel-intrinsics name: `__m128i` (integer lanes), `__m128` (float lanes) or `__m128d` (double lanes).

LANE_NAMES = {'double': '__m128d', 'float': '__m128', 'int': '__m128i'}

property size: int

The size of the type in bits, or None if no size is computable.

property alignment

The alignment of the type in bytes.

c_repr(*name=None*, *full=0*, *memo=None*, *indent=0*, *name_parens=True*)

**Parameters**

- **indent** (*int | None*)
- **name_parens** (*bool*)

copy()

class angr.sim_type.SimTypeFloat128

Bases: *SimTypeFloat*

An IEEE754 quadruple-precision (binary128) floating point number. It is *long double* on architectures whose ABI defines it so (s390x, aarch64, riscv64, mips64) and *__float128* elsewhere.

sort = FSORT_64

property size: int

The size of the type in bits, or None if no size is computable.

property alignment

The alignment of the type in bytes.

copy()

class angr.sim_type.SimStruct

Bases: *NamedTypeMixin*, *SimType*

fields: OrderedDict[str, *SimType*]

property pack

property def_order

property align

property packed

property offsets: dict[str, int]

extract(*state*, *addr*, *concrete=False*)

**Return type**
*SimStructValue*

fixup_bitfield_offsets(*arch*)

Fix up the offsets of all SimTypeNumOffset fields to byte aligned addresses. Call this after replacing the fields of an arch-ed struct.

**Return type**
None

**Parameters**
**arch** (*Arch*)

c_repr(*name=None*, *full=0*, *memo=None*, *indent=0*, *name_parens=True*)

**Parameters**
**name_parens** (*bool*)

property size

The size of the type in bits, or None if no size is computable.

property alignment

The alignment of the type in bytes.

store(*state*, *addr*, *value*)

**Parameters**
**value** (*int | BV*)

copy()

class angr.sim_type.SimStructValue

Bases: object

A SimStruct type paired with some real values

__init__(*struct*, *values=None*)

**Parameters**

- **struct** – A SimStruct instance describing the type of this struct
- **values** – A mapping from struct fields to values

property struct

copy()

class angr.sim_type.SimUnion

Bases: *NamedTypeMixin*, *SimType*

fields = ('members', 'name')

__init__(*members*, *name=None*, *label=None*, *qualifier=None*)

**Parameters**

- **members** (dict[str, *SimType*]) – The members of the union, as a mapping name -> type
- **name** – The name of the union
- **qualifier** (*Iterable | None*)

property size

The size of the type in bits, or None if no size is computable.

property alignment

The alignment of the type in bytes.

extract(*state*, *addr*, *concrete=False*)

c_repr(*name=None*, *full=0*, *memo=None*, *indent=0*, *name_parens=True*)

**Parameters**

**name_parens** (*bool*)

copy()

class angr.sim_type.SimUnionValue

Bases: object

A SimStruct type paired with some real values

__init__(*union*, *values=None*)

**Parameters**

- **union** – A SimUnion instance describing the type of this union
- **values** – A mapping from union members to values

copy()

class angr.sim_type.SimTypeEnum

Bases: *NamedTypeMixin*, *SimType*

An enum type with named integer constants.

**Parameters**

- **members** (dict[str, int]) – A mapping from member names to their integer values.

- **base_type** (*SimType* | None) – The underlying integer type (default: SimTypeInt).
- **name** (str | None) – The name of the enum type.

**members:** dict[str, int]

**property base_type:** *SimType*

**property size:** int | None

The size of the type in bits, or None if no size is computable.

**property alignment**

The alignment of the type in bytes.

**resolve**(*value*)

Resolve an integer value to its enum member name.

**Parameters**
**value** (int) – The integer value to resolve.

**Return type**
str | None

**Returns**
The member name if found, None otherwise.

**c_repr**(*name=None*, *full=0*, *memo=None*, *indent=0*, *name_parens=True*)

**Parameters**
**name_parens** (*bool*)

**copy**()

**extract**(*state*, *addr*, *concrete=False*)

**store**(*state*, *addr*, *value*)

**class** angr.sim_type.**SimTypeBitfield**

Bases: *NamedTypeMixin*, *SimType*

A bitfield/flags type where values can be combinations of named bit flags.

This is useful for representing flags like PROT_READ | PROT_WRITE where multiple flags can be combined with bitwise OR.

**Parameters**

- **flags** (dict[str, int]) – A mapping from flag names to their bitmask values.
- **base_type** (*SimType* | None) – The underlying integer type (default: SimTypeInt).
- **name** (str | None) – The name of the bitfield type.

**flags:** dict[str, int]

**property base_type:** *SimType*

**property size:** int | None

The size of the type in bits, or None if no size is computable.

**property alignment**

The alignment of the type in bytes.

**resolve**(*value*)

Resolve an integer value to a combination of flag names.

**Parameters**
**value** (int) – The integer value to resolve.

**Return type**
tuple[list[str], int]

**Returns**
A tuple of (matched_flag_names, unknown_bits). If unknown_bits != 0, there are bits set that don't match any known flag.

**render**(*value*)

Render an integer value as a combination of flag names.

**Parameters**
**value** (int) – The integer value to render.

**Return type**
str

**Returns**
A string like "PROT_READ | PROT_WRITE" or "PROT_READ | PROT_WRITE | 0x100" if there are unknown bits.

**has_unknown_bits**(*value*)

Check if a value contains bits that don't match any known flag.

**Parameters**
**value** (int) – The integer value to check.

**Return type**
bool

**Returns**
True if there are unknown bits, False otherwise.

**validate**(*value*)

Check if a value contains only known flags.

**Parameters**
**value** (int) – The integer value to validate.

**Return type**
bool

**Returns**
True if all bits match known flags, False otherwise.

**c_repr**(*name=None*, *full=0*, *memo=None*, *indent=0*, *name_parens=True*)

**Parameters**
**name_parens** (*bool*)

**copy**()

**extract**(*state*, *addr*, *concrete=False*)

**store**(*state*, *addr*, *value*)

class angr.sim_type.**SimCppClass**

Bases: *SimStruct*

**property members**

**property size**

The size of the type in bits, or None if no size is computable.

**extract**(*state*, *addr*, *concrete=False*)

**Return type**
*SimCppClassValue*

**store**(*state*, *addr*, *value*)

**Parameters**
**value** (*int | BV*)

**copy**()

class angr.sim_type.**SimCppClassValue**

Bases: *SimStructValue*

A SimCppClass type paired with some real values

**copy**()

class angr.sim_type.**SimTypeNumOffset**

Bases: *SimTypeNum*

like SimTypeNum, but supports an offset of 1 to 7 to a byte aligned address to allow structs with bitfields

**extract**(*state*, *addr*, *concrete=False*)

**Overloads**

- **state** (), **addr**, **concrete** (Literal[False]) = ... → BV
- **state** (), **addr**, **concrete** (Literal[True]) → int

**Parameters**
**state** (SimState)

**store**(*state*, *addr*, *value*)

**copy**()

class angr.sim_type.**SimTypeRef**

Bases: *SimType*

SimTypeRef is a to-be-resolved reference to another SimType.

SimTypeRef is not SimTypeReference.

**property name:** str | None

**set_size**(*v*)

**Parameters**
**v** (*int*)

**c_repr**(*name=None*, *full=0*, *memo=None*, *indent=0*, *name_parens=True*)

**Return type**
str

**Parameters**
**name_parens** (*bool*)

angr.sim_type.**register_types**(*types*)

Pass in some types and they will be registered to the global type store.

The argument may be either a mapping from name to SimType, or a plain SimType. The plain SimType must be either a struct or union type with a name present.

```
>>> register_types(parse_types("typedef int x; typedef float y;"))
>>> register_types(parse_type("struct abcd { int ab; float cd; }"))
```

angr.sim_type.**parse_signature**(*defn*, *predefined_types=None*, *arch=None*)

Parse a single function prototype and return its type

**Return type**
*SimTypeFunction*

angr.sim_type.**parse_defns**(*defn*, *predefined_types=None*, *arch=None*)

Parse a series of C definitions, returns a mapping from variable name to variable type object

**Return type**
dict[str, *SimType*]

angr.sim_type.**parse_types**(*defn*, *predefined_types=None*, *arch=None*)

Parse a series of C definitions, returns a mapping from type name to type object

**Return type**
dict[str, *SimType*]

angr.sim_type.**parse_file**(*defn*, *predefined_types=None*, *arch=None*, *side_effect_types=None*)

Parse a series of C definitions, returns a tuple of two type mappings, one for variable definitions and one for type definitions.

**Return type**
tuple[dict[str, *SimType*], dict[str, *SimType*]]

**Parameters**

- **predefined_types** (*dict[Any, SimType] | None*)
- **side_effect_types** (*dict[Any, SimType] | None*)

angr.sim_type.**type_parser_singleton**()

**Return type**
CParser

angr.sim_type.**parse_type**(*defn*, *predefined_types=None*, *arch=None*)

Parse a simple type expression into a SimType

```
>>> parse_type('int *')
```

angr.sim_type.**parse_type_with_name**(*defn*, *preprocess=True*, *predefined_types=None*, *arch=None*, *side_effect_types=None*)

Parse a simple type expression into a SimType, returning a tuple of the type object and any associated name that might be found in the place a name would go in a type declaration.

```
>>> parse_type_with_name('int *foo')
```

**Parameters**

- **predefined_types** (*dict[Any, SimType] | None*)
- **side_effect_types** (*dict[Any, SimType] | None*)

angr.sim_type.**normalize_cpp_function_name**(*name*)

**Return type**
str

**Parameters**
**name** (*str*)

angr.sim_type.**parse_cpp_file**(*cpp_decl*, *with_param_names=False*)

**Parameters**
**with_param_names** (*bool*)

angr.sim_type.**mangled_long_double_as_double**(*proto*, *arch*)

Make each *long double* in a prototype parsed from an Itanium-mangled name a *double* where the mangling "e" means a plain double: on ARM, whose AAPCS long double is a double, and on s390x, where GCC mangles the 128-bit long double as "g" (__float128) and emits "e" only for -mlong-double-64 code (e.g., libstdc++'s compat symbols).

**Return type**
*SimTypeFunction*

**Parameters**

- **proto** (SimTypeFunction)
- **arch** (*Arch*)

## 10.41 angr.sim_variable

**class** angr.sim_variable.**SimVariable**

Bases: *Serializable*

The base class for all other classes of variables.

**__init__**(*size*, *ident=None*, *name=None*, *region=None*, *category=None*)

**Parameters**

- **ident** (str | None) – A unique identifier provided by user or the program. Usually a string.
- **name** (str | None) – Name of this variable.
- **size** (*int*)
- **region** (*int | None*)

ident

name

region: int | None

category: str | None

renamed

auto_renamed

candidate_names

size

copy()

Return type
Self

loc_repr(*arch*)

The representation that shows up in a GUI

Parameters
arch (*archinfo.Arch*)

property is_function_argument

property bits: int

property key: tuple[str | int | None, ...]

clear_hash()

class angr.sim_variable.SimConstantVariable

Bases: *SimVariable*

Describes a constant variable.

value

copy()

Return type
*SimConstantVariable*

property key: tuple[str | int | None, ...]

class angr.sim_variable.SimTemporaryVariable

Bases: *SimVariable*

Describes a temporary variable.

tmp_id

copy()

Return type
*SimTemporaryVariable*

property key: tuple[str | int | None, ...]

class angr.sim_variable.**SimRegisterVariable**

Bases: *SimVariable*

Describes a register variable.

**reg**

**property key:** tuple[str | int | None, ...]

**copy**()

**Return type**
*SimRegisterVariable*

class angr.sim_variable.**SimComboRegisterVariable**

Bases: *SimVariable*

A variable that spans multiple registers combined into a single value.

**reg_offsets**

**property bits**

**property key:** tuple[str | int | None, ...]

**copy**()

**Return type**
*SimComboRegisterVariable*

class angr.sim_variable.**SimMemoryVariable**

Bases: *SimVariable*

Describes a memory variable; the base class for other types of memory variables.

**addr**

**copy**()

**Return type**
*SimMemoryVariable*

**property key:** tuple[str | int | None, ...]

class angr.sim_variable.**SimStackVariable**

Bases: *SimMemoryVariable*

Describes a stack variable.

**base**

**offset**

**base_addr**

**copy**()

**Return type**
*SimStackVariable*

**property key:** tuple[str | int | None, ...]

## 10.42 angr.simos

Manage OS-level configuration.

**class** angr.simos.**SimCGC**

Bases: *SimUserland*

Environment configuration for the CGC DECREE platform

**__init__**(*project*, ***kwargs*)

**state_blank**(*flag_page=None*, *allocate_stack_page_count=256*, ***kwargs*)

**Parameters**

- **flag_page** – Flag page content, either a string or a list of BV8s
- **allocate_stack_page_count** – Number of pages to pre-allocate for stack

**state_entry**(*add_options=None*, ***kwargs*)

**class** angr.simos.**SimFreeBSD**

Bases: *SimUserland*

OS-specific configuration for FreeBSD.

FreeBSD is not Linux at the syscall boundary: above the handful of numbers both systems inherited from Research Unix it numbers its syscalls differently, and on i386 it takes their arguments from the stack rather than from registers.

**__init__**(*project*, ***kwargs*)

**class** angr.simos.**SimJavaVM**

Bases: *SimOS*

**__init__**(**args*, ***kwargs*)

**state_entry**(*args=None*, ***kwargs*)

Create an entry state.

**Parameters**

**args** – List of SootArgument values (optional).

**static generate_symbolic_cmd_line_arg**(*state*)

Generates a new symbolic cmd line argument string. :return: The string reference.

**state_call**(*addr*, **args*, ***kwargs*)

Create a native or a Java call state.

**Parameters**

- **addr** – Soot or native addr of the invoke target.
- **args** – List of SootArgument values.

**static get_default_value_by_type**(*type_*, *state*)

Java specify defaults values for primitive and reference types. This method returns the default value for a given type.

**Parameters**

- **type_** (*str*) – Name of type.

- **state** (SimState) – Current SimState.

**Returns**
Default value for this type.

**static cast_primitive**(*state*, *value*, *to_type*)

Cast the value of primitive types.

**Parameters**

- **value** – Bitvector storing the primitive value.
- **to_type** – Name of the targeted type.

**Returns**
Resized value.

**static init_static_field**(*state*, *field_class_name*, *field_name*, *field_type*)

Initialize the static field with an allocated, but not initialized, object of the given type.

**Parameters**

- **state** – State associated to the field.
- **field_class_name** – Class containing the field.
- **field_name** – Name of the field.
- **field_type** – Type of the field and the new object.

**static get_cmd_line_args**(*state*)

**get_addr_of_native_method**(*soot_method*)

Get address of the implementation from a native declared Java function.

**Parameters**
**soot_method** – Method descriptor of a native declared function.

**Returns**
CLE address of the given method.

**get_native_type**(*java_type*)

Maps the Java type to a SimTypeReg representation of its native counterpart. This type can be used to indicate the (well-defined) size of native JNI types.

**Returns**
A SymTypeReg with the JNI size of the given type.

**property native_arch**

Arch of the native simos.

**Type**
return

**get_native_cc**()

**Returns**
SimCC object for the native simos.

**class** angr.simos.**SimLinux**

Bases: *SimUserland*

OS-specific configuration for *nix-y OSes.

__init__(*project*, ***kwargs*)

state_entry(*args=None*, *env=None*, *argc=None*, ***kwargs*)

set_entry_register_values(*state*)

state_full_init(***kwargs*)

prepare_function_symbol(*symbol_name*, *basic_addr=None*)

Prepare the address space with the data necessary to perform relocations pointing to the given symbol.

Returns a 2-tuple. The first item is the address of the function code, the second is the address of the relocation target.

get_segment_register_name()

class angr.simos.SimOS

Bases: object

A class describing OS/arch-level configuration.

__init__(*project*, *name=None*)

**Parameters**

- **project** (Project)
- **name** (*str | None*)

name: str | None

configure_project()

Configure the project to set up global settings (like SimProcedures).

state_blank(*addr=None*, *initial_prefix=None*, *brk=None*, *stack_end=None*, *stack_size=8388608*, *stdin=None*, *thread_idx=None*, *permissions_backer=None*, ***kwargs*)

Initialize a blank state.

All parameters are optional.

**Parameters**

- **addr** – The execution start address.
- **initial_prefix**
- **stack_end** – The end of the stack (i.e., the byte after the last valid stack address).
- **stack_size** – The number of bytes to allocate for stack space
- **brk** – The address of the process' break.

**Returns**

The initialized SimState.

Any additional arguments will be passed to the SimState constructor

state_entry(***kwargs*)

state_full_init(***kwargs*)

state_call(*addr*, **args*, ***kwargs*)

**prepare_call_state**(*calling_state*, *initial_state=None*, *preserve_registers=()*, *preserve_memory=()*)

This function prepares a state that is executing a call instruction. If given an initial_state, it copies over all of the critical registers to it from the calling_state. Otherwise, it prepares the calling_state for action.

This is mostly used to create minimalistic for CFG generation. Some ABIs, such as MIPS PIE and x86 PIE, require certain information to be maintained in certain registers. For example, for PIE MIPS, this function transfer t9, gp, and ra to the new state.

**prepare_function_symbol**(*symbol_name*, *basic_addr=None*)

Prepare the address space with the data necessary to perform relocations pointing to the given symbol

Returns a 2-tuple. The first item is the address of the function code, the second is the address of the relocation target.

**handle_exception**(*successors*, *engine*, *exception*)

Perform exception handling. This method will be called when, during execution, a SimException is thrown. Currently, this can only indicate a segfault, but in the future it could indicate any unexpected exceptional behavior that can't be handled by ordinary control flow.

The method may mutate the provided SimSuccessors object in any way it likes, or re-raise the exception.

**Parameters**

- **successors** – The SimSuccessors object currently being executed on
- **engine** – The engine that was processing this step
- **exception** – The actual exception object

**syscall**(*state*, *allow_unsupported=True*)

**Return type**
*SimProcedure* | None

**Parameters**

- **state** (SimState)
- **allow_unsupported** (*bool*)

**syscall_abi**(*state*)

**Return type**
str | None

**Parameters**
**state** (SimState)

**syscall_cc**(*state*)

**Return type**
*SimCCSyscall* | None

**Parameters**
**state** (SimState)

**is_syscall_addr**(*addr*)

**Return type**
bool

**syscall_from_addr**(*addr*, *allow_unsupported=True*)

**Return type**
*SimProcedure* | None

**syscall_from_number**(*number*, *allow_unsupported=True*, *abi=None*)

**Return type**
*SimProcedure* | None

**setup_gdt**(*state*, *gdt*)

Write the GlobalDescriptorTable object in the current state memory

**Parameters**

- **state** – state in which to write the GDT
- **gdt** – GlobalDescriptorTable object

**Returns**

**generate_gdt**(*fs*, *gs*, *fs_size=4294967295*, *gs_size=4294967295*)

Generate a GlobalDescriptorTable object and populate it using the value of the gs and fs register

**Parameters**

- **fs** – value of the fs segment register
- **gs** – value of the gs segment register
- **fs_size** – size of the fs segment register
- **gs_size** – size of the gs segment register

**Returns**
gdt a GlobalDescriptorTable object

**class** angr.simos.**SimSnimmucNxp**

Bases: *SimOS*

This class implements the "OS" for a bare-metal firmware used at an imaginary company.

**__init__**(*project*, *name=None*, ***kwargs*)

**Parameters**
**project** (Project)

**class** angr.simos.**SimUefi**

Bases: *SimOS*

Environment for UEFI images. UEFI is a boot-time environment with no process model and no syscall interface, so what distinguishes it from a bare SimOS is its calling conventions: the x86 bindings of the UEFI specification adopt the Microsoft conventions rather than the System V ones, which is what DEFAULT_CC records for "UEFI".

**__init__**(*project*)

**class** angr.simos.**SimUserland**

Bases: *SimOS*

This is a base class for any SimOS that wants to support syscalls.

It uses the CLE kernel object to provide addresses for syscalls. Syscalls will be emulated as a jump to one of these addresses, where a SimProcedure from the syscall library provided at construction time will be executed.

**__init__**(*project*, *syscall_library=None*, *syscall_addr_alignment=4*, ***kwargs*)

**syscall_cc**(*state*)

**Return type**
*SimCCSyscall*

**syscall**(*state*, *allow_unsupported=True*)

Given a state, return the procedure corresponding to the current syscall. This procedure will have .syscall_number, .display_name, and .addr set.

**Parameters**

- **state** – The state to get the syscall number from
- **allow_unsupported** – Whether to return a "dummy" sycall instead of raising an unsupported exception

**syscall_abi**(*state*)

Optionally, override this function to determine which abi is being used for the state's current syscall.

**Return type**
str | None

**is_syscall_addr**(*addr*)

Return whether or not the given address corresponds to a syscall implementation.

**syscall_from_addr**(*addr*, *allow_unsupported=True*)

Get a syscall SimProcedure from an address.

**Parameters**

- **addr** – The address to convert to a syscall SimProcedure
- **allow_unsupported** – Whether to return a dummy procedure for an unsupported syscall instead of raising an exception.

**Returns**
The SimProcedure for the syscall, or None if the address is not a syscall address.

**syscall_from_number**(*number*, *allow_unsupported=True*, *abi=None*)

Get a syscall SimProcedure from its number.

**Parameters**

- **number** – The syscall number
- **allow_unsupported** – Whether to return a "stub" syscall for unsupported numbers instead of throwing an error
- **abi** – The name of the abi to use. If None, will assume that the abis have disjoint numbering schemes and pick the right one.

**Returns**
The SimProcedure for the syscall

**class** angr.simos.**SimWindows**

Bases: *SimOS*

Environment for the Windows Win32 subsystem. Does not support syscalls currently.

**__init__**(*project*)

property is_dump: bool

state_entry(*args=None*, *env=None*, *argc=None*, ***kwargs*)

syscall(*state*, *allow_unsupported=True*)

Given a state, return the procedure corresponding to the current syscall. This procedure will have .syscall_number, .display_name, and .addr set.

**Parameters**

- **state** – The state to get the syscall number from
- **allow_unsupported** – Whether to return a "dummy" sycall instead of raising an unsupported exception

is_syscall_addr(*addr*)

Return whether or not the given address corresponds to a syscall implementation.

syscall_from_addr(*addr*, *allow_unsupported=True*)

Get a syscall SimProcedure from an address.

**Parameters**

- **addr** – The address to convert to a syscall SimProcedure
- **allow_unsupported** – Whether to return a dummy procedure for an unsupported syscall instead of raising an exception.

**Returns**

The SimProcedure for the syscall, or None if the address is not a syscall address.

get_segment_register_name()

## 10.42.1 angr.simos.cgc

class angr.simos.cgc.SimCGC

Bases: *SimUserland*

Environment configuration for the CGC DECREE platform

__init__(*project*, ***kwargs*)

state_blank(*flag_page=None*, *allocate_stack_page_count=256*, ***kwargs*)

**Parameters**

- **flag_page** – Flag page content, either a string or a list of BV8s
- **allocate_stack_page_count** – Number of pages to pre-allocate for stack

**state_entry**(*add_options=None*, ***kwargs*)

### 10.42.2 angr.simos.freebsd

**class** angr.simos.freebsd.**SimFreeBSD**

Bases: *SimUserland*

OS-specific configuration for FreeBSD.

FreeBSD is not Linux at the syscall boundary: above the handful of numbers both systems inherited from Research Unix it numbers its syscalls differently, and on i386 it takes their arguments from the stack rather than from registers.

**__init__**(*project*, ***kwargs*)

### 10.42.3 angr.simos.javavm

**class** angr.simos.javavm.**SimJavaVM**

Bases: *SimOS*

**__init__**(**args*, ***kwargs*)

**state_entry**(*args=None*, ***kwargs*)

Create an entry state.

**Parameters**
**args** – List of SootArgument values (optional).

**static generate_symbolic_cmd_line_arg**(*state*)

Generates a new symbolic cmd line argument string. :return: The string reference.

**state_call**(*addr*, **args*, ***kwargs*)

Create a native or a Java call state.

**Parameters**

- **addr** – Soot or native addr of the invoke target.
- **args** – List of SootArgument values.

**static get_default_value_by_type**(*type_*, *state*)

Java specify defaults values for primitive and reference types. This method returns the default value for a given type.

**Parameters**

- **type_** (*str*) – Name of type.
- **state** (SimState) – Current SimState.

**Returns**
Default value for this type.

**static cast_primitive**(*state*, *value*, *to_type*)

Cast the value of primitive types.

**Parameters**

- **value** – Bitvector storing the primitive value.
- **to_type** – Name of the targeted type.

**Returns**
Resized value.

**static init_static_field**(*state*, *field_class_name*, *field_name*, *field_type*)

Initialize the static field with an allocated, but not initialized, object of the given type.

**Parameters**

- **state** – State associated to the field.
- **field_class_name** – Class containing the field.
- **field_name** – Name of the field.
- **field_type** – Type of the field and the new object.

**static get_cmd_line_args**(*state*)

**get_addr_of_native_method**(*soot_method*)

Get address of the implementation from a native declared Java function.

**Parameters**
**soot_method** – Method descriptor of a native declared function.

**Returns**
CLE address of the given method.

**get_native_type**(*java_type*)

Maps the Java type to a SimTypeReg representation of its native counterpart. This type can be used to indicate the (well-defined) size of native JNI types.

**Returns**
A SymTypeReg with the JNI size of the given type.

**property native_arch**

Arch of the native simos.

**Type**
return

**get_native_cc**()

**Returns**
SimCC object for the native simos.

angr.simos.javavm.**prepare_native_return_state**(*native_state*)

Hook target for native function call returns.

Recovers and stores the return value from native memory and toggles the state, s.t. execution continues in the Soot engine.

Note: Redirection needed for pickling.

### 10.42.4 angr.simos.linux

**class** angr.simos.linux.**SimLinux**

Bases: *SimUserland*

OS-specific configuration for *nix-y OSes.

**__init__**(*project*, ***kwargs*)

**state_entry**(*args=None*, *env=None*, *argc=None*, ***kwargs*)

**set_entry_register_values**(*state*)

**state_full_init**(***kwargs*)

**prepare_function_symbol**(*symbol_name*, *basic_addr=None*)

Prepare the address space with the data necessary to perform relocations pointing to the given symbol.

Returns a 2-tuple. The first item is the address of the function code, the second is the address of the relocation target.

**get_segment_register_name**()

### 10.42.5 angr.simos.simos

**class** angr.simos.simos.**SimOS**

Bases: object

A class describing OS/arch-level configuration.

**__init__**(*project*, *name=None*)

**Parameters**

- **project** (Project)
- **name** (*str | None*)

**name:** str | None

**configure_project**()

Configure the project to set up global settings (like SimProcedures).

**state_blank**(*addr=None*, *initial_prefix=None*, *brk=None*, *stack_end=None*, *stack_size=8388608*, *stdin=None*, *thread_idx=None*, *permissions_backer=None*, ***kwargs*)

Initialize a blank state.

All parameters are optional.

**Parameters**

- **addr** – The execution start address.
- **initial_prefix**
- **stack_end** – The end of the stack (i.e., the byte after the last valid stack address).
- **stack_size** – The number of bytes to allocate for stack space
- **brk** – The address of the process' break.

**Returns**

The initialized SimState.

Any additional arguments will be passed to the SimState constructor

**state_entry**(***kwargs*)

**state_full_init**(***kwargs*)

**state_call**(*addr*, **args*, ***kwargs*)

**prepare_call_state**(*calling_state*, *initial_state=None*, *preserve_registers=()*, *preserve_memory=()*)

This function prepares a state that is executing a call instruction. If given an initial_state, it copies over all of the critical registers to it from the calling_state. Otherwise, it prepares the calling_state for action.

This is mostly used to create minimalistic for CFG generation. Some ABIs, such as MIPS PIE and x86 PIE, require certain information to be maintained in certain registers. For example, for PIE MIPS, this function transfer t9, gp, and ra to the new state.

**prepare_function_symbol**(*symbol_name*, *basic_addr=None*)

Prepare the address space with the data necessary to perform relocations pointing to the given symbol

Returns a 2-tuple. The first item is the address of the function code, the second is the address of the relocation target.

**handle_exception**(*successors*, *engine*, *exception*)

Perform exception handling. This method will be called when, during execution, a SimException is thrown. Currently, this can only indicate a segfault, but in the future it could indicate any unexpected exceptional behavior that can't be handled by ordinary control flow.

The method may mutate the provided SimSuccessors object in any way it likes, or re-raise the exception.

**Parameters**

- **successors** – The SimSuccessors object currently being executed on
- **engine** – The engine that was processing this step
- **exception** – The actual exception object

**syscall**(*state*, *allow_unsupported=True*)

**Return type**
*SimProcedure* | None

**Parameters**

- **state** (SimState)
- **allow_unsupported** (*bool*)

**syscall_abi**(*state*)

**Return type**
str | None

**Parameters**
**state** (SimState)

**syscall_cc**(*state*)

**Return type**
*SimCCSyscall* | None

**Parameters**
**state** (SimState)

**is_syscall_addr**(*addr*)

**Return type**
bool

**syscall_from_addr**(*addr*, *allow_unsupported=True*)

**Return type**
*SimProcedure* | None

**syscall_from_number**(*number*, *allow_unsupported=True*, *abi=None*)

**Return type**
*SimProcedure* | None

**setup_gdt**(*state*, *gdt*)

Write the GlobalDescriptorTable object in the current state memory

**Parameters**

- **state** – state in which to write the GDT
- **gdt** – GlobalDescriptorTable object

**Returns**

**generate_gdt**(*fs*, *gs*, *fs_size=4294967295*, *gs_size=4294967295*)

Generate a GlobalDescriptorTable object and populate it using the value of the gs and fs register

**Parameters**

- **fs** – value of the fs segment register
- **gs** – value of the gs segment register
- **fs_size** – size of the fs segment register
- **gs_size** – size of the gs segment register

**Returns**
gdt a GlobalDescriptorTable object

**class** angr.simos.simos.**GlobalDescriptorTable**

Bases: object

GlobalDescriptorTable object to store the GDT table and the segment registers values

**__init__**(*addr*, *limit*, *table*, *gdt_sel*, *cs_sel*, *ds_sel*, *es_sel*, *ss_sel*, *fs_sel*, *gs_sel*)

### 10.42.6 angr.simos.snimmuc_nxp

**class** angr.simos.snimmuc_nxp.**SimSnimmucNxp**

Bases: *SimOS*

This class implements the "OS" for a bare-metal firmware used at an imaginary company.

**__init__**(*project*, *name=None*, ***kwargs*)

**Parameters**
**project** (Project)

### 10.42.7 angr.simos.uefi

class angr.simos.uefi.**SimUefi**

Bases: *SimOS*

Environment for UEFI images. UEFI is a boot-time environment with no process model and no syscall interface, so what distinguishes it from a bare SimOS is its calling conventions: the x86 bindings of the UEFI specification adopt the Microsoft conventions rather than the System V ones, which is what DEFAULT_CC records for "UEFI".

**__init__**(*project*)

### 10.42.8 angr.simos.userland

class angr.simos.userland.**SimUserland**

Bases: *SimOS*

This is a base class for any SimOS that wants to support syscalls.

It uses the CLE kernel object to provide addresses for syscalls. Syscalls will be emulated as a jump to one of these addresses, where a SimProcedure from the syscall library provided at construction time will be executed.

**__init__**(*project*, *syscall_library=None*, *syscall_addr_alignment=4*, ***kwargs*)

**syscall_cc**(*state*)

**Return type**
*SimCCSyscall*

**syscall**(*state*, *allow_unsupported=True*)

Given a state, return the procedure corresponding to the current syscall. This procedure will have .syscall_number, .display_name, and .addr set.

**Parameters**

- **state** – The state to get the syscall number from
- **allow_unsupported** – Whether to return a "dummy" sycall instead of raising an unsupported exception

**syscall_abi**(*state*)

Optionally, override this function to determine which abi is being used for the state's current syscall.

**Return type**
str | None

**is_syscall_addr**(*addr*)

Return whether or not the given address corresponds to a syscall implementation.

**syscall_from_addr**(*addr*, *allow_unsupported=True*)

Get a syscall SimProcedure from an address.

**Parameters**

- **addr** – The address to convert to a syscall SimProcedure
- **allow_unsupported** – Whether to return a dummy procedure for an unsupported syscall instead of raising an exception.

**Returns**
The SimProcedure for the syscall, or None if the address is not a syscall address.

**syscall_from_number**(*number*, *allow_unsupported=True*, *abi=None*)

Get a syscall SimProcedure from its number.

**Parameters**

- **number** – The syscall number
- **allow_unsupported** – Whether to return a "stub" syscall for unsupported numbers instead of throwing an error
- **abi** – The name of the abi to use. If None, will assume that the abis have disjoint numbering schemes and pick the right one.

**Returns**

The SimProcedure for the syscall

### 10.42.9 angr.simos.windows

**class** angr.simos.windows.**SecurityCookieInit**

Bases: Enum

Security cooke initialization value initialization method.

**NONE = 0**

**RANDOM = 1**

**STATIC = 2**

**SYMBOLIC = 3**

**class** angr.simos.windows.**SimWindows**

Bases: *SimOS*

Environment for the Windows Win32 subsystem. Does not support syscalls currently.

**__init__**(*project*)

**property is_dump: bool**

**state_entry**(*args=None*, *env=None*, *argc=None*, ***kwargs*)

**syscall**(*state*, *allow_unsupported=True*)

Given a state, return the procedure corresponding to the current syscall. This procedure will have .syscall_number, .display_name, and .addr set.

**Parameters**

- **state** – The state to get the syscall number from
- **allow_unsupported** – Whether to return a "dummy" sycall instead of raising an unsupported exception

**is_syscall_addr**(*addr*)

Return whether or not the given address corresponds to a syscall implementation.

**syscall_from_addr**(*addr*, *allow_unsupported=True*)

Get a syscall SimProcedure from an address.

**Parameters**

- **addr** – The address to convert to a syscall SimProcedure

- **allow_unsupported** – Whether to return a dummy procedure for an unsupported syscall instead of raising an exception.

**Returns**
The SimProcedure for the syscall, or None if the address is not a syscall address.

**get_segment_register_name**()

### 10.42.10 angr.simos.xbox

**class** angr.simos.xbox.**SimXbox**

Bases: *SimOS*

Environment for the original Xbox subsystem (x86, 32-bit).

**__init__**(*project*)

## 10.43 angr.slicer

**class** angr.slicer.**SimLightState**

Bases: object

Represents a program state. Only used in SimSlicer.

**__init__**(*temps=None*, *regs=None*, *stack_offsets=None*, *options=None*)

**temps**

**regs**

**stack_offsets**

**options**

**class** angr.slicer.**SimSlicer**

Bases: object

A super lightweight intra-IRSB slicing class.

**__init__**(*arch*, *statements*, *target_tmps=None*, *target_regs=None*, *target_stack_offsets=None*, *inslice_callback=None*, *inslice_callback_infodict=None*, *include_imarks=True*)

**Parameters**
**include_imarks** (*bool*)

## 10.44 angr.state_hierarchy

**class** angr.state_hierarchy.**StateHierarchy**

Bases: object

The state hierarchy holds weak references to SimStateHistory objects in a directed acyclic graph. It is useful for queries about a state's ancestry, notably "what is the best ancestor state for a merge among these states" and "what is the most recent unsatisfiable state while using LAZY_SOLVES"

**__init__**()

**get_ref**(*obj*)

**dead_ref**(*ref*)

**defer_cleanup**()

**add_state**(*s*)

**add_history**(*h*)

**simplify**()

**full_simplify**()

**lineage**(*h*)

Returns the lineage of histories leading up to *h*.

**all_successors**(*h*)

**history_successors**(*h*)

**history_predecessors**(*h*)

**history_contains**(*h*)

**unreachable_state**(*state*)

**unreachable_history**(*h*)

**most_mergeable**(*states*)

Find the "most mergeable" set of states from those provided.

**Parameters**
**states** – a list of states

**Returns**
a tuple of: (list of states to merge, those states' common history, list of states to not merge yet)

## 10.45 angr.state_plugins

angr.state_plugins.**BP_IPDB**(*state*)

**Return type**
None

**Parameters**
**state** (SimState)

angr.state_plugins.**BP_IPYTHON**(*state*)

**Return type**
None

**Parameters**
**state** (SimState)

**class** angr.state_plugins.**GDB**

Bases: *SimStatePlugin*

Initialize or update a state from gdb dumps of the stack, heap, registers and data (or arbitrary) segments.

__init__(*omit_fp=False*, *adjust_stack=False*)

**Parameters**

- **omit_fp** – The frame pointer register is used for something else. (i.e. –omit_frame_pointer)
- **adjust_stack** – Use different stack addresses than the gdb session (not recommended).

set_stack(*stack_dump*, *stack_top*)

Stack dump is a dump of the stack from gdb, i.e. the result of the following gdb command :

`dump binary memory [stack_dump] [begin_addr] [end_addr]`

We set the stack to the same addresses as the gdb session to avoid pointers corruption.

**Parameters**

- **stack_dump** – The dump file.
- **stack_top** – The address of the top of the stack in the gdb session.

set_heap(*heap_dump*, *heap_base*)

Heap dump is a dump of the heap from gdb, i.e. the result of the following gdb command:

`dump binary memory [stack_dump] [begin] [end]`

**Parameters**

- **heap_dump** – The dump file.
- **heap_base** – The start address of the heap in the gdb session.

set_data(*addr*, *data_dump*)

Update any data range (most likely use is the data segments of loaded objects)

set_regs(*regs_dump*)

Initialize register values within the state

**Parameters**
**regs_dump** – The output of `info registers` in gdb.

class angr.state_plugins.**CallStack**

Bases: *SimStatePlugin*

Stores the address of the function you're in and the value of SP at the VERY BOTTOM of the stack, i.e. points to the return address.

__init__(*call_site_addr=0*, *func_addr=0*, *stack_ptr=0*, *ret_addr=0*, *jumpkind='Ijk_Call'*, *next_frame=None*, *invoke_return_variable=None*)

**Parameters**
**next_frame** (*Self | None*)

copy_without_tail(*memo*)

property current_function_address

Address of the current function.

**Returns**
the address of the function

**Return type**
int

**property current_stack_pointer**

Get the value of the stack pointer.

**Returns**
Value of the stack pointer

**Return type**
int

**property current_return_target**

Get the return target.

**Returns**
The address of return target.

**Return type**
int

**static stack_suffix_to_string**(*stack_suffix*)

Convert a stack suffix to a human-readable string representation. :type stack_suffix: tuple :param stack_suffix: The stack suffix. :return: A string representation :rtype: str

**property top: Self**

Returns the element at the top of the callstack without removing it.

**Returns**
A CallStack.

**push**(*cf*)

Push the frame cf onto the stack. Return the new stack.

**Return type**
Self

**Parameters**
**cf** (*Self*)

**pop**()

Pop the top frame from the stack. Return the new stack.

**call**(*callsite_addr*, *addr*, *retn_target=None*, *stack_pointer=None*)

Push a stack frame into the call stack. This method is called when calling a function in CFG recovery.

**Parameters**

- **callsite_addr** (*int*) – Address of the call site
- **addr** (*int*) – Address of the call target
- **retn_target** (*int or None*) – Address of the return target
- **stack_pointer** (*int*) – Value of the stack pointer

**Returns**
None

**ret**(*retn_target=None*)

Pop one or many call frames from the stack. This method is called when returning from a function in CFG recovery.

**Parameters**
**retn_target** (*int*) – The target to return to.

**Returns**
None

**dbg_repr**()

Debugging representation of this CallStack object.

**Returns**
Details of this CalLStack

**Return type**
str

**stack_suffix**(*context_sensitivity_level*)

Generate the stack suffix. A stack suffix can be used as the key to a SimRun in CFG recovery.

**Parameters**
**context_sensitivity_level** (*int*) – Level of context sensitivity.

**Returns**
A tuple of stack suffix.

**Return type**
tuple[int | None, ...]

**class** angr.state_plugins.**InspectAttrs**

Bases: object

Per-event attributes published by the inspect machinery while a breakpoint is firing.

Each field is set on the active state before any matching breakpoint is checked, then cleared (back to None) after the event completes. Breakpoint actions read and write these fields through state.inspect.attrs to observe or override the in-flight event.

**Return type**
None

**class** angr.state_plugins.**PTChunk**

Bases: *Chunk*

A chunk, inspired by the implementation of chunks in ptmalloc. Provides a representation of a chunk via a view into the memory plugin. For the chunk definitions and docs that this was loosely based off of, see glibc malloc/malloc.c, line 1033, as of commit 5a580643111ef6081be7b4c7bd1997a5447c903f. Alternatively, take the following link. https://sourceware.org/git/?p=glibc.git;a=blob;f=malloc/malloc.c;h=67cdfd0ad2f003964cd0f7dfe3bcd85ca98528a7;hb=5a580643111ef6081be7b4c7bd1997a5447c903f#l1033

**Variables**

- **base** – the location of the base of the chunk in memory
- **state** – the program state that the chunk is resident in
- **heap** – the heap plugin that the chunk is managed by

**__init__**(*base*, *sim_state*, *heap=None*)

**set_size**(*size*, *is_free=None*)

Use this to set the size on a chunk. When the chunk is new (such as when a free chunk is shrunk to form an allocated chunk and a remainder free chunk) it is recommended that the is_free hint be used since setting the size depends on the chunk's freeness, and vice versa.

**Parameters**

- **size** – size of the chunk

- **is_free** – boolean indicating the chunk's freeness

**set_prev_freeness**(*is_free*)

Sets (or unsets) the flag controlling whether the previous chunk is free.

**Parameters**
**is_free** – if True, sets the previous chunk to be free; if False, sets it to be allocated

**is_prev_free**()

Returns a concrete state of the flag indicating whether the previous chunk is free or not. Issues a warning if that flag is symbolic and has multiple solutions, and then assumes that the previous chunk is free.

**Returns**
True if the previous chunk is free; False otherwise

**prev_size**()

Returns the size of the previous chunk, masking off what would be the flag bits if it were in the actual size field. Performs NO CHECKING to determine whether the previous chunk size is valid (for example, when the previous chunk is not free, its size cannot be determined).

**next_chunk**()

Returns the chunk immediately following (and adjacent to) this one, if it exists.

**Returns**
The following chunk, or None if applicable

**prev_chunk**()

Returns the chunk immediately prior (and adjacent) to this one, if that chunk is free. If the prior chunk is not free, then its base cannot be located and this method raises an error.

**Returns**
If possible, the previous chunk; otherwise, raises an error

**fwd_chunk**()

Returns the chunk following this chunk in the list of free chunks. If this chunk is not free, then it resides in no such list and this method raises an error.

**Returns**
If possible, the forward chunk; otherwise, raises an error

**bck_chunk**()

Returns the chunk backward from this chunk in the list of free chunks. If this chunk is not free, then it resides in no such list and this method raises an error.

**Returns**
If possible, the backward chunk; otherwise, raises an error

**class** angr.state_plugins.**PTChunkIterator**

Bases: object

**__init__**(*chunk*, *cond=<function PTChunkIterator.<lambda>>*)

**class** angr.state_plugins.**PosixDevFS**

Bases: *SimMount*

**class** angr.state_plugins.**PosixProcFS**

Bases: *SimMount*

The virtual file system mounted at /proc (as of now, on Linux).

class angr.state_plugins.**SimAction**

Bases: *SimEvent*

A SimAction represents a semantic action that an analyzed program performs.

**TMP = 'tmp'**

**REG = 'reg'**

**MEM = 'mem'**

**__init__**(*state*, *region_type*)

Initializes the SimAction.

**Parameters**

**state** – the state that's the SimAction is taking place in.

**property all_objects**

**property is_symbolic**

**property tmp_deps**

**property reg_deps**

**copy**()

**downsize**()

Clears some low-level details (that take up memory) out of the SimAction.

class angr.state_plugins.**SimActionConstraint**

Bases: *SimAction*

A constraint action represents an extra constraint added during execution of a path.

**property all_objects**

**property is_symbolic**

class angr.state_plugins.**SimActionData**

Bases: *SimAction*

A Data action represents a read or a write from memory, registers or a file.

**READ = 'read'**

**WRITE = 'write'**

**OPERATE = 'operate'**

**property all_objects**

**property is_symbolic**

**property tmp_deps**

**property reg_deps**

**property storage**

class angr.state_plugins.**SimActionExit**

Bases: *SimAction*

An Exit action represents a (possibly conditional) jump.

**CONDITIONAL = 'conditional'**

**DEFAULT = 'default'**

**property all_objects**

**property is_symbolic**

class angr.state_plugins.**SimActionObject**

Bases: object

A SimActionObject tracks an AST and its dependencies.

**__init__**(*ast*, *reg_deps=frozenset({})*, *tmp_deps=frozenset({})*, *deps=frozenset({})*, *state=None*)

**Parameters**

- **ast** (*claripy.ast.Base*)
- **reg_deps** (*frozenset[SimActionData | SimActionOperation]*)
- **tmp_deps** (*frozenset[SimActionData | SimActionOperation]*)
- **deps** (*frozenset*)
- **state** (*SimState | None*)

**ast: Base**

**reg_deps: frozenset[*SimActionData* | *SimActionOperation*]**

**tmp_deps: frozenset[*SimActionData* | *SimActionOperation*]**

**to_claripy**()

**Return type**
Base

**copy**()

**Return type**
*SimActionObject*

**is_leaf**()

**Return type**
bool

**property op: str**

**property args: tuple[ArgType, ...]**

**property length: int | None**

**property variables: frozenset[str]**

**property symbolic: bool**

property annotations: tuple[Annotation, ...]

property depth: int

SDiv(*other*)

**Return type**
*SimActionObject*

SMod(*other*)

**Return type**
*SimActionObject*

union(*other*)

**Return type**
*SimActionObject*

intersection(*other*)

**Return type**
*SimActionObject*

widen(*other*)

**Return type**
*SimActionObject*

raw_to_bv()

**Return type**
*SimActionObject*

bv_to_fp()

**Return type**
*SimActionObject*

class angr.state_plugins.SimActionOperation

Bases: *SimAction*

An action representing an operation between variables and/or constants.

property all_objects

property is_symbolic

class angr.state_plugins.SimDebugVariable

Bases: object

A SimDebugVariable will get dynamically created when queriyng for variable in a state with the SimDebugVariablePlugin. It features a link to the state, an address and a type.

__init__(*state*, *addr*, *var_type*)

**Parameters**

- **state** (SimState)
- **var_type** (*VariableType*)

**static from_cle_variable**(*state*, *cle_variable*, *dwarf_cfa*)

**Return type**
*SimDebugVariable*

**Parameters**

- **state** (SimState)
- **cle_variable** (*Variable*)

**property mem_untyped:** *SimMemView*

**property mem:** *SimMemView*

**property string:** *SimMemView*

**with_type**(*sim_type*)

**Return type**
*SimMemView*

**Parameters**
**sim_type** (SimType)

**property resolvable**

**property resolved**

**property concrete**

**store**(*value*)

**property deref:** *SimDebugVariable*

**array**(*i*)

**Return type**
*SimDebugVariable*

**member**(*member_name*)

**Return type**
*SimDebugVariable*

**Parameters**
**member_name** (*str*)

**class** angr.state_plugins.**SimDebugVariablePlugin**

Bases: *SimStatePlugin*

This is the plugin you'll use to interact with (global/local) program variables. These variables have a name and a visibility scope which depends on the pc address of the state. With this plugin, you can access/modify the value of such variable or find its memory address. For creating program variables, or for importing them from cle, see the knowledge plugin debug_variables. Run `p.kb.dvars.load_from_dwarf()` before using this plugin.

### Example

```
>>> p = angr.Project("various_variables", load_debug_info=True)
>>> p.kb.dvars.load_from_dwarf()
>>> state =  # navigate to the state you want
>>> state.dvars.get_variable("pointer2").deref.mem
<int (32 bits) <BV32 0x1> at 0x404020>
```

**get_variable**(*var_name*)

Returns the visible variable (if any) with name `var_name` based on the current `state.ip`.

**Return type**
*SimDebugVariable*

**Parameters**
**var_name** (*str*)

**property dwarf_cfa**

Returns the current cfa computation. Set this property to the correct value if needed.

**property dwarf_cfa_approx**

**class** angr.state_plugins.**SimEvent**

Bases: object

A SimEvent is a log entry for some notable event during symbolic execution. It logs the location it was generated (ins_addr, bbl_addr, stmt_idx, and sim_procedure) as well as arbitrary tags (objects).

You may also be interested in SimAction, which is a specialization of SimEvent for CPU events.

**__init__**(*state*, *event_type*, ***kwargs*)

**class** angr.state_plugins.**SimFilesystem**

Bases: *SimStatePlugin*

angr's emulated filesystem. Available as state.fs. When constructing, all parameters are optional.

**Parameters**

- **files** – A mapping from filepath to SimFile
- **pathsep** – The character used to separate path elements, default forward slash.
- **cwd** – The path of the current working directory to use
- **mountpoints** – A mapping from filepath to SimMountpoint

**Variables**

- **pathsep** – The current pathsep
- **cwd** – The current working directory, relative to the current root
- **unlinks** – A list of unlink operations, tuples of filename and simfile. Be careful, this list is shallow-copied from successor to successor, so don't mutate anything in it without copying.

**__init__**(*files=None*, *pathsep=None*, *cwd=None*, *mountpoints=None*)

**property unlinks**

**property root**

The current root directory, as an absolute path in the filesystem's original namespace, i.e. the one paths were resolved in before any chroot.

**chdir**(*path*)

Changes the current directory to the given path

**chroot**(*path*)

Changes the root directory to the given path, which is interpreted relative to the current root.

This only ever narrows what is reachable: the new root is resolved inside this filesystem, and paths (including "..") are resolved under it from then on. Contrary to Linux, where the current directory is left where it was and can therefore point outside the new root, the current directory is re-anchored inside the new root, since keeping it outside would defeat the point.

**get**(*path*)

Get a file from the filesystem. Returns a SimFile or None.

**insert**(*path*, *simfile*)

Insert a file into the filesystem. Returns whether the operation was successful.

**delete**(*path*)

Remove a file from the filesystem. Returns whether the operation was successful.

This will add a `fs_unlink` event with the path of the file and also the index into the *unlinks* list.

**mount**(*path*, *mount*)

Add a mountpoint to the filesystem.

**unmount**(*path*)

Remove a mountpoint from the filesystem.

**get_mountpoint**(*path*)

Look up the mountpoint servicing the given path.

**Returns**

A tuple of the mount and a list of path elements traversing from the mountpoint to the specified file. If no mountpoint services the path, the list traverses from the real root instead.

**class** angr.state_plugins.**SimHeapBase**

Bases: *SimStatePlugin*

This is the base heap class that all heap implementations should subclass. It defines a few handlers for common heap functions (the libc memory management functions). Heap implementations are expected to override these functions regardless of whether they implement the SimHeapLibc interface. For an example, see the SimHeapBrk implementation, which is based on the original libc SimProcedure implementations.

**Variables**

- **heap_base** – the address of the base of the heap in memory
- **heap_size** – the maximum size of the main memory region managed by the heap in memory. Only the part of it that has actually been handed out is mapped; see `_ensure_mapped`.
- **mmap_base** – the address of the region from which large mmap allocations will be made

**__init__**(*heap_base=None*, *heap_size=None*)

**class** angr.state_plugins.**SimHeapBrk**

Bases: *SimHeapBase*

SimHeapBrk represents a trivial heap implementation based on the Unix *brk* system call. This type of heap stores virtually no metadata, so it is up to the user to determine when it is safe to release memory. This also means that it does not properly support standard heap operations like *realloc*.

This heap implementation is a holdover from before any more proper implementations were modelled. At the time, various libc (or win32) SimProcedures handled the heap in the same way that this plugin does now. To make future heap implementations plug-and-playable, they should implement the necessary logic themselves, and dependent SimProcedures should invoke a method by the same name as theirs (prepended with an underscore) upon the heap plugin. Depending on the heap implementation, if the method is not supported, an error should be raised.

Out of consideration for the original way the heap was handled, this plugin implements functionality for all relevant SimProcedures (even those that would not normally be supported together in a single heap implementation).

**Variables**
**heap_location** – the address of the top of the heap, bounding the allocations made starting from *heap_base*

**__init__**(*heap_base=None*, *heap_size=None*)

**allocate**(*sim_size*)

The actual allocation primitive for this heap implementation. Increases the position of the break to allocate space. Has no guards against the heap growing too large.

**Parameters**
**sim_size** – a size specifying how much to increase the break pointer by

**Returns**
a pointer to the previous break position, above which there is now allocated space

**release**(*sim_size*)

The memory release primitive for this heap implementation. Decreases the position of the break to deallocate space. Guards against releasing beyond the initial heap base.

The mapped extent of the heap is deliberately not shrunk here. Unmapping the released pages would discard their contents, so a release followed by an allocation would hand back blank memory instead of the old bytes, which is a behavior change; and since the extent only ever grows to the high-water mark of the break, keeping it costs nothing beyond what the program already asked for.

**Parameters**
**sim_size** – a size specifying how much to decrease the break pointer by (may be symbolic or not)

**class** angr.state_plugins.**SimHeapLibc**

Bases: *SimHeapBase*

A class of heap that implements the major libc heap management functions.

**malloc**(*sim_size*)

A somewhat faithful implementation of libc *malloc*.

**Parameters**
**sim_size** – the amount of memory (in bytes) to be allocated

**Returns**
the address of the allocation, or a NULL pointer if the allocation failed

**free**(*ptr*)

A somewhat faithful implementation of libc *free*.

**Parameters**
**ptr** – the location in memory to be freed

**calloc**(*sim_nmemb*, *sim_size*)

A somewhat faithful implementation of libc *calloc*.

**Parameters**

- **sim_nmemb** – the number of elements to allocated
- **sim_size** – the size of each element (in bytes)

**Returns**
the address of the allocation, or a NULL pointer if the allocation failed

**realloc**(*ptr*, *size*)

A somewhat faithful implementation of libc *realloc*.

**Parameters**

- **ptr** – the location in memory to be reallocated
- **size** – the new size desired for the allocation

**Returns**
the address of the allocation, or a NULL pointer if the allocation was freed or if no new allocation was made

**class** angr.state_plugins.**SimHeapPTMalloc**

Bases: *SimHeapFreelist*

A freelist-style heap implementation inspired by ptmalloc. The chunks used by this heap contain heap metadata in addition to user data. While the real-world ptmalloc is implemented using multiple lists of free chunks (corresponding to their different sizes), this more basic model uses a single list of chunks and searches for free chunks using a first-fit algorithm.

**NOTE:** The plugin must be registered using `register_plugin` with name `heap` in order to function properly.

**Variables**

- **heap_base** – the address of the base of the heap in memory
- **heap_size** – the total size of the main memory region managed by the heap in memory
- **mmap_base** – the address of the region from which large mmap allocations will be made
- **free_head_chunk** – the head of the linked list of free chunks in the heap

**__init__**(*heap_base=None*, *heap_size=None*)

**chunk_from_mem**(*ptr*)

Given a pointer to a user payload, return the base of the chunk associated with that payload (i.e. the chunk pointer). Returns None if ptr is null.

**Parameters**
**ptr** – a pointer to the base of a user payload in the heap

**Returns**
a pointer to the base of the associated heap chunk, or None if ptr is null

**class** angr.state_plugins.**SimHostFilesystem**

Bases: *SimConcreteFilesystem*

Simulated mount that makes some piece from the host filesystem available to the guest.

**Parameters**

- **host_path** (*str*) – The path on the host to mount

- **pathsep** (*str*) – The host path separator character, default os.path.sep

**__init__**(*host_path=None*, ***kwargs*)

**class** angr.state_plugins.**SimInspector**

Bases: *SimStatePlugin*

The breakpoint interface, used to instrument execution. For usage information, look here: https://docs.angr.io/core-concepts/simulation#breakpoints

**BP_AFTER = 'after'**

**BP_BEFORE = 'before'**

**BP_BOTH = 'both'**

**__init__**()

**action**(*event_type*, *when*, ***kwargs*)

Called from within the engine when events happens. This function checks all breakpoints registered for that event and fires the ones whose conditions match.

**Return type**
None

**Parameters**

- **event_type** (EventType)
- **when** (When)
- **kwargs** (*dict[str, Any]*)

**make_breakpoint**(*event_type*, *when=When.BEFORE*, *enabled=True*, *condition=None*, *action=<function BP_IPDB>*, ***kwargs*)

Creates and adds a breakpoint which would trigger on *event_type*. Additional arguments are passed to the BP constructor.

**Returns**
The created breakpoint, so that it can be removed later.

**Parameters**

- **event_type** (EventType)
- **when** (When)
- **enabled** (*bool*)
- **condition** (*Callable[[SimState], bool] | None*)
- **action** (Action)
- **kwargs** (*dict[str, Any]*)

**b**(*event_type*, *when=When.BEFORE*, *enabled=True*, *condition=None*, *action=<function BP_IPDB>*, ***kwargs*)

Creates and adds a breakpoint which would trigger on *event_type*. Additional arguments are passed to the BP constructor.

**Returns**
The created breakpoint, so that it can be removed later.

**Parameters**

- **event_type** (EventType)
- **when** (When)
- **enabled** (*bool*)
- **condition** (*Callable[[SimState], bool] | None*)
- **action** (Action)
- **kwargs** (*dict[str, Any]*)

**add_breakpoint**(*event_type*, *bp*)

Adds a breakpoint which would trigger on *event_type*.

**Parameters**

- **event_type** (*EventType*) – The event type to trigger on
- **bp** (*BP*) – The breakpoint

**Return type**
None

**Returns**
The created breakpoint.

**remove_breakpoint**(*event_type*, *bp=None*, *filter_func=None*)

Removes a breakpoint.

**Parameters**

- **bp** (*BP* | None) – The breakpoint to remove.
- **filter_func** (Callable[[*BP*], bool] | None) – A filter function to specify whether each breakpoint should be removed or not.
- **event_type** (EventType)

**Return type**
None

**downsize**()

Reset event-specific attributes on this plugin instance to save memory. This method is supposed to be called by breakpoint implementors. A typical workflow looks like the following:

```
>>> # Add `attr0` and `attr1` via the inspect machinery
>>> self.state.inspect(xxxxxx, attr0=yyyy, attr1=zzzz)
>>> # Get new attributes out of SimInspect in case they are modified by the user
>>> new_attr0 = self.state.inspect.attrs.attr0
>>> new_attr1 = self.state.inspect.attrs.attr1
>>> # Reset them
>>> self.state.inspect.downsize()
```

**class** angr.state_plugins.**SimJavaVmClassloader**

Bases: *SimStatePlugin*

JavaVM Classloader is used as an interface for resolving and initializing Java classes.

**__init__**(*initialized_classes=None*)

**get_class**(*class_name*, *init_class=False*, *step_func=None*)

Get a class descriptor for the class.

**Parameters**

- **class_name** (*str*) – Name of class.
- **init_class** (*bool*) – Whether the class initializer <clinit> should be executed.
- **step_func** (*func*) – Callback function executed at every step of the simulation manager during the execution of the main <clinit> method

**get_superclass**(*class_*)

Get the superclass of the class.

**get_class_hierarchy**(*base_class*)

Walks up the class hierarchy and returns a list of all classes between base class (inclusive) and java.lang.Object (exclusive).

**is_class_initialized**(*class_*)

Indicates whether the classes initializing method <clinit> was already executed on the state.

**init_class**(*class_*, *step_func=None*)

This method simulates the loading of a class by the JVM, during which parts of the class (e.g. static fields) are initialized. For this, we run the class initializer method <clinit> (if available) and update the state accordingly.

**Note: Initialization is skipped, if the class has already been initialized (or if it's not loaded in CLE).**

**property initialized_classes**

List of all initialized classes.

**class** angr.state_plugins.**SimLightRegisters**

Bases: *SimStatePlugin*

**__init__**(*reg_map=None*, *registers=None*)

**resolve_register**(*offset*, *size*)

**load**(*offset*, *size=None*, ***kwargs*)

**store**(*offset*, *value*, *size=None*, *endness=None*, ***kwargs*)

**class** angr.state_plugins.**SimMemView**

Bases: *SimStatePlugin*

This is a convenient interface with which you can access a program's memory.

The interface works like this:

- You first use [array index notation] to specify the address you'd like to load from
- If at that address is a pointer, you may access the `deref` property to return a SimMemView at the address present in memory.
- You then specify a type for the data by simply accessing a property of that name. For a list of supported types, look at `state.mem.types`.
- You can then *refine* the type. Any type may support any refinement it likes. Right now the only refinements supported are that you may access any member of a struct by its member name, and you may index into a string or array to access that element.

- If the address you specified initially points to an array of that type, you can say *.array(n)* to view the data as an array of n elements.
- Finally, extract the structured data with `.resolved` or `.concrete`. `.resolved` will return bitvector values, while `.concrete` will return integer, string, array, etc values, whatever best represents the data.
- Alternately, you may store a value to memory, by assigning to the chain of properties that you've constructed. Note that because of the way python works, `x = s.mem[...].prop; x = val` will NOT work, you must say `s.mem[...].prop = val`.

For example:

```
>>> s.mem[0x601048].long
<long (64 bits) <BV64 0x4008d0> at 0x601048>
>>> s.mem[0x601048].long.resolved
<BV64 0x4008d0>
>>> s.mem[0x601048].deref
<<untyped> <unresolvable> at 0x4008d0>
>>> s.mem[0x601048].deref.string.concrete
'SOSNEAKY'
```

**__init__**(*ty=None*, *addr=None*, *state=None*)

types: ClassVar[dict] = {'CharT': char, 'DIR': struct DIR, 'FILE': struct FILE, 'FILE_t': struct FILE_t, '_Bool': bool, '_ENTRY': struct _ENTRY, '_Float128': __float128, '_IO_codecvt': struct _IO_codecvt, '_IO_iconv_t': struct _IO_iconv_t, '_IO_lock_t': struct pthread_mutex_t, '_IO_marker': struct _IO_marker, '_IO_wide_data': struct _IO_wide_data, '__action_fn_t': __action_fn_t, '__clock_t': uint32_t, '__dev_t': uint64_t, '__float128': __float128, '__free_fn_t': __free_fn_t, '__ftw_func_t': __ftw_func_t, '__gid_t': unsigned int, '__ino64_t': unsigned long long, '__ino_t': unsigned long, '__int128': int128_t, '__int256': int256_t, '__int32': int, '__int64': long long, '__m128': __m128, '__m128d': __m128d, '__m128i': __m128i, '__mbstate_t': struct __mbstate_t, '__mode_t': unsigned int, '__nlink_t': unsigned int, '__off64_t': long long, '__off_t': long, '__pid_t': int, '__suseconds_t': int64_t, '__time_t': long, '__uid_t': unsigned int, '_obstack_chunk': struct _obstack_chunk, 'aiocb': struct aiocb, 'aiocb64': struct aiocb64, 'aioinit': struct aioinit, 'argp': struct argp, 'argp_child': struct argp_child, 'argp_option': struct argp_option, 'argp_parser_t': (int, char *, struct argp_state*) -> int, 'argp_state': struct argp_state, 'basic_string': string_t, 'bool': bool, 'byte': uint8_t, 'cc_t': char, 'char': char, 'clock_t': uint32_t, 'comparison_fn_t': comparison_fn_t, 'crypt_data': struct crypt_data, 'dev_t': int, 'dirent': struct dirent, 'dirent64': struct dirent64, 'double': double, 'drand48_data': struct <anon>, 'dword': uint32_t, 'error_t': int, 'exit_status': struct exit_status, 'fd_set': struct fd_set, 'float': float, 'fpos64_t': struct fpos64_t, 'fpos_t': struct fpos_t, 'fstab': struct fstab, 'glob64_t': struct glob64_t, 'glob_t': struct glob_t, 'group': struct group, 'hostent': struct hostent, 'hsearch_data': struct hsearch_data, 'if_nameindex': struct if_nameindex, 'in_addr': struct in_addr, 'in_port_t': uint16_t, 'ino64_t': unsigned long long, 'ino_t': unsigned long, 'int': int, 'int16_t': int16_t, 'int32_t': int32_t, 'int64_t': int64_t, 'int8_t': int8_t, 'iovec': struct <anon>, 'itimerval': struct itimerval, 'lconv': struct lconv, 'long': long, 'long double': long double, 'long int': long, 'long long': long long, 'long long int': long long, 'long signed': long, 'long unsigned int': unsigned long, 'mallinfo': struct mallinfo, 'mallinfo2': struct mallinfo2, 'mbstate_t': struct mbstate_t, 'mntent': struct mntent, 'mode_t': unsigned int, 'netent': struct netent, 'ntptimeval': struct ntptimeval, 'obstack': struct obstack, 'off64_t': long long, 'off_t': long, 'option': struct option, 'passwd': struct passwd, 'pid_t': int, 'printf_info': struct printf_info, 'protoent': struct protoent, 'ptrdiff_t': long, 'qword': uint64_t, 'random_data': struct <anon>, 'regex_t': struct regex_t, 'rlim64_t': uint64_t, 'rlim_t': unsigned long, 'rlimit': struct rlimit, 'rlimit64': struct rlimit64, 'rusage': struct rusage, 'sa_family_t': unsigned short, 'sched_param': struct sched_param, 'sem_t': int, 'sembuf': struct sembuf, 'servent': struct servent, 'sgttyb': struct sgttyb, 'short': short, 'short int': short, 'sigevent': struct sigevent, 'sighandler_t': sighandler_t, 'signed': int, 'signed char': char, 'signed int': int, 'signed long': long, 'signed long int': long, 'signed long long': long long, 'signed long long int': long long, 'signed short': short, 'signed short int': short, 'sigset_t': int, 'sigstack': struct sigstack, 'sigval': union sigval { sival_int int; sival_ptr void *; }, 'size_t': size_t, 'sockaddr': struct sockaddr, 'sockaddr_in': struct sockaddr_in, 'socklen_t': uint32_t, 'speed_t': long, 'ssize': size_t, 'ssize_t': size_t, 'std::__cxx11::basic_string<char, std::char_traits<char>, std::allocator<char>>': string_t, 'string': string_t, 'struct iovec': struct <anon>, 'struct stat': struct stat, 'struct stat64': struct stat64, 'struct timespec': struct timespec, 'struct timeval': struct timeval, 'tcflag_t': unsigned long, 'termios': struct termios, 'time_t': long, 'timespec': struct timeval, 'timeval': struct timeval, 'timex': struct timex, 'timezone': struct timezone, 'tm': struct tm, 'tms': struct tms, 'uint16_t': uint16_t, 'uint32_t': uint32_t, 'uint64_t': uint64_t, 'uint8_t': uint8_t, 'uintptr_t': unsigned long, 'unsigned': unsigned int, 'unsigned __int128': uint128_t, 'unsigned __int256': uint256_t, 'unsigned char': char, 'unsigned int': unsigned int, 'unsigned long': unsigned long, 'unsigned long int': unsigned long, 'unsigned long long': unsigned long long, 'unsigned long long int': unsigned long long, 'unsigned short': unsigned short, 'unsigned short int': unsigned short,

**state:** *SimState*[Any, Any] = None

**struct:** *StructMode*

**with_type**(*sim_type*)

Returns a copy of the SimMemView with a type.

**Parameters**
**sim_type** (*SimType*) – The new type.

**Return type**
*SimMemView*

**Returns**
The typed SimMemView copy.

**property resolvable**

**property resolved**

**property concrete**

**property deref:** *SimMemView*

**array**(*n*)

**Return type**
*SimMemView*

**member**(*member_name*)

If self is a struct and member_name is a member of the struct, return that member element. Otherwise raise an exception.

**Return type**
*SimMemView*

**Parameters**
**member_name** (*str*)

**store**(*value*)

**class** angr.state_plugins.**SimMount**

Bases: *SimStatePlugin*

This is the base class for "mount points" in angr's simulated filesystem. Subclass this class and give it to the filesystem to intercept all file creations and opens below the mountpoint. Since this a SimStatePlugin you may also want to implement set_state, copy, merge, etc.

**get**(*path_elements*)

Implement this function to instrument file lookups.

**Parameters**
**path_elements** – A list of path elements traversing from the mountpoint to the file

**Returns**
A SimFile, or None

**insert**(*path_elements*, *simfile*)

Implement this function to instrument file creation.

**Parameters**

- **path_elements** – A list of path elements traversing from the mountpoint to the file
- **simfile** – The file to insert

**Returns**

A bool indicating whether the insert occurred

**delete**(*path_elements*)

Implement this function to instrument file deletion.

**Parameters**

**path_elements** – A list of path elements traversing from the mountpoint to the file

**Returns**

A bool indicating whether the delete occurred

**lookup**(*sim_file*)

Look up the path of a SimFile in the mountpoint

**Parameters**

**sim_file** – A SimFile object needs to be looked up

**Returns**

A string representing the path of the file in the mountpoint Or None if the SimFile does not exist in the mountpoint

**class** angr.state_plugins.**SimRegNameView**

Bases: *SimStatePlugin*

**get**(*reg_name*)

**class** angr.state_plugins.**SimSolver**

Bases: *SimStatePlugin*

This is the plugin you'll use to interact with symbolic variables, creating them and evaluating them. It should be available on a state as `state.solver`.

Any top-level variable of the claripy module can be accessed as a property of this object.

**__init__**(*solver=None*, *all_variables=None*, *temporal_tracked_variables=None*, *eternal_tracked_variables=None*)

**reload_solver**(*constraints=None*)

Reloads the solver. Useful when changing solver options.

**Parameters**

**constraints** (*list*) – A new list of constraints to use in the reloaded solver instead of the current one

**get_variables**(**keys*)

Iterate over all variables for which their tracking key is a prefix of the values provided.

Elements are a tuple, the first element is the full tracking key, the second is the symbol.

```
>>> list(s.solver.get_variables('mem'))
[(('mem', 0x1000), <BV64 mem_1000_4_64>), (('mem', 0x1008), <BV64 mem_1008_5_64>
↪)]
```

```
>>> list(s.solver.get_variables('file'))
[(('file', 1, 0), <BV8 file_1_0_6_8>), (('file', 1, 1), <BV8 file_1_1_7_8>),
    (('file', 2, 0), <BV8 file_2_0_8_8>)]
```

```
>>> list(s.solver.get_variables('file', 2))
[(('file', 2, 0), <BV8 file_2_0_8_8>)]
```

```
>>> list(s.solver.get_variables())
[(('mem', 0x1000), <BV64 mem_1000_4_64>), (('mem', 0x1008), <BV64 mem_1008_5_64>
↪),
    (('file', 1, 0), <BV8 file_1_0_6_8>), (('file', 1, 1), <BV8 file_1_1_7_8>),
    (('file', 2, 0), <BV8 file_2_0_8_8>)]
```

**register_variable**(*v*, *key*, *eternal=True*)

Register a value with the variable tracking system

**Parameters**

- **v** – The BVS to register
- **key** – A tuple to register the variable under

**Parma eternal**
Whether this is an eternal variable, default True. If False, an incrementing counter will be appended to the key.

**describe_variables**(*v*)

Given an AST, iterate over all the keys of all the BVS leaves in the tree which are registered.

**Unconstrained**(*name*, *bits*, *uninitialized=True*, *inspect=True*, *events=True*, *key=None*, *eternal=False*, *uc_alloc_depth=None*, ***kwargs*)

Creates an unconstrained symbol or a default concrete value (0), based on the state options.

**Parameters**

- **name** – The name of the symbol.
- **bits** – The size (in bits) of the symbol.
- **uninitialized** – Whether this value should be counted as an "uninitialized" value in the course of an analysis.
- **inspect** – Set to False to avoid firing SimInspect breakpoints
- **events** – Set to False to avoid generating a SimEvent for the occasion
- **key** – Set this to a tuple of increasingly specific identifiers (for example, `('mem', 0xffbeff00)` or `('file', 4, 0x20)` to cause it to be tracked, i.e. accessible through `solver.get_variables`.
- **eternal** – Set to True in conjunction with setting a key to cause all states with the same ancestry to retrieve the same symbol when trying to create the value. If False, a counter will be appended to the key.

**Returns**
an unconstrained symbol (or a concrete value of 0).

**BVS**(*name*, *size*, *min=None*, *max=None*, *stride=None*, *uninitialized=False*, *explicit_name=False*, *key=None*, *eternal=False*, *inspect=True*, *events=True*, ***kwargs*)

Creates a bit-vector symbol (i.e., a variable). Other keyword parameters are passed directly on to the constructor of claripy.ast.BV.

**Parameters**

- **name** – The name of the symbol.
- **size** – The size (in bits) of the bit-vector.
- **min** – The minimum value of the symbol. Note that this **only** work when using VSA.
- **max** – The maximum value of the symbol. Note that this **only** work when using VSA.
- **stride** – The stride of the symbol. Note that this **only** work when using VSA.
- **uninitialized** – Whether this value should be counted as an "uninitialized" value in the course of an analysis.
- **explicit_name** – Set to True to prevent an identifier from appended to the name to ensure uniqueness.
- **key** – Set this to a tuple of increasingly specific identifiers (for example, `('mem', 0xffbeff00)` or `('file', 4, 0x20)` to cause it to be tracked, i.e. accessible through `solver.get_variables`.
- **eternal** – Set to True in conjunction with setting a key to cause all states with the same ancestry to retrieve the same symbol when trying to create the value. If False, a counter will be appended to the key.
- **inspect** – Set to False to avoid firing SimInspect breakpoints
- **events** – Set to False to avoid generating a SimEvent for the occasion

**Returns**
A BV object representing this symbol.

`downsize()`

Frees memory associated with the constraint solver by clearing all of its internal caches.

`property constraints`

Returns the constraints of the state stored by the solver.

`eval_to_ast(`*e*, *n*, *extra_constraints=()*, *exact=None*`)`

Evaluate an expression, using the solver if necessary. Returns AST objects.

**Parameters**

- **e** – the expression
- **n** – the number of desired solutions
- **extra_constraints** – extra constraints to apply to the solver
- **exact** – if False, returns approximate solutions

**Returns**
a tuple of the solutions, in the form of claripy AST nodes

**Return type**
tuple

**max**(*e*, *extra_constraints=()*, *exact=None*, *signed=False*)

Return the maximum value of expression *e*.

:param e : expression (an AST) to evaluate :type extra_constraints: :param extra_constraints: extra constraints (as ASTs) to add to the solver for this solve :param exact : if False, return approximate solutions. :param signed : Whether the expression should be treated as a signed value. :return: the maximum possible value of e (backend object)

**min**(*e*, *extra_constraints=()*, *exact=None*, *signed=False*)

Return the minimum value of expression *e*.

:param e : expression (an AST) to evaluate :type extra_constraints: :param extra_constraints: extra constraints (as ASTs) to add to the solver for this solve :param exact : if False, return approximate solutions. :param signed : Whether the expression should be treated as a signed value. :return: the minimum possible value of e (backend object)

**solution**(*e*, *v*, *extra_constraints=()*, *exact=None*)

Return True if *v* is a solution of *expr* with the extra constraints, False otherwise.

**Parameters**

- **e** – An expression (an AST) to evaluate
- **v** – The proposed solution (an AST)
- **extra_constraints** – Extra constraints (as ASTs) to add to the solver for this solve.
- **exact** – If False, return approximate solutions.

**Returns**

True if *v* is a solution of *expr*, False otherwise

**is_true**(*e*, *extra_constraints=()*, *exact=None*)

If the expression provided is absolutely, definitely a true boolean, return True. Note that returning False doesn't necessarily mean that the expression can be false, just that we couldn't figure that out easily.

**Parameters**

- **e** – An expression (an AST) to evaluate
- **extra_constraints** – Extra constraints (as ASTs) to add to the solver for this solve.
- **exact** – If False, return approximate solutions.

**Returns**

True if *v* is definitely true, False otherwise

**is_false**(*e*, *extra_constraints=()*, *exact=None*)

If the expression provided is absolutely, definitely a false boolean, return True. Note that returning False doesn't necessarily mean that the expression can be true, just that we couldn't figure that out easily.

**Parameters**

- **e** – An expression (an AST) to evaluate
- **extra_constraints** – Extra constraints (as ASTs) to add to the solver for this solve.
- **exact** – If False, return approximate solutions.

**Returns**

True if *v* is definitely false, False otherwise

**unsat_core**(*extra_constraints=()*)

This function returns the unsat core from the backend solver.

**Parameters**
**extra_constraints** – Extra constraints (as ASTs) to add to the solver for this solve.

**Returns**
The unsat core.

**satisfiable**(*extra_constraints=()*, *exact=None*)

This function does a constraint check and checks if the solver is in a sat state.

**Parameters**

- **extra_constraints** – Extra constraints (as ASTs) to add to s for this solve
- **exact** – If False, return approximate solutions.

**Returns**
True if sat, otherwise false

**add**(**constraints*)

Add some constraints to the solver.

**Parameters**
**constraints** – Pass any constraints that you want to add (ASTs) as varargs.

**CastType = ~CastType**

**eval_upto**(*e*, *n*, *cast_to=None*, ***kwargs*)

Evaluate an expression, using the solver if necessary. Returns primitives as specified by the *cast_to* parameter. Only certain primitives are supported, check the implementation of *_cast_to* to see which ones.

**Overloads**

- **e** (BV), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[int]
- **e** (BV), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (Bool), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[bool]
- **e** (Bool), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (FP), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[float]
- **e** (FP), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (String | str), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[str]
- **e** (), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[Any]
- **e** (), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]

**Parameters**

- **e** – the expression
- **n** – the number of desired solutions
- **extra_constraints** – extra constraints to apply to the solver
- **exact** – if False, returns approximate solutions
- **cast_to** – desired type of resulting values

**Returns**
a tuple of the solutions, in the form of Python primitives

**Return type**
tuple

**eval**(*e*, *cast_to=None*, ***kwargs*)

Evaluate an expression to get any possible solution. The desired output types can be specified using the *cast_to* parameter. *extra_constraints* can be used to specify additional constraints the returned values must satisfy.

**Overloads**

- **e** (BV), **cast_to** (None) = ..., ****kwargs** → int
- **e** (BV), **cast_to** (type[CastType]), ****kwargs** → CastType
- **e** (Bool), **cast_to** (None) = ..., ****kwargs** → bool
- **e** (Bool), **cast_to** (type[CastType]), ****kwargs** → CastType
- **e** (FP), **cast_to** (None) = ..., ****kwargs** → float
- **e** (FP), **cast_to** (type[CastType]), ****kwargs** → CastType
- **e** (String | str), **cast_to** (None) = ..., ****kwargs** → str
- **e** (), **cast_to** (None) = ..., ****kwargs** →
- **e** (), **cast_to** (type[CastType]), ****kwargs** → CastType

**Parameters**

- **e** – the expression to get a solution for
- **kwargs** – Any additional kwargs will be passed down to *eval_upto*
- **cast_to** – desired type of resulting values

**Raises**
***SimUnsatError*** – if no solution could be found satisfying the given constraints

**Returns**

**eval_one**(*e*, *cast_to=None*, ***kwargs*)

Evaluate an expression to get the only possible solution. Errors if either no or more than one solution is returned. A kwarg parameter *default* can be specified to be returned instead of failure!

**Overloads**

- **e** (BV), **cast_to** (None) = ..., ****kwargs** → int
- **e** (BV), **cast_to** (type[CastType]), ****kwargs** → CastType
- **e** (Bool), **cast_to** (None) = ..., ****kwargs** → bool
- **e** (Bool), **cast_to** (type[CastType]), ****kwargs** → CastType
- **e** (FP), **cast_to** (None) = ..., ****kwargs** → float
- **e** (FP), **cast_to** (type[CastType]), ****kwargs** → CastType
- **e** (String | str), **cast_to** (None) = ..., ****kwargs** → str
- **e** (), **cast_to** (None) = ..., ****kwargs** →
- **e** (), **cast_to** (type[CastType]), ****kwargs** → CastType

**Parameters**

- **e** – the expression to get a solution for

- **cast_to** – desired type of resulting values
- **default** – A value can be passed as a kwarg here. It will be returned in case of failure.
- **kwargs** – Any additional kwargs will be passed down to *eval_upto*

**Raises**

- ***SimUnsatError*** – if no solution could be found satisfying the given constraints
- ***SimValueError*** – if more than one solution was found to satisfy the given constraints

**Returns**
The value for *e*

**eval_atmost**(*e*, *n*, *cast_to=None*, ***kwargs*)

Evaluate an expression to get at most *n* possible solutions. Errors if either none or more than *n* solutions are returned.

**Overloads**

- **e** (BV), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[int]
- **e** (BV), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (Bool), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[bool]
- **e** (Bool), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (FP), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[float]
- **e** (FP), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (String | str), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[str]
- **e** (), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[Any]
- **e** (), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]

**Parameters**

- **e** – the expression to get a solution for
- **n** – the inclusive upper limit on the number of solutions
- **cast_to** – desired type of resulting values
- **kwargs** – Any additional kwargs will be passed down to *eval_upto*

**Raises**

- ***SimUnsatError*** – if no solution could be found satisfying the given constraints
- ***SimValueError*** – if more than *n* solutions were found to satisfy the given constraints

**Returns**
The solutions for *e*

**eval_atleast**(*e*, *n*, *cast_to=None*, ***kwargs*)

Evaluate an expression to get at least *n* possible solutions. Errors if less than *n* solutions were found.

**Overloads**

- **e** (BV), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[int]
- **e** (BV), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (Bool), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[bool]

- **e** (Bool), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (FP), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[float]
- **e** (FP), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (String | str), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[str]
- **e** (), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[Any]
- **e** (), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]

**Parameters**

- **e** – the expression to get a solution for
- **n** – the inclusive lower limit on the number of solutions
- **cast_to** – desired type of resulting values
- **kwargs** – Any additional kwargs will be passed down to *eval_upto*

**Raises**

- ***SimUnsatError*** – if no solution could be found satisfying the given constraints
- ***SimValueError*** – if less than *n* solutions were found to satisfy the given constraints

**Returns**

The solutions for *e*

**eval_exact**(*e*, *n*, *cast_to=None*, ***kwargs*)

Evaluate an expression to get exactly the *n* possible solutions. Errors if any number of solutions other than *n* was found to exist.

**Overloads**

- **e** (BV), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[int]
- **e** (BV), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (Bool), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[bool]
- **e** (Bool), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (FP), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[float]
- **e** (FP), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (String | str), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[str]
- **e** (), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[Any]
- **e** (), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]

**Parameters**

- **e** – the expression to get a solution for
- **n** – the inclusive lower limit on the number of solutions
- **cast_to** – desired type of resulting values
- **kwargs** – Any additional kwargs will be passed down to *eval_upto*

**Raises**

- ***SimUnsatError*** – if no solution could be found satisfying the given constraints

- *SimValueError* – if any number of solutions other than *n* were found to satisfy the given constraints

**Returns**
The solutions for *e*

**min_int**(*e*, *extra_constraints=()*, *exact=None*, *signed=False*)

Return the minimum value of expression *e*.

:param e : expression (an AST) to evaluate :type extra_constraints: :param extra_constraints: extra constraints (as ASTs) to add to the solver for this solve :param exact : if False, return approximate solutions. :param signed : Whether the expression should be treated as a signed value. :return: the minimum possible value of e (backend object)

**max_int**(*e*, *extra_constraints=()*, *exact=None*, *signed=False*)

Return the maximum value of expression *e*.

:param e : expression (an AST) to evaluate :type extra_constraints: :param extra_constraints: extra constraints (as ASTs) to add to the solver for this solve :param exact : if False, return approximate solutions. :param signed : Whether the expression should be treated as a signed value. :return: the maximum possible value of e (backend object)

**unique**(*e*, ***kwargs*)

Returns True if the expression *e* has only one solution by querying the constraint solver. It does also add that unique solution to the solver's constraints.

**symbolic**(*e*)

Returns True if the expression *e* is symbolic.

**single_valued**(*e*)

Returns True whether *e* is a concrete value or is a value set with only 1 possible value. This differs from *unique* in that this *does* not query the constraint solver.

**simplify**(*e=None*)

Simplifies *e*. If *e* is None, simplifies the constraints of this state.

**variables**(*e*)

Returns the symbolic variables present in the AST of *e*.

**class** angr.state_plugins.**SimStateCGC**

Bases: *SimStatePlugin*

This state plugin keeps track of CGC state.

**EBADF = 1**

**EFAULT = 2**

**EINVAL = 3**

**ENOMEM = 4**

**ENOSYS = 5**

**EPIPE = 6**

**FD_SETSIZE = 1024**

**max_allocation = 268435456**

**__init__**()

**peek_input**()

**discard_input**(*num_bytes*)

**peek_output**()

**discard_output**(*num_bytes*)

**addr_invalid**(*a*)

**get_max_sinkhole**(*length*)

Find a sinkhole which is large enough to support *length* bytes.

This uses first-fit. The first sinkhole (ordered in descending order by their address) which can hold *length* bytes is chosen. If there are more than *length* bytes in the sinkhole, a new sinkhole is created representing the remaining bytes while the old sinkhole is removed.

**add_sinkhole**(*address*, *length*)

Add a sinkhole.

Allow the possibility for the program to reuse the memory represented by the address length pair.

**class** angr.state_plugins.**SimStateEdgeHitmap**

Bases: *SimStatePlugin*

A state plugin that stores AFL-style edge hitmap coverage data.

This plugin is used by the Icicle engine to track edge coverage during concrete execution. It stores the hitmap as raw bytes, which can be efficiently passed to and from the Icicle emulator.

This plugin is NOT registered as a default plugin - it must be explicitly added to states that need edge coverage tracking.

**HITMAP_SIZE = 65536**

**__init__**(*edge_hitmap=None*)

Initialize the edge hitmap plugin.

**Parameters**

**edge_hitmap** (bytes | None) – Initial edge hitmap bytes, or None to start with a zeroed hitmap.

**copy**(*memo*)

Create a copy of the plugin.

**Parameters**

**memo** – Memoization dictionary to avoid duplicate copies.

**Returns**

A new SimStateEdgeHitmap instance with a copy of the hitmap.

**merge**(*others*, *merge_conditions*, *common_ancestor=None*)

Merge multiple hitmap plugins.

For coverage tracking, we OR the hitmaps together to preserve all observed edges.

**Parameters**

- **others** – Other plugin instances to merge with.
- **merge_conditions** – Symbolic conditions for each merge branch.

- **common_ancestor** – Common ancestor plugin instance.

**Returns**
True if merge was successful.

class angr.state_plugins.**SimStateGlobals**

Bases: *SimStatePlugin*

**__init__**(*backer=None*)

**keys**()

**values**()

**items**()

**get**(*k*, *alt=None*)

**pop**(*k*, *alt=None*)

class angr.state_plugins.**SimStateHistory**

Bases: *SimStatePlugin*

This class keeps track of historically-relevant information for paths.

**__init__**(*parent=None*, *clone=None*)

**property addr**

**trim**()

Discard the ancestry of this state.

**filter_actions**(*start_block_addr=None*, *end_block_addr=None*, *block_stmt=None*, *insn_addr=None*, *read_from=None*, *write_to=None*)

Filter self.actions based on some common parameters.

[start_block_addr, end_block_addr]

**Parameters**

- **start_block_addr** – Only return actions generated in blocks starting at this address.
- **end_block_addr** – Only return actions generated in blocks ending at this address.
- **block_stmt** – Only return actions generated in the nth statement of each block.
- **insn_addr** – Only return actions generated in the assembly instruction at this address.
- **read_from** – Only return actions that perform a read from the specified location.
- **write_to** – Only return actions that perform a write to the specified location.

Notes: If IR optimization is turned on, reads and writes may not occur in the instruction they originally came from. Most commonly, If a register is read from twice in the same block, the second read will not happen, instead reusing the temp the value is already stored in.

Valid values for read_from and write_to are the string literals 'reg' or 'mem' (matching any read or write to registers or memory, respectively), any string (representing a read or write to the named register), and any integer (representing a read or write to the memory at this address).

**demote**()

Demotes this history node, causing it to drop the strong state reference.

reachable()

add_event(*event_type*, ***kwargs*)

add_action(*action*)

extend_actions(*new_actions*)

subscribe_actions()

property recent_constraints

property recent_actions

property block_count

property lineage

property parents

property events: Reversible[*SimEvent*]

property actions: Reversible[*SimAction*]

property jumpkinds: Reversible[str]

property jump_guards: Reversible[Bool]

property jump_targets

property jump_sources

property descriptions: Reversible[str]

property bbl_addrs: Reversible[int]

property ins_addrs: Reversible[int]

property stack_actions

property last_edge_hitmap: bytes | None

Returns the last edge hitmap in the history chain, or None if there is no edge hitmap.

closest_common_ancestor(*other*)

Find the common ancestor between this history node and 'other'.

**Parameters**
**other** – the PathHistory to find a common ancestor with.

**Returns**
the common ancestor SimStateHistory, or None if there isn't one

constraints_since(*other*)

Returns the constraints that have been accumulated since *other*.

**Parameters**
**other** – a prior PathHistory object

**Returns**
a list of constraints

make_child()

class angr.state_plugins.SimStateIcicle

Bases: SimStatePlugin

Engine-internal plugin for IcicleEngine continuation detection.

Attached to states produced by IcicleEngine.process(). Owns the VM and the metadata the engine needs to decide whether the next call is a lightweight continuation or requires a full snapshot restore.

__init__(*vm_ref=None*, *generation=None*, *base_translation_data=None*, *translation_data=None*, *dirty_pages=None*)

**Parameters**

- **vm_ref** (IcicleVMRef | *None*)
- **generation** (*int* | *None*)
- **base_translation_data** (IcicleStateTranslationData | *None*)
- **translation_data** (IcicleStateTranslationData | *None*)
- **dirty_pages** (*set[int]* | *None*)

property is_live: bool

True when the VM is still positioned where this state last left it.

class angr.state_plugins.SimStateJNIReferences

Bases: SimStatePlugin

Management of the mapping between opaque JNI references and the corresponding Java objects.

__init__(*local_refs=None*, *global_refs=None*)

lookup(*opaque_ref*)

Lookups the object that was used for creating the reference.

create_new_reference(*obj*, *global_ref=False*)

Create a new reference thats maps to the given object.

**Parameters**

- **obj** – Object which gets referenced.
- **global_ref** (*bool*) – Whether a local or global reference is created.

clear_local_references()

Clear all local references.

delete_reference(*opaque_ref*, *global_ref=False*)

Delete the stored mapping of a reference.

**Parameters**

- **opaque_ref** – Reference which should be removed.
- **global_ref** (*bool*) – Whether opaque_ref is a local or global reference.

class angr.state_plugins.SimStateLibc

Bases: SimStatePlugin

This state plugin keeps track of various libc stuff:

```
LOCALE_ARRAY = [b'\x00\x00', b'\x00\x00', b'\x00\x00', b'\x00\x00', b'\x00\x00',
b'\x00\x00',
```

TOLOWER_LOC_ARRAY = [128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139,

__init__()

property errno

ret_errno(*val*)

class angr.state_plugins.**SimStateLog**

Bases: *SimStatePlugin*

**__init__**(*log=None*)

**property actions**

**add_event**(*event_type*, ***kwargs*)

**add_action**(*action*)

**extend_actions**(*new_actions*)

**events_of_type**(*event_type*)

**actions_of_type**(*action_type*)

**property fresh_constraints**

**clear**()

class angr.state_plugins.**SimStateLoopData**

Bases: *SimStatePlugin*

This class keeps track of loop-related information for states. Note that we have 2 counters for loop iterations (trip counts): the first recording the number of times one of the back edges (or continue edges) of a loop is taken, whereas the second recording the number of times the loop header (or loop entry) is executed. These 2 counters may differ since compilers usually optimize loops hence completely change the loop structure at the binary level. This is supposed to be used with *LoopSeer* exploration technique, which monitors loop execution. For the moment, the only thing we want to analyze is loop trip counts, but nothing prevents us from extending this plugin for other loop analyses.

**__init__**(*back_edge_trip_counts=None*, *header_trip_counts=None*, *current_loop=None*)

**Parameters**

- **back_edge_trip_counts** – Dictionary that stores back edge based trip counts for each loop. Keys are address of loop headers.
- **header_trip_counts** – Dictionary that stores header based trip counts for each loop. Keys are address of loop headers.
- **current_loop** – List of currently running loops. Each element is a tuple (loop object, list of loop exits).

class angr.state_plugins.**SimStatePlugin**

Bases: object

This is a base class for SimState plugins. A SimState plugin will be copied along with the state when the state is branched. They are intended to be used for things such as tracking open files, tracking heap details, and providing storage and persistence for SimProcedures.

**__init__**()

**Return type**
None

**state:** *SimState*[Any, Any]

**set_state**(*state*)

Sets a new state (for example, if the state has been branched)

**Return type**
None

**static memo**[*S_co*](*f*)

A decorator function you should apply to copy

**Return type**
_CopyFunc[S_co]

**Parameters**
**f** (*Callable[[Any, dict[int, Any]], S_co]*)

**copy**(*_memo*)

Should return a copy of the plugin without any state attached. Should check the memo first, and add itself to memo if it ends up making a new copy.

In order to simplify using the memo, you should annotate implementations of this function with SimStatePlugin.memo

The base implementation of this function constructs a new instance of the plugin's class without calling its initializer. If you super-call down to it, make sure you instantiate all the fields in your copy method!

**Parameters**

- **memo** – A dictionary mapping object identifiers (id(obj)) to their copied instance. Use this to avoid infinite recursion and diverged copies.
- **_memo** (*dict[int, Any]*)

**Return type**
*SimStatePlugin*

**merge**(*others*, *merge_conditions*, *common_ancestor=None*)

Should merge the state plugin with the provided others. This will be called by state.merge() after copying the target state, so this should mutate the current instance to merge with the others.

Note that when multiple instances of a single plugin object (for example, a file) are referenced in the state, it is important that merge only ever be called once. This should be solved by designating one of the plugin's referees as the "real owner", who should be the one to actually merge it. This technique doesn't work to resolve the similar issue that arises during copying because merging doesn't produce a new reference to insert.

There will be n others and n+1 merge conditions, since the first condition corresponds to self. To match elements up to conditions, say zip([self] + others, merge_conditions)

When implementing this, make sure that you "deepen" both others and common_ancestor before calling sub-elements' merge methods, e.g.

```
self.foo.merge(
    [o.foo for o in others],
    merge_conditions,
    common_ancestor=common_ancestor.foo if common_ancestor is not None else None
)
```

During static analysis, merge_conditions can be None, in which case you should use state.solver.union(values). TODO: fish please make this less bullshit

There is a utility `claripy.ite_cases` which will help with constructing arbitrarily large merged ASTs. Use it like `self.bar = claripy.ite_cases(zip(conditions[1:], [o.bar for o in others]), self.bar)`

**Parameters**

- **others** – the other state plugins to merge with
- **merge_conditions** – a symbolic condition for each of the plugins
- **common_ancestor** – a common ancestor of this plugin and the others being merged

**Returns**
True if the state plugins are actually merged.

**Return type**
bool

**classmethod register_default**(*name*, *xtr=None*)

**Return type**
None

**Parameters**

- **name** (*str*)
- **xtr** (type[SimStatePlugin] | *str* | *None*)

**init_state**()

Use this function to perform any initialization on the state at plugin-add time

**Return type**
None

**class** angr.state_plugins.**SimStatePreconstrainer**

Bases: *SimStatePlugin*

This state plugin manages the concept of preconstraining - adding constraints which you would like to remove later.

**Parameters**
**constrained_addrs** – SimActions for memory operations whose addresses should be constrained during crash analysis

**__init__**(*constrained_addrs=None*)

**preconstrain**(*value*, *variable*)

Add a preconstraint that `variable == value` to the state.

**Parameters**

- **value** – The concrete value. Can be a bitvector or a bytestring or an integer.
- **variable** – The BVS to preconstrain.

**preconstrain_file**(*content*, *simfile*, *set_length=False*)

Preconstrain the contents of a file.

**Parameters**

- **content** – The content to preconstrain the file to. Can be a bytestring or a list thereof.
- **simfile** – The actual simfile to preconstrain

**preconstrain_flag_page**(*magic_content*)

Preconstrain the data in the flag page.

**Parameters**
**magic_content** – The content of the magic page as a bytestring.

**remove_preconstraints**(*to_composite_solver=True*, *simplify=True*)

Remove the preconstraints from the state.

If you are using the zen plugin, this will also use that to filter the constraints.

**Parameters**

- **to_composite_solver** – Whether to convert the replacement solver to a composite solver. You probably want this if you're switching from tracing to symbolic analysis.
- **simplify** – Whether to simplify the resulting set of constraints.

**reconstrain**()

Split the solver. If any of the subsolvers time out after a short timeout (10 seconds), re-add the preconstraints associated with each of its variables. Hopefully these constraints still allow us to do meaningful things to the state.

**class** angr.state_plugins.**SimStateScratch**

Bases: *SimStatePlugin*

Implements the scratch state plugin.

**__init__**(*scratch=None*)

**property ail_block_idx**

**property is_ail**

**property priv**

**push_priv**(*priv*)

**pop_priv**()

**set_tyenv**(*tyenv*)

**tmp_expr**(*tmp*)

Returns the Claripy expression of a VEX temp value.

**Parameters**

- **tmp** – the number of the tmp
- **simplify** – simplify the tmp before returning it

**Returns**
a Claripy expression of the tmp

**store_tmp**(*tmp*, *content*, *reg_deps=frozenset({})*, *tmp_deps=frozenset({})*, *deps=None*, ***kwargs*)

Stores a Claripy expression in a VEX temp value. If in symbolic mode, this involves adding a constraint for the tmp's symbolic variable.

**Parameters**

- **tmp** – the number of the tmp
- **content** – a Claripy expression of the content

- **reg_deps** – the register dependencies of the content
- **tmp_deps** – the temporary value dependencies of the content

**clear**()

**class** angr.state_plugins.**SimSymbolizer**

Bases: *SimStatePlugin*

The symbolizer state plugin ensures that pointers that are stored in memory are symbolic. This allows for the tracking of and reasoning over these pointers (for example, to reason about memory disclosure).

**__init__**()

**set_symbolization_for_all_pages**()

Sets the symbolizer to symbolize pointers to all pages as they are written to memory..

**set_symbolized_target_range**(*base*, *length*)

All pointers to the target range will be symbolized as they are written to memory.

Due to optimizations, the _pages_ containing this range will be set as symbolization targets, not just the range itself.

**resymbolize**()

Re-symbolizes all pointers in memory. This can be called to symbolize any pointers to target regions that were written (and not mangled beyond recognition) before symbolization was set.

**class** angr.state_plugins.**SimSystemPosix**

Bases: *SimStatePlugin*

Data storage and interaction mechanisms for states with an environment conforming to posix. Available as `state.posix`.

**SIG_BLOCK = 0**

**SIG_UNBLOCK = 1**

**SIG_SETMASK = 2**

**EPERM = 1**

**ENOMEM = 12**

**EACCES = 13**

**EFAULT = 14**

**ENOTBLK = 15**

**EBUSY = 16**

**EEXIST = 17**

**EXDEV = 18**

**ENODEV = 19**

**ENOTDIR = 20**

**EISDIR = 21**

**EINVAL = 22**

**ENFILE = 23**

**EMFILE = 24**

**ENOTTY = 25**

**ETXTBSY = 26**

**EFBIG = 27**

**ENOSPC = 28**

**ESPIPE = 29**

**EROFS = 30**

**EMLINK = 31**

**EPIPE = 32**

**EDOM = 33**

**ERANGE = 34**

**__init__**(*stdin=None*, *stdout=None*, *stderr=None*, *fd=None*, *sockets=None*, *socket_queue=None*, *argv=None*, *argc=None*, *environ=None*, *auxv=None*, *tls_modules=None*, *sigmask=None*, *pid=None*, *ppid=None*, *uid=None*, *gid=None*, *brk=None*)

**property closed_fds**

**set_brk**(*new_brk*)

**open**(*name*, *flags*, *preferred_fd=None*)

Open a symbolic file. Basically open(2).

**Parameters**

- **name** (`string or bytes`) – Path of the symbolic file, as a string or bytes.
- **flags** – File operation flags, a bitfield of constants from open(2), as an AST

- **preferred_fd** – Assign this fd if it's not already claimed.

**Returns**
The file descriptor number allocated (maps through posix.get_fd to a SimFileDescriptor) or -1 if the open fails.

mode from open(2) is unsupported at present.

**open_socket**(*ident*)

**get_fd**(*fd*, *create_file=True*)

Looks up the SimFileDescriptor associated with the given number (an AST). If the number is concrete and does not map to anything, return None. If the number is symbolic, constrain it to an open fd and create a new file for it. Set create_file to False if no write-access is planned (i.e. fd is read-only).

**get_concrete_fd**(*fd*, *create_file=True*)

Same behavior as get_fd(fd), only the result is a concrete integer fd (or -1) instead of a SimFileDescriptor.

**close**(*fd*)

Closes the given file descriptor (an AST). Returns whether the operation succeeded (a concrete boolean)

**fstat**(*fd*)

**fstat_with_result**(*sim_fd*)

**sigmask**(*sigsetsize=None*)

Gets the current sigmask. If it's blank, a new one is created (of sigsetsize).

**Parameters**
**sigsetsize** – the size (in *bytes* of the sigmask set)

**Returns**
the sigmask

**sigprocmask**(*how*, *new_mask*, *sigsetsize*, *valid_ptr=True*)

Updates the signal mask.

**Parameters**

- **how** – the "how" argument of sigprocmask (see manpage)
- **new_mask** – the mask modification to apply
- **sigsetsize** – the size (in *bytes* of the sigmask set)
- **valid_ptr** – is set if the new_mask was not NULL

**dump_file_by_path**(*path*, ***kwargs*)

Returns the concrete content for a file by path.

**Parameters**

- **path** – file path as string
- **kwargs** – passed to state.solver.eval

**Returns**
file contents as string

**dumps**(*fd*, ***kwargs*)

Returns the concrete content for a file descriptor.

BACKWARD COMPATIBILITY: if you ask for file descriptors 0 1 or 2, it will return the data from stdin, stdout, or stderr as a flat string.

**Parameters**
**fd** – A file descriptor.

**Returns**
The concrete content.

**Return type**
str

class angr.state_plugins.**SimUCManager**

Bases: *SimStatePlugin*

**__init__**(*man=None*)

**assign**(*dst_addr_ast*)

Assign a new region for under-constrained symbolic execution.

**Parameters**
**dst_addr_ast** – the symbolic AST which address of the new allocated region will be assigned to.

**Returns**
as ast of memory address that points to a new region

**get_alloc_depth**(*addr*)

**Return type**
int | None

**Parameters**
**addr** (*int | Base*)

**set_alloc_depth**(*addr*, *depth*)

**Parameters**

- **addr** (*Base*)
- **depth** (*int*)

**is_bounded**(*ast*)

Test whether an AST is bounded by any existing constraint in the related solver.

**Parameters**
**ast** – an claripy.AST object

**Returns**
True if there is at least one related constraint, False otherwise

class angr.state_plugins.**Stat**

Bases: tuple

Stat(st_dev, st_ino, st_nlink, st_mode, st_uid, st_gid, st_rdev, st_size, st_blksize, st_blocks, st_atime, st_atimensec, st_mtime, st_mtimensec, st_ctime, st_ctimensec)

**static __new__**(*_cls*, *st_dev*, *st_ino*, *st_nlink*, *st_mode*, *st_uid*, *st_gid*, *st_rdev*, *st_size*, *st_blksize*, *st_blocks*, *st_atime*, *st_atimensec*, *st_mtime*, *st_mtimensec*, *st_ctime*, *st_ctimensec*)

Create new instance of Stat(st_dev, st_ino, st_nlink, st_mode, st_uid, st_gid, st_rdev, st_size, st_blksize, st_blocks, st_atime, st_atimensec, st_mtime, st_mtimensec, st_ctime, st_ctimensec)

**st_atime**

Alias for field number 10

**st_atimensec**
Alias for field number 11

**st_blksize**
Alias for field number 8

**st_blocks**
Alias for field number 9

**st_ctime**
Alias for field number 14

**st_ctimensec**
Alias for field number 15

**st_dev**
Alias for field number 0

**st_gid**
Alias for field number 5

**st_ino**
Alias for field number 1

**st_mode**
Alias for field number 3

**st_mtime**
Alias for field number 12

**st_mtimensec**
Alias for field number 13

**st_nlink**
Alias for field number 2

**st_rdev**
Alias for field number 6

**st_size**
Alias for field number 7

**st_uid**
Alias for field number 4

**class** angr.state_plugins.**StructMode**
Bases: object

**__init__**(*view*)

**class** angr.state_plugins.**Unicorn**
Bases: *SimStatePlugin*

setup the unicorn engine for a state

**UC_CONFIG = {}**

**__init__**(*syscall_hooks=None*, *cache_key=None*, *unicount=None*, *symbolic_var_counts=None*, *symbolic_inst_counts=None*, *concretized_asts=None*, *always_concretize=None*, *never_concretize=None*, *concretize_at=None*, *concretization_threshold_memory=None*, *concretization_threshold_registers=None*, *concretization_threshold_instruction=None*, *cooldown_symbolic_stop=2*, *cooldown_unsupported_stop=2*, *cooldown_nonunicorn_blocks=100*, *cooldown_stop_point=1*, *max_steps=1000000*)

Initializes the Unicorn plugin for angr. This plugin handles communication with UnicornEngine.

**property uc**

**static delete_uc**()

**set_last_block_details**(*details*)

**set_stops**(*stop_points*)

**set_tracking**(*track_bbls*, *track_stack*)

**hook**()

**uncache_region**(*addr*, *length*)

## 10.45.1 angr.state_plugins.callstack

**class** angr.state_plugins.callstack.**CallStack**

Bases: *SimStatePlugin*

Stores the address of the function you're in and the value of SP at the VERY BOTTOM of the stack, i.e. points to the return address.

**__init__**(*call_site_addr=0*, *func_addr=0*, *stack_ptr=0*, *ret_addr=0*, *jumpkind='Ijk_Call'*, *next_frame=None*, *invoke_return_variable=None*)

**Parameters**
**next_frame** (*Self | None*)

**copy_without_tail**(*memo*)

**property current_function_address**

Address of the current function.

**Returns**
the address of the function

**Return type**
int

**property current_stack_pointer**

Get the value of the stack pointer.

**Returns**
Value of the stack pointer

**Return type**
int

**property current_return_target**

Get the return target.

**Returns**
The address of return target.

**Return type**
int

**static stack_suffix_to_string**(*stack_suffix*)

Convert a stack suffix to a human-readable string representation. :type stack_suffix: tuple :param stack_suffix: The stack suffix. :return: A string representation :rtype: str

**property top: Self**

Returns the element at the top of the callstack without removing it.

**Returns**
A CallStack.

**push**(*cf*)

Push the frame cf onto the stack. Return the new stack.

**Return type**
Self

**Parameters**
**cf** (*Self*)

**pop**()

Pop the top frame from the stack. Return the new stack.

**call**(*callsite_addr*, *addr*, *retn_target=None*, *stack_pointer=None*)

Push a stack frame into the call stack. This method is called when calling a function in CFG recovery.

**Parameters**

- **callsite_addr** (*int*) – Address of the call site
- **addr** (*int*) – Address of the call target
- **retn_target** (*int or None*) – Address of the return target
- **stack_pointer** (*int*) – Value of the stack pointer

**Returns**
None

**ret**(*retn_target=None*)

Pop one or many call frames from the stack. This method is called when returning from a function in CFG recovery.

**Parameters**
**retn_target** (*int*) – The target to return to.

**Returns**
None

**dbg_repr**()

Debugging representation of this CallStack object.

**Returns**
Details of this CalLStack

**Return type**
str

**stack_suffix**(*context_sensitivity_level*)

Generate the stack suffix. A stack suffix can be used as the key to a SimRun in CFG recovery.

**Parameters**
**context_sensitivity_level** (*int*) – Level of context sensitivity.

**Returns**
A tuple of stack suffix.

**Return type**
tuple[int | None, ...]

**class** angr.state_plugins.callstack.**CallStackAction**

Bases: object

Used in callstack backtrace, which is a history of callstacks along a path, to record individual actions occurred each time the callstack is changed.

**__init__**(*callstack_hash*, *callstack_depth*, *action*, *callframe=None*, *ret_site_addr=None*)

### 10.45.2 angr.state_plugins.cgc

**class** angr.state_plugins.cgc.**SimStateCGC**

Bases: *SimStatePlugin*

This state plugin keeps track of CGC state.

**EBADF = 1**

**__init__**()

**peek_input**()

**discard_input**(*num_bytes*)

**peek_output**()

**discard_output**(*num_bytes*)

**addr_invalid**(*a*)

**get_max_sinkhole**(*length*)

Find a sinkhole which is large enough to support *length* bytes.

This uses first-fit. The first sinkhole (ordered in descending order by their address) which can hold *length* bytes is chosen. If there are more than *length* bytes in the sinkhole, a new sinkhole is created representing the remaining bytes while the old sinkhole is removed.

**add_sinkhole**(*address*, *length*)

Add a sinkhole.

Allow the possibility for the program to reuse the memory represented by the address length pair.

### 10.45.3 angr.state_plugins.debug_variables

**class** angr.state_plugins.debug_variables.**SimDebugVariable**

Bases: object

A SimDebugVariable will get dynamically created when queriyng for variable in a state with the SimDebugVariablePlugin. It features a link to the state, an address and a type.

**__init__**(*state*, *addr*, *var_type*)

**Parameters**

- **state** (SimState)
- **var_type** (*VariableType*)

**static from_cle_variable**(*state*, *cle_variable*, *dwarf_cfa*)

**Return type**
*SimDebugVariable*

**Parameters**

- **state** (SimState)
- **cle_variable** (*Variable*)

**property mem_untyped:** *SimMemView*

**property mem:** *SimMemView*

**property string:** *SimMemView*

**with_type**(*sim_type*)

**Return type**
*SimMemView*

**Parameters**
**sim_type** (SimType)

**property resolvable**

**property resolved**

**property concrete**

**store**(*value*)

**property deref:** *SimDebugVariable*

**array**(*i*)

**Return type**
*SimDebugVariable*

**member**(*member_name*)

**Return type**
*SimDebugVariable*

**Parameters**
**member_name** (*str*)

**class** angr.state_plugins.debug_variables.**SimDebugVariablePlugin**

Bases: *SimStatePlugin*

This is the plugin you'll use to interact with (global/local) program variables. These variables have a name and a visibility scope which depends on the pc address of the state. With this plugin, you can access/modify the value of such variable or find its memory address. For creating program variables, or for importing them from cle, see the knowledge plugin debug_variables. Run `p.kb.dvars.load_from_dwarf()` before using this plugin.

### Example

```
>>> p = angr.Project("various_variables", load_debug_info=True)
>>> p.kb.dvars.load_from_dwarf()
>>> state =  # navigate to the state you want
>>> state.dvars.get_variable("pointer2").deref.mem
<int (32 bits) <BV32 0x1> at 0x404020>
```

**get_variable**(*var_name*)

Returns the visible variable (if any) with name `var_name` based on the current `state.ip`.

**Return type**
*SimDebugVariable*

**Parameters**
**var_name** (*str*)

**property dwarf_cfa**

Returns the current cfa computation. Set this property to the correct value if needed.

**property dwarf_cfa_approx**

### 10.45.4 angr.state_plugins.edge_hitmap

**class** angr.state_plugins.edge_hitmap.**SimStateEdgeHitmap**

Bases: *SimStatePlugin*

A state plugin that stores AFL-style edge hitmap coverage data.

This plugin is used by the Icicle engine to track edge coverage during concrete execution. It stores the hitmap as raw bytes, which can be efficiently passed to and from the Icicle emulator.

This plugin is NOT registered as a default plugin - it must be explicitly added to states that need edge coverage tracking.

**HITMAP_SIZE = 65536**

**__init__**(*edge_hitmap=None*)

Initialize the edge hitmap plugin.

**Parameters**
**edge_hitmap** (bytes | None) – Initial edge hitmap bytes, or None to start with a zeroed hitmap.

**edge_hitmap: bytes | None**

**copy**(*memo*)

Create a copy of the plugin.

**Parameters**
**memo** – Memoization dictionary to avoid duplicate copies.

**Returns**
A new SimStateEdgeHitmap instance with a copy of the hitmap.

**merge**(*others*, *merge_conditions*, *common_ancestor=None*)

Merge multiple hitmap plugins.

For coverage tracking, we OR the hitmaps together to preserve all observed edges.

**Parameters**

- **others** – Other plugin instances to merge with.
- **merge_conditions** – Symbolic conditions for each merge branch.
- **common_ancestor** – Common ancestor plugin instance.

**Returns**
True if merge was successful.

### 10.45.5 angr.state_plugins.filesystem

**class** angr.state_plugins.filesystem.**Stat**

Bases: tuple

Stat(st_dev, st_ino, st_nlink, st_mode, st_uid, st_gid, st_rdev, st_size, st_blksize, st_blocks, st_atime, st_atimensec, st_mtime, st_mtimensec, st_ctime, st_ctimensec)

**static __new__**(*_cls*, *st_dev*, *st_ino*, *st_nlink*, *st_mode*, *st_uid*, *st_gid*, *st_rdev*, *st_size*, *st_blksize*, *st_blocks*, *st_atime*, *st_atimensec*, *st_mtime*, *st_mtimensec*, *st_ctime*, *st_ctimensec*)

Create new instance of Stat(st_dev, st_ino, st_nlink, st_mode, st_uid, st_gid, st_rdev, st_size, st_blksize, st_blocks, st_atime, st_atimensec, st_mtime, st_mtimensec, st_ctime, st_ctimensec)

**st_atime**
Alias for field number 10

**st_atimensec**
Alias for field number 11

**st_blksize**
Alias for field number 8

**st_blocks**
Alias for field number 9

**st_ctime**
Alias for field number 14

**st_ctimensec**
Alias for field number 15

**st_dev**
Alias for field number 0

**st_gid**
Alias for field number 5

**st_ino**
Alias for field number 1

**st_mode**
Alias for field number 3

**st_mtime**
Alias for field number 12

**st_mtimensec**
Alias for field number 13

**st_nlink**
Alias for field number 2

**st_rdev**
Alias for field number 6

**st_size**
Alias for field number 7

**st_uid**
Alias for field number 4

**class** angr.state_plugins.filesystem.**SimFilesystem**

Bases: *SimStatePlugin*

angr's emulated filesystem. Available as state.fs. When constructing, all parameters are optional.

**Parameters**

- **files** – A mapping from filepath to SimFile
- **pathsep** – The character used to separate path elements, default forward slash.
- **cwd** – The path of the current working directory to use

- **mountpoints** – A mapping from filepath to SimMountpoint

**Variables**

- **pathsep** – The current pathsep
- **cwd** – The current working directory, relative to the current root
- **unlinks** – A list of unlink operations, tuples of filename and simfile. Be careful, this list is shallow-copied from successor to successor, so don't mutate anything in it without copying.

**__init__**(*files=None*, *pathsep=None*, *cwd=None*, *mountpoints=None*)

**property unlinks**

**property root**

The current root directory, as an absolute path in the filesystem's original namespace, i.e. the one paths were resolved in before any chroot.

**chdir**(*path*)

Changes the current directory to the given path

**chroot**(*path*)

Changes the root directory to the given path, which is interpreted relative to the current root.

This only ever narrows what is reachable: the new root is resolved inside this filesystem, and paths (including "..") are resolved under it from then on. Contrary to Linux, where the current directory is left where it was and can therefore point outside the new root, the current directory is re-anchored inside the new root, since keeping it outside would defeat the point.

**get**(*path*)

Get a file from the filesystem. Returns a SimFile or None.

**insert**(*path*, *simfile*)

Insert a file into the filesystem. Returns whether the operation was successful.

**delete**(*path*)

Remove a file from the filesystem. Returns whether the operation was successful.

This will add a `fs_unlink` event with the path of the file and also the index into the *unlinks* list.

**mount**(*path*, *mount*)

Add a mountpoint to the filesystem.

**unmount**(*path*)

Remove a mountpoint from the filesystem.

**get_mountpoint**(*path*)

Look up the mountpoint servicing the given path.

**Returns**

A tuple of the mount and a list of path elements traversing from the mountpoint to the specified file. If no mountpoint services the path, the list traverses from the real root instead.

**class** angr.state_plugins.filesystem.**SimMount**

Bases: *SimStatePlugin*

This is the base class for "mount points" in angr's simulated filesystem. Subclass this class and give it to the filesystem to intercept all file creations and opens below the mountpoint. Since this a SimStatePlugin you may also want to implement set_state, copy, merge, etc.

**get**(*path_elements*)

Implement this function to instrument file lookups.

**Parameters**
**path_elements** – A list of path elements traversing from the mountpoint to the file

**Returns**
A SimFile, or None

**insert**(*path_elements*, *simfile*)

Implement this function to instrument file creation.

**Parameters**

- **path_elements** – A list of path elements traversing from the mountpoint to the file
- **simfile** – The file to insert

**Returns**
A bool indicating whether the insert occurred

**delete**(*path_elements*)

Implement this function to instrument file deletion.

**Parameters**
**path_elements** – A list of path elements traversing from the mountpoint to the file

**Returns**
A bool indicating whether the delete occurred

**lookup**(*sim_file*)

Look up the path of a SimFile in the mountpoint

**Parameters**
**sim_file** – A SimFile object needs to be looked up

**Returns**
A string representing the path of the file in the mountpoint Or None if the SimFile does not exist in the mountpoint

**class** angr.state_plugins.filesystem.**SimConcreteFilesystem**

Bases: *SimMount*

Abstract SimMount allowing the user to import files from some external source into the guest

**Parameters**
**pathsep** (*str*) – The host path separator character, default os.path.sep

**__init__**(*pathsep='/'*)

**class** angr.state_plugins.filesystem.**SimHostFilesystem**

Bases: *SimConcreteFilesystem*

Simulated mount that makes some piece from the host filesystem available to the guest.

**Parameters**

- **host_path** (*str*) – The path on the host to mount
- **pathsep** (*str*) – The host path separator character, default os.path.sep

**__init__**(*host_path=None*, ***kwargs*)

### 10.45.6 angr.state_plugins.gdb

**class** angr.state_plugins.gdb.**GDB**

Bases: *SimStatePlugin*

Initialize or update a state from gdb dumps of the stack, heap, registers and data (or arbitrary) segments.

**__init__**(*omit_fp=False*, *adjust_stack=False*)

**Parameters**

- **omit_fp** – The frame pointer register is used for something else. (i.e. –omit_frame_pointer)
- **adjust_stack** – Use different stack addresses than the gdb session (not recommended).

**set_stack**(*stack_dump*, *stack_top*)

Stack dump is a dump of the stack from gdb, i.e. the result of the following gdb command :

`dump binary memory [stack_dump] [begin_addr] [end_addr]`

We set the stack to the same addresses as the gdb session to avoid pointers corruption.

**Parameters**

- **stack_dump** – The dump file.
- **stack_top** – The address of the top of the stack in the gdb session.

**set_heap**(*heap_dump*, *heap_base*)

Heap dump is a dump of the heap from gdb, i.e. the result of the following gdb command:

`dump binary memory [stack_dump] [begin] [end]`

**Parameters**

- **heap_dump** – The dump file.
- **heap_base** – The start address of the heap in the gdb session.

**set_data**(*addr*, *data_dump*)

Update any data range (most likely use is the data segments of loaded objects)

**set_regs**(*regs_dump*)

Initialize register values within the state

**Parameters**

**regs_dump** – The output of `info registers` in gdb.

### 10.45.7 angr.state_plugins.globals

**class** angr.state_plugins.globals.**SimStateGlobals**

Bases: *SimStatePlugin*

**__init__**(*backer=None*)

**keys**()

**values**()

**items**()

**get**(*k*, *alt=None*)

**pop**(*k*, *alt=None*)

### 10.45.8 angr.state_plugins.heap

**class** angr.state_plugins.heap.**PTChunk**

Bases: *Chunk*

A chunk, inspired by the implementation of chunks in ptmalloc. Provides a representation of a chunk via a view into the memory plugin. For the chunk definitions and docs that this was loosely based off of, see glibc malloc/malloc.c, line 1033, as of commit 5a580643111ef6081be7b4c7bd1997a5447c903f. Alternatively, take the following link. https://sourceware.org/git/?p=glibc.git;a=blob;f=malloc/malloc.c;h=67cdfd0ad2f003964cd0f7dfe3bcd85ca98528a7;hb=5a580643111ef6081be7b4c7bd1997a5447c903f#l1033

**Variables**

- **base** – the location of the base of the chunk in memory
- **state** – the program state that the chunk is resident in
- **heap** – the heap plugin that the chunk is managed by

**__init__**(*base*, *sim_state*, *heap=None*)

**set_size**(*size*, *is_free=None*)

Use this to set the size on a chunk. When the chunk is new (such as when a free chunk is shrunk to form an allocated chunk and a remainder free chunk) it is recommended that the is_free hint be used since setting the size depends on the chunk's freeness, and vice versa.

**Parameters**

- **size** – size of the chunk
- **is_free** – boolean indicating the chunk's freeness

**set_prev_freeness**(*is_free*)

Sets (or unsets) the flag controlling whether the previous chunk is free.

**Parameters**

**is_free** – if True, sets the previous chunk to be free; if False, sets it to be allocated

**is_prev_free**()

Returns a concrete state of the flag indicating whether the previous chunk is free or not. Issues a warning if that flag is symbolic and has multiple solutions, and then assumes that the previous chunk is free.

**Returns**

True if the previous chunk is free; False otherwise

**prev_size**()

Returns the size of the previous chunk, masking off what would be the flag bits if it were in the actual size field. Performs NO CHECKING to determine whether the previous chunk size is valid (for example, when the previous chunk is not free, its size cannot be determined).

**next_chunk**()

Returns the chunk immediately following (and adjacent to) this one, if it exists.

**Returns**

The following chunk, or None if applicable

**prev_chunk**()

Returns the chunk immediately prior (and adjacent) to this one, if that chunk is free. If the prior chunk is not free, then its base cannot be located and this method raises an error.

**Returns**
If possible, the previous chunk; otherwise, raises an error

**fwd_chunk**()

Returns the chunk following this chunk in the list of free chunks. If this chunk is not free, then it resides in no such list and this method raises an error.

**Returns**
If possible, the forward chunk; otherwise, raises an error

**bck_chunk**()

Returns the chunk backward from this chunk in the list of free chunks. If this chunk is not free, then it resides in no such list and this method raises an error.

**Returns**
If possible, the backward chunk; otherwise, raises an error

**class** angr.state_plugins.heap.**PTChunkIterator**

Bases: object

**__init__**(*chunk*, *cond=<function PTChunkIterator.<lambda>>*)

**class** angr.state_plugins.heap.**SimHeapBase**

Bases: *SimStatePlugin*

This is the base heap class that all heap implementations should subclass. It defines a few handlers for common heap functions (the libc memory management functions). Heap implementations are expected to override these functions regardless of whether they implement the SimHeapLibc interface. For an example, see the SimHeapBrk implementation, which is based on the original libc SimProcedure implementations.

**Variables**

- **heap_base** – the address of the base of the heap in memory
- **heap_size** – the maximum size of the main memory region managed by the heap in memory. Only the part of it that has actually been handed out is mapped; see _ensure_mapped.
- **mmap_base** – the address of the region from which large mmap allocations will be made

**__init__**(*heap_base=None*, *heap_size=None*)

**class** angr.state_plugins.heap.**SimHeapBrk**

Bases: *SimHeapBase*

SimHeapBrk represents a trivial heap implementation based on the Unix *brk* system call. This type of heap stores virtually no metadata, so it is up to the user to determine when it is safe to release memory. This also means that it does not properly support standard heap operations like *realloc*.

This heap implementation is a holdover from before any more proper implementations were modelled. At the time, various libc (or win32) SimProcedures handled the heap in the same way that this plugin does now. To make future heap implementations plug-and-playable, they should implement the necessary logic themselves, and dependent SimProcedures should invoke a method by the same name as theirs (prepended with an underscore) upon the heap plugin. Depending on the heap implementation, if the method is not supported, an error should be raised.

Out of consideration for the original way the heap was handled, this plugin implements functionality for all relevant SimProcedures (even those that would not normally be supported together in a single heap implementation).

**Variables**
**heap_location** – the address of the top of the heap, bounding the allocations made starting from *heap_base*

**__init__**(*heap_base=None*, *heap_size=None*)

**allocate**(*sim_size*)

The actual allocation primitive for this heap implementation. Increases the position of the break to allocate space. Has no guards against the heap growing too large.

**Parameters**
**sim_size** – a size specifying how much to increase the break pointer by

**Returns**
a pointer to the previous break position, above which there is now allocated space

**release**(*sim_size*)

The memory release primitive for this heap implementation. Decreases the position of the break to deallocate space. Guards against releasing beyond the initial heap base.

The mapped extent of the heap is deliberately not shrunk here. Unmapping the released pages would discard their contents, so a release followed by an allocation would hand back blank memory instead of the old bytes, which is a behavior change; and since the extent only ever grows to the high-water mark of the break, keeping it costs nothing beyond what the program already asked for.

**Parameters**
**sim_size** – a size specifying how much to decrease the break pointer by (may be symbolic or not)

**class** angr.state_plugins.heap.**SimHeapLibc**

Bases: *SimHeapBase*

A class of heap that implements the major libc heap management functions.

**malloc**(*sim_size*)

A somewhat faithful implementation of libc *malloc*.

**Parameters**
**sim_size** – the amount of memory (in bytes) to be allocated

**Returns**
the address of the allocation, or a NULL pointer if the allocation failed

**free**(*ptr*)

A somewhat faithful implementation of libc *free*.

**Parameters**
**ptr** – the location in memory to be freed

**calloc**(*sim_nmemb*, *sim_size*)

A somewhat faithful implementation of libc *calloc*.

**Parameters**

- **sim_nmemb** – the number of elements to allocated
- **sim_size** – the size of each element (in bytes)

**Returns**
the address of the allocation, or a NULL pointer if the allocation failed

**realloc**(*ptr*, *size*)

A somewhat faithful implementation of libc *realloc*.

**Parameters**

- **ptr** – the location in memory to be reallocated
- **size** – the new size desired for the allocation

**Returns**

the address of the allocation, or a NULL pointer if the allocation was freed or if no new allocation was made

**class** angr.state_plugins.heap.**SimHeapPTMalloc**

Bases: *SimHeapFreelist*

A freelist-style heap implementation inspired by ptmalloc. The chunks used by this heap contain heap metadata in addition to user data. While the real-world ptmalloc is implemented using multiple lists of free chunks (corresponding to their different sizes), this more basic model uses a single list of chunks and searches for free chunks using a first-fit algorithm.

**NOTE:** The plugin must be registered using `register_plugin` with name `heap` in order to function properly.

**Variables**

- **heap_base** – the address of the base of the heap in memory
- **heap_size** – the total size of the main memory region managed by the heap in memory
- **mmap_base** – the address of the region from which large mmap allocations will be made
- **free_head_chunk** – the head of the linked list of free chunks in the heap

**__init__**(*heap_base=None*, *heap_size=None*)

**chunk_from_mem**(*ptr*)

Given a pointer to a user payload, return the base of the chunk associated with that payload (i.e. the chunk pointer). Returns None if ptr is null.

**Parameters**

**ptr** – a pointer to the base of a user payload in the heap

**Returns**

a pointer to the base of the associated heap chunk, or None if ptr is null

### angr.state_plugins.heap.heap_base

**class** angr.state_plugins.heap.heap_base.**SimHeapBase**

Bases: *SimStatePlugin*

This is the base heap class that all heap implementations should subclass. It defines a few handlers for common

heap functions (the libc memory management functions). Heap implementations are expected to override these functions regardless of whether they implement the SimHeapLibc interface. For an example, see the SimHeapBrk implementation, which is based on the original libc SimProcedure implementations.

**Variables**

- **heap_base** – the address of the base of the heap in memory
- **heap_size** – the maximum size of the main memory region managed by the heap in memory. Only the part of it that has actually been handed out is mapped; see `_ensure_mapped`.
- **mmap_base** – the address of the region from which large mmap allocations will be made

**__init__**(*heap_base=None*, *heap_size=None*)

### angr.state_plugins.heap.heap_brk

**class** angr.state_plugins.heap.heap_brk.**SimHeapBrk**

Bases: *SimHeapBase*

SimHeapBrk represents a trivial heap implementation based on the Unix *brk* system call. This type of heap stores virtually no metadata, so it is up to the user to determine when it is safe to release memory. This also means that it does not properly support standard heap operations like *realloc*.

This heap implementation is a holdover from before any more proper implementations were modelled. At the time, various libc (or win32) SimProcedures handled the heap in the same way that this plugin does now. To make future heap implementations plug-and-playable, they should implement the necessary logic themselves, and dependent SimProcedures should invoke a method by the same name as theirs (prepended with an underscore) upon the heap plugin. Depending on the heap implementation, if the method is not supported, an error should be raised.

Out of consideration for the original way the heap was handled, this plugin implements functionality for all relevant SimProcedures (even those that would not normally be supported together in a single heap implementation).

**Variables**
**heap_location** – the address of the top of the heap, bounding the allocations made starting from *heap_base*

**__init__**(*heap_base=None*, *heap_size=None*)

**allocate**(*sim_size*)

The actual allocation primitive for this heap implementation. Increases the position of the break to allocate space. Has no guards against the heap growing too large.

**Parameters**
**sim_size** – a size specifying how much to increase the break pointer by

**Returns**
a pointer to the previous break position, above which there is now allocated space

**release**(*sim_size*)

The memory release primitive for this heap implementation. Decreases the position of the break to deallocate space. Guards against releasing beyond the initial heap base.

The mapped extent of the heap is deliberately not shrunk here. Unmapping the released pages would discard their contents, so a release followed by an allocation would hand back blank memory instead of the old bytes, which is a behavior change; and since the extent only ever grows to the high-water mark of the break, keeping it costs nothing beyond what the program already asked for.

**Parameters**
**sim_size** – a size specifying how much to decrease the break pointer by (may be symbolic or not)

### angr.state_plugins.heap.heap_freelist

**class** angr.state_plugins.heap.heap_freelist.**Chunk**

Bases: object

The sort of chunk as would typically be found in a freelist-style heap implementation. Provides a representation of a chunk via a view into the memory plugin. Chunks may be adjacent, in different senses, to as many as four other chunks. For any given chunk, two of these chunks are adjacent to it in memory, and are referred to as the "previous" and "next" chunks throughout this implementation. For any given free chunk, there may also be two significant chunks that are adjacent to it in some linked list of free chunks. These chunks are referred to the "backward" and "forward" chunks relative to the chunk in question.

**Variables**

- **base** – the location of the base of the chunk in memory
- **state** – the program state that the chunk is resident in

**__init__**(*base*, *sim_state*)

**get_size**()
Returns the actual size of a chunk (as opposed to the entire size field, which may include some flags).

**get_data_size**()
Returns the size of the data portion of a chunk.

**set_size**(*size*)
Sets the size of the chunk, preserving any flags.

**data_ptr**()
Returns the address of the payload of the chunk.

**is_free**()
Returns a concrete determination as to whether the chunk is free.

**next_chunk**()
Returns the chunk immediately following (and adjacent to) this one.

**prev_chunk**()
Returns the chunk immediately prior (and adjacent) to this one.

**fwd_chunk**()
Returns the chunk following this chunk in the list of free chunks.

**set_fwd_chunk**(*fwd*)
Sets the chunk following this chunk in the list of free chunks.

**Parameters**
**fwd** – the chunk to follow this chunk in the list of free chunks

**bck_chunk**()
Returns the chunk backward from this chunk in the list of free chunks.

**set_bck_chunk**(*bck*)

Sets the chunk backward from this chunk in the list of free chunks.

**Parameters**
**bck** – the chunk to precede this chunk in the list of free chunks

class angr.state_plugins.heap.heap_freelist.**SimHeapFreelist**

Bases: *SimHeapLibc*

A freelist-style heap implementation. Distinguishing features of such heaps include chunks containing heap metadata in addition to user data and at least (but often more than) one linked list of free chunks.

**chunks**()

Returns an iterator over all the chunks in the heap.

**allocated_chunks**()

Returns an iterator over all the allocated chunks in the heap.

**free_chunks**()

Returns an iterator over all the free chunks in the heap.

**chunk_from_mem**(*ptr*)

Given a pointer to a user payload, return the chunk associated with that payload.

**Parameters**
**ptr** – a pointer to the base of a user payload in the heap

**Returns**
the associated heap chunk

**print_heap_state**()

**print_all_chunks**()

### angr.state_plugins.heap.heap_libc

class angr.state_plugins.heap.heap_libc.**SimHeapLibc**

Bases: *SimHeapBase*

A class of heap that implements the major libc heap management functions.

**malloc**(*sim_size*)

A somewhat faithful implementation of libc *malloc*.

**Parameters**
**sim_size** – the amount of memory (in bytes) to be allocated

**Returns**
the address of the allocation, or a NULL pointer if the allocation failed

**free**(*ptr*)

A somewhat faithful implementation of libc *free*.

**Parameters**
**ptr** – the location in memory to be freed

**calloc**(*sim_nmemb*, *sim_size*)

A somewhat faithful implementation of libc *calloc*.

**Parameters**

- **sim_nmemb** – the number of elements to allocated
- **sim_size** – the size of each element (in bytes)

**Returns**
the address of the allocation, or a NULL pointer if the allocation failed

**realloc**(*ptr*, *size*)

A somewhat faithful implementation of libc *realloc*.

**Parameters**

- **ptr** – the location in memory to be reallocated
- **size** – the new size desired for the allocation

**Returns**
the address of the allocation, or a NULL pointer if the allocation was freed or if no new allocation was made

### angr.state_plugins.heap.heap_ptmalloc

**class** angr.state_plugins.heap.heap_ptmalloc.**PTChunk**

Bases: *Chunk*

A chunk, inspired by the implementation of chunks in ptmalloc. Provides a representation of a chunk via a view into the memory plugin. For the chunk definitions and docs that this was loosely based off of, see glibc malloc/malloc.c, line 1033, as of commit 5a580643111ef6081be7b4c7bd1997a5447c903f. Alternatively, take the following link. https://sourceware.org/git/?p=glibc.git;a=blob;f=malloc/malloc.c;h=67cdfd0ad2f003964cd0f7dfe3bcd85ca98528a7;hb=5a580643111ef6081be7b4c7bd1997a5447c903f#l1033

**Variables**

- **base** – the location of the base of the chunk in memory
- **state** – the program state that the chunk is resident in
- **heap** – the heap plugin that the chunk is managed by

**__init__**(*base*, *sim_state*, *heap=None*)

**set_size**(*size*, *is_free=None*)

Use this to set the size on a chunk. When the chunk is new (such as when a free chunk is shrunk to form an allocated chunk and a remainder free chunk) it is recommended that the is_free hint be used since setting the size depends on the chunk's freeness, and vice versa.

**Parameters**

- **size** – size of the chunk
- **is_free** – boolean indicating the chunk's freeness

**set_prev_freeness**(*is_free*)

Sets (or unsets) the flag controlling whether the previous chunk is free.

**Parameters**
**is_free** – if True, sets the previous chunk to be free; if False, sets it to be allocated

**is_prev_free**()

Returns a concrete state of the flag indicating whether the previous chunk is free or not. Issues a warning if that flag is symbolic and has multiple solutions, and then assumes that the previous chunk is free.

**Returns**
True if the previous chunk is free; False otherwise

**prev_size**()

Returns the size of the previous chunk, masking off what would be the flag bits if it were in the actual size field. Performs NO CHECKING to determine whether the previous chunk size is valid (for example, when the previous chunk is not free, its size cannot be determined).

**next_chunk**()

Returns the chunk immediately following (and adjacent to) this one, if it exists.

**Returns**
The following chunk, or None if applicable

**prev_chunk**()

Returns the chunk immediately prior (and adjacent) to this one, if that chunk is free. If the prior chunk is not free, then its base cannot be located and this method raises an error.

**Returns**
If possible, the previous chunk; otherwise, raises an error

**fwd_chunk**()

Returns the chunk following this chunk in the list of free chunks. If this chunk is not free, then it resides in no such list and this method raises an error.

**Returns**
If possible, the forward chunk; otherwise, raises an error

**bck_chunk**()

Returns the chunk backward from this chunk in the list of free chunks. If this chunk is not free, then it resides in no such list and this method raises an error.

**Returns**
If possible, the backward chunk; otherwise, raises an error

**class** angr.state_plugins.heap.heap_ptmalloc.**PTChunkIterator**

Bases: object

**__init__**(*chunk*, *cond=<function PTChunkIterator.<lambda>>*)

**class** angr.state_plugins.heap.heap_ptmalloc.**SimHeapPTMalloc**

Bases: *SimHeapFreelist*

A freelist-style heap implementation inspired by ptmalloc. The chunks used by this heap contain heap metadata in addition to user data. While the real-world ptmalloc is implemented using multiple lists of free chunks (corresponding to their different sizes), this more basic model uses a single list of chunks and searches for free chunks using a first-fit algorithm.

**NOTE:** The plugin must be registered using `register_plugin` with name `heap` in order to function properly.

**Variables**

- **heap_base** – the address of the base of the heap in memory
- **heap_size** – the total size of the main memory region managed by the heap in memory
- **mmap_base** – the address of the region from which large mmap allocations will be made
- **free_head_chunk** – the head of the linked list of free chunks in the heap

**__init__**(*heap_base=None*, *heap_size=None*)

**chunk_from_mem**(*ptr*)

Given a pointer to a user payload, return the base of the chunk associated with that payload (i.e. the chunk pointer). Returns None if ptr is null.

**Parameters**
**ptr** – a pointer to the base of a user payload in the heap

**Returns**
a pointer to the base of the associated heap chunk, or None if ptr is null

#### angr.state_plugins.heap.utils

angr.state_plugins.heap.utils.**concretize**(*x*, *solver*, *sym_handler*)

For now a lot of naive concretization is done when handling heap metadata to keep things manageable. This idiom showed up a lot as a result, so to reduce code repetition this function uses a callback to handle the one or two operations that varied across invocations.

**Parameters**

- **x** – the item to be concretized
- **solver** – the solver to evaluate the item with
- **sym_handler** – the handler to be used when the item may take on more than one value

**Returns**
a concrete value for the item

### 10.45.9 angr.state_plugins.history

**class** angr.state_plugins.history.**SimStateHistory**

Bases: *SimStatePlugin*

This class keeps track of historically-relevant information for paths.

**__init__**(*parent=None*, *clone=None*)

**property addr**

**trim**()

Discard the ancestry of this state.

**filter_actions**(*start_block_addr=None*, *end_block_addr=None*, *block_stmt=None*, *insn_addr=None*, *read_from=None*, *write_to=None*)

Filter self.actions based on some common parameters.

[start_block_addr, end_block_addr]

**Parameters**

- **start_block_addr** – Only return actions generated in blocks starting at this address.
- **end_block_addr** – Only return actions generated in blocks ending at this address.
- **block_stmt** – Only return actions generated in the nth statement of each block.
- **insn_addr** – Only return actions generated in the assembly instruction at this address.
- **read_from** – Only return actions that perform a read from the specified location.
- **write_to** – Only return actions that perform a write to the specified location.

Notes: If IR optimization is turned on, reads and writes may not occur in the instruction they originally came from. Most commonly, If a register is read from twice in the same block, the second read will not happen, instead reusing the temp the value is already stored in.

Valid values for read_from and write_to are the string literals 'reg' or 'mem' (matching any read or write to registers or memory, respectively), any string (representing a read or write to the named register), and any integer (representing a read or write to the memory at this address).

**demote**()

Demotes this history node, causing it to drop the strong state reference.

**reachable**()

**add_event**(*event_type*, ***kwargs*)

**add_action**(*action*)

**extend_actions**(*new_actions*)

**subscribe_actions**()

**property recent_constraints**

**property recent_actions**

**property block_count**

**property lineage**

**property parents**

**property events:** Reversible[*SimEvent*]

**property actions:** Reversible[*SimAction*]

**property jumpkinds:** Reversible[str]

**property jump_guards:** Reversible[Bool]

**property jump_targets**

**property jump_sources**

**property descriptions:** Reversible[str]

**property bbl_addrs:** Reversible[int]

**property ins_addrs:** Reversible[int]

**property stack_actions**

**property last_edge_hitmap:** bytes | None

Returns the last edge hitmap in the history chain, or None if there is no edge hitmap.

**closest_common_ancestor**(*other*)

Find the common ancestor between this history node and 'other'.

**Parameters**
**other** – the PathHistory to find a common ancestor with.

**Returns**
the common ancestor SimStateHistory, or None if there isn't one

constraints_since(*other*)

Returns the constraints that have been accumulated since *other*.

**Parameters**
**other** – a prior PathHistory object

**Returns**
a list of constraints

make_child()

class angr.state_plugins.history.**TreeIter**

Bases: object

__init__(*start*, *end=None*)

property **hardcopy**

count(*v*)

Count occurrences of value v in the entire history. Note that the subclass must implement the __reversed__ method, otherwise an exception will be thrown. :type v: object :param v: The value to look for :return: The number of occurrences :rtype: int

class angr.state_plugins.history.**HistoryIter**

Bases: *TreeIter*

class angr.state_plugins.history.**LambdaAttrIter**

Bases: *TreeIter*

__init__(*start*, *f*, ***kwargs*)

class angr.state_plugins.history.**LambdaIterIter**

Bases: *LambdaAttrIter*

__init__(*start*, *f*, *reverse=True*, ***kwargs*)

### 10.45.10 angr.state_plugins.icicle

class angr.state_plugins.icicle.**IcicleStateTranslationData**

Bases: object

Represents the saved information needed to convert an Icicle state back to an angr state.

**registers**: set[str]

**mapped_pages**: set[int]

**writable_pages**: set[int]

**explicit_page_metadata**: dict[int, int | None]

**initial_cpu_icount**: int

**icicle_arch**: str

__init__(*registers*, *mapped_pages*, *writable_pages*, *explicit_page_metadata*, *initial_cpu_icount*, *icicle_arch*)

**Parameters**

- **registers** (*set[str]*)
- **mapped_pages** (*set[int]*)
- **writable_pages** (*set[int]*)
- **explicit_page_metadata** (*dict[int, int | None]*)
- **initial_cpu_icount** (*int*)
- **icicle_arch** (*str*)

**Return type**
None

**class** angr.state_plugins.icicle.**IcicleVMRef**

Bases: object

Holder shared by reference across plugin copies.

Lets multiple SimStateIcicle plugins point at the same VM and observe each other's advancements via *generation*: each successful engine run bumps *generation*, invalidating any plugin still holding the prior value.

**vm: Icicle**

**generation: int = 0**

**__init__**(*vm*, *generation=0*)

**Parameters**
- **vm** (*Icicle*)
- **generation** (*int*)

**Return type**
None

**class** angr.state_plugins.icicle.**SimStateIcicle**

Bases: *SimStatePlugin*

Engine-internal plugin for IcicleEngine continuation detection.

Attached to states produced by `IcicleEngine.process()`. Owns the VM and the metadata the engine needs to decide whether the next call is a lightweight continuation or requires a full snapshot restore.

**__init__**(*vm_ref=None*, *generation=None*, *base_translation_data=None*, *translation_data=None*, *dirty_pages=None*)

**Parameters**
- **vm_ref** (*IcicleVMRef | None*)
- **generation** (*int | None*)
- **base_translation_data** (*IcicleStateTranslationData | None*)
- **translation_data** (*IcicleStateTranslationData | None*)
- **dirty_pages** (*set[int] | None*)

**property is_live: bool**

True when the VM is still positioned where this state last left it.

### 10.45.11 angr.state_plugins.inspect

**class** angr.state_plugins.inspect.**EventType**

Bases: StrEnum

Event types for breakpoints.

**VEX_LIFT** = 'vex_lift'

**MEM_READ** = 'mem_read'

**MEM_WRITE** = 'mem_write'

**ADDRESS_CONCRETIZATION** = 'address_concretization'

**REG_READ** = 'reg_read'

**REG_WRITE** = 'reg_write'

**TMP_READ** = 'tmp_read'

**TMP_WRITE** = 'tmp_write'

**EXPR** = 'expr'

**STATEMENT** = 'statement'

**INSTRUCTION** = 'instruction'

**IRSB** = 'irsb'

**CONSTRAINTS** = 'constraints'

**EXIT** = 'exit'

**FORK** = 'fork'

**SYMBOLIC_VARIABLE** = 'symbolic_variable'

**CALL** = 'call'

**RETURN** = 'return'

**SIMPROCEDURE** = 'simprocedure'

**DIRTY** = 'dirty'

**SYSCALL** = 'syscall'

**CFG_HANDLE_JOB** = 'cfg_handle_job'

**VFG_HANDLE_SUCCESSOR** = 'vfg_handle_successor'

**ENGINE_PROCESS** = 'engine_process'

**MEMORY_PAGE_MAP** = 'memory_page_map'

**__new__**(*value*)

class angr.state_plugins.inspect.**InspectAttrs**

Bases: object

Per-event attributes published by the inspect machinery while a breakpoint is firing.

Each field is set on the active state before any matching breakpoint is checked, then cleared (back to None) after the event completes. Breakpoint actions read and write these fields through `state.inspect.attrs` to observe or override the in-flight event.

- **dirty_result** (*Any*)
- **sim_engine** (*Any*)
- **sim_successors** (*Any*)
- **mapped_page** (*Any*)
- **mapped_address** (*Any*)

**Return type**
None

class angr.state_plugins.inspect.**When**

Bases: StrEnum

When to trigger breakpoints.

**BEFORE** = 'before'

**AFTER** = 'after'

**BOTH** = 'both'

**__new__**(*value*)

type angr.state_plugins.inspect.**Action** = Callable[[*SimState*], None]

angr.state_plugins.inspect.**BP_IPDB**(*state*)

**Return type**
None

**Parameters**
**state** (SimState)

angr.state_plugins.inspect.**BP_IPYTHON**(*state*)

**Return type**
None

**Parameters**
**state** (SimState)

class angr.state_plugins.inspect.**BP**

Bases: object

A breakpoint.

**__init__**(*when=When.BEFORE*, *enabled=True*, *condition=None*, *action=<function BP_IPDB>*, ***kwargs*)

**Parameters**

- **when** (When)
- **enabled** (*bool*)
- **condition** (*Callable[[SimState], bool] | None*)
- **action** (Action)
- **kwargs** (*dict[str, Any]*)

**check**(*state*, *when*)

Checks state *state* to see if the breakpoint should fire.

**Parameters**

- **state** (*SimState*) – The state.
- **when** (*When*) – Whether the check is happening before or after the event.

**Return type**
bool

**Returns**
A boolean representing whether the checkpoint should fire.

**fire**(*state*)

Trigger the breakpoint.

**Parameters**
**state** (*SimState*) – The state.

**class** angr.state_plugins.inspect.**SimInspector**

Bases: *SimStatePlugin*

The breakpoint interface, used to instrument execution. For usage information, look here: https://docs.angr.io/core-concepts/simulation#breakpoints

**BP_AFTER = 'after'**

**BP_BEFORE = 'before'**

**BP_BOTH = 'both'**

**__init__**()

**action**(*event_type*, *when*, ***kwargs*)

Called from within the engine when events happens. This function checks all breakpoints registered for that event and fires the ones whose conditions match.

**Return type**
None

**Parameters**

- **event_type** (EventType)
- **when** (When)
- **kwargs** (*dict[str, Any]*)

**make_breakpoint**(*event_type*, *when=When.BEFORE*, *enabled=True*, *condition=None*, *action=<function BP_IPDB>*, ***kwargs*)

Creates and adds a breakpoint which would trigger on *event_type*. Additional arguments are passed to the *BP* constructor.

**Returns**
The created breakpoint, so that it can be removed later.

**Parameters**

- **event_type** (EventType)
- **when** (When)

- **enabled** (*bool*)
- **condition** (*Callable[[SimState], bool] | None*)
- **action** (*Action*)
- **kwargs** (*dict[str, Any]*)

**b**(*event_type*, *when=When.BEFORE*, *enabled=True*, *condition=None*, *action=<function BP_IPDB>*, ***kwargs*)

Creates and adds a breakpoint which would trigger on *event_type*. Additional arguments are passed to the *BP* constructor.

**Returns**
The created breakpoint, so that it can be removed later.

**Parameters**

- **event_type** (*EventType*)
- **when** (*When*)
- **enabled** (*bool*)
- **condition** (*Callable[[SimState], bool] | None*)
- **action** (*Action*)
- **kwargs** (*dict[str, Any]*)

**add_breakpoint**(*event_type*, *bp*)

Adds a breakpoint which would trigger on *event_type*.

**Parameters**

- **event_type** (*EventType*) – The event type to trigger on
- **bp** (*BP*) – The breakpoint

**Return type**
None

**Returns**
The created breakpoint.

**remove_breakpoint**(*event_type*, *bp=None*, *filter_func=None*)

Removes a breakpoint.

**Parameters**

- **bp** (*BP* | None) – The breakpoint to remove.
- **filter_func** (Callable[[*BP*], bool] | None) – A filter function to specify whether each breakpoint should be removed or not.
- **event_type** (*EventType*)

**Return type**
None

**downsize**()

Reset event-specific attributes on this plugin instance to save memory. This method is supposed to be called by breakpoint implementors. A typical workflow looks like the following:

```
>>> # Add `attr0` and `attr1` via the inspect machinery
>>> self.state.inspect(xxxxxx, attr0=yyyy, attr1=zzzz)
>>> # Get new attributes out of SimInspect in case they are modified by the user
>>> new_attr0 = self.state.inspect.attrs.attr0
>>> new_attr1 = self.state.inspect.attrs.attr1
>>> # Reset them
>>> self.state.inspect.downsize()
```

### 10.45.12 angr.state_plugins.javavm_classloader

**class** angr.state_plugins.javavm_classloader.**SimJavaVmClassloader**

Bases: *SimStatePlugin*

JavaVM Classloader is used as an interface for resolving and initializing Java classes.

**__init__**(*initialized_classes=None*)

**get_class**(*class_name*, *init_class=False*, *step_func=None*)

Get a class descriptor for the class.

**Parameters**

- **class_name** (*str*) – Name of class.
- **init_class** (*bool*) – Whether the class initializer <clinit> should be executed.
- **step_func** (*func*) – Callback function executed at every step of the simulation manager during the execution of the main <clinit> method

**get_superclass**(*class_*)

Get the superclass of the class.

**get_class_hierarchy**(*base_class*)

Walks up the class hierarchy and returns a list of all classes between base class (inclusive) and java.lang.Object (exclusive).

**is_class_initialized**(*class_*)

Indicates whether the classes initializing method <clinit> was already executed on the state.

**init_class**(*class_*, *step_func=None*)

This method simulates the loading of a class by the JVM, during which parts of the class (e.g. static fields) are initialized. For this, we run the class initializer method <clinit> (if available) and update the state accordingly.

**Note: Initialization is skipped, if the class has already been** initialized (or if it's not loaded in CLE).

**property initialized_classes**

List of all initialized classes.

### 10.45.13 angr.state_plugins.jni_references

**class** angr.state_plugins.jni_references.**SimStateJNIReferences**

Bases: *SimStatePlugin*

Management of the mapping between opaque JNI references and the corresponding Java objects.

**__init__**(*local_refs=None*, *global_refs=None*)

**lookup**(*opaque_ref*)

Lookups the object that was used for creating the reference.

**create_new_reference**(*obj*, *global_ref=False*)

Create a new reference thats maps to the given object.

**Parameters**

- **obj** – Object which gets referenced.
- **global_ref** (*bool*) – Whether a local or global reference is created.

**clear_local_references**()

Clear all local references.

**delete_reference**(*opaque_ref*, *global_ref=False*)

Delete the stored mapping of a reference.

**Parameters**

- **opaque_ref** – Reference which should be removed.
- **global_ref** (*bool*) – Whether opaque_ref is a local or global reference.

### 10.45.14 angr.state_plugins.libc

**class** angr.state_plugins.libc.**SimStateLibc**

Bases: *SimStatePlugin*

This state plugin keeps track of various libc stuff:

```
LOCALE_ARRAY = [b'\x00\x00', b'\x00\x00', b'\x00\x00', b'\x00\x00', b'\x00\x00',
b'\x00\x00',
```

TOLOWER_LOC_ARRAY = [128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139,
140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156,
157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173,
174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190,
191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207,
208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224,
225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241,
242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 4294967295, 0, 1,

### 10.45.15 angr.state_plugins.light_registers

class angr.state_plugins.light_registers.**SimLightRegisters**

Bases: *SimStatePlugin*

**__init__**(*reg_map=None*, *registers=None*)

**resolve_register**(*offset*, *size*)

**load**(*offset*, *size=None*, ***kwargs*)

**store**(*offset*, *value*, *size=None*, *endness=None*, ***kwargs*)

### 10.45.16 angr.state_plugins.log

class angr.state_plugins.log.**SimStateLog**

Bases: *SimStatePlugin*

**__init__**(*log=None*)

**property actions**

**add_event**(*event_type*, ***kwargs*)

**add_action**(*action*)

**extend_actions**(*new_actions*)

**events_of_type**(*event_type*)

**actions_of_type**(*action_type*)

**property fresh_constraints**

**clear**()

### 10.45.17 angr.state_plugins.loop_data

class angr.state_plugins.loop_data.**SimStateLoopData**

Bases: *SimStatePlugin*

This class keeps track of loop-related information for states. Note that we have 2 counters for loop iterations (trip counts): the first recording the number of times one of the back edges (or continue edges) of a loop is taken, whereas the second recording the number of times the loop header (or loop entry) is executed. These 2 counters may differ since compilers usually optimize loops hence completely change the loop structure at the binary level. This is supposed to be used with *LoopSeer* exploration technique, which monitors loop execution. For the moment, the only thing we want to analyze is loop trip counts, but nothing prevents us from extending this plugin for other loop analyses.

**__init__**(*back_edge_trip_counts=None*, *header_trip_counts=None*, *current_loop=None*)

**Parameters**

- **back_edge_trip_counts** – Dictionary that stores back edge based trip counts for each loop. Keys are address of loop headers.
- **header_trip_counts** – Dictionary that stores header based trip counts for each loop. Keys are address of loop headers.
- **current_loop** – List of currently running loops. Each element is a tuple (loop object, list of loop exits).

### 10.45.18 angr.state_plugins.plugin

**class** angr.state_plugins.plugin.**SimStatePlugin**

Bases: object

This is a base class for SimState plugins. A SimState plugin will be copied along with the state when the state is branched. They are intended to be used for things such as tracking open files, tracking heap details, and providing storage and persistence for SimProcedures.

**__init__**()

**Return type**
None

**state:** *SimState*[Any, Any]

**set_state**(*state*)

Sets a new state (for example, if the state has been branched)

**Return type**
None

**static memo**[*S_co*](*f*)

A decorator function you should apply to copy

**Return type**
_CopyFunc[S_co]

**Parameters**
**f** (*Callable[[Any, dict[int, Any]], S_co]*)

**copy**(*_memo*)

Should return a copy of the plugin without any state attached. Should check the memo first, and add itself to memo if it ends up making a new copy.

In order to simplify using the memo, you should annotate implementations of this function with SimStatePlugin.memo

The base implementation of this function constructs a new instance of the plugin's class without calling its initializer. If you super-call down to it, make sure you instantiate all the fields in your copy method!

**Parameters**

- **memo** – A dictionary mapping object identifiers (id(obj)) to their copied instance. Use this to avoid infinite recursion and diverged copies.
- **_memo** (*dict[int, Any]*)

**Return type**
*SimStatePlugin*

**merge**(*others*, *merge_conditions*, *common_ancestor=None*)

Should merge the state plugin with the provided others. This will be called by state.merge() after copying the target state, so this should mutate the current instance to merge with the others.

Note that when multiple instances of a single plugin object (for example, a file) are referenced in the state, it is important that merge only ever be called once. This should be solved by designating one of the plugin's referees as the "real owner", who should be the one to actually merge it. This technique doesn't work to resolve the similar issue that arises during copying because merging doesn't produce a new reference to insert.

There will be n `others` and n+1 merge conditions, since the first condition corresponds to self. To match elements up to conditions, say `zip([self] + others, merge_conditions)`

When implementing this, make sure that you "deepen" both `others` and `common_ancestor` before calling sub-elements' merge methods, e.g.

```
self.foo.merge(
    [o.foo for o in others],
    merge_conditions,
    common_ancestor=common_ancestor.foo if common_ancestor is not None else None
)
```

During static analysis, merge_conditions can be None, in which case you should use `state.solver.union(values)`. TODO: fish please make this less bullshit

There is a utility `claripy.ite_cases` which will help with constructing arbitrarily large merged ASTs. Use it like `self.bar = claripy.ite_cases(zip(conditions[1:], [o.bar for o in others]), self.bar)`

**Parameters**

- **others** – the other state plugins to merge with
- **merge_conditions** – a symbolic condition for each of the plugins
- **common_ancestor** – a common ancestor of this plugin and the others being merged

**Returns**
True if the state plugins are actually merged.

**Return type**
bool

**classmethod register_default**(*name*, *xtr=None*)

**Return type**
None

**Parameters**

- **name** (*str*)
- **xtr** (*type[SimStatePlugin] | str | None*)

**init_state**()

Use this function to perform any initialization on the state at plugin-add time

**Return type**
None

### 10.45.19 angr.state_plugins.posix

**class** angr.state_plugins.posix.**PosixDevFS**

Bases: *SimMount*

**class** angr.state_plugins.posix.**PosixProcFS**

Bases: *SimMount*

The virtual file system mounted at /proc (as of now, on Linux).

**class** angr.state_plugins.posix.**SimSystemPosix**

Bases: *SimStatePlugin*

Data storage and interaction mechanisms for states with an environment conforming to posix. Available as `state.posix`.

**SIG_BLOCK = 0**

**SIG_UNBLOCK = 1**

**SIG_SETMASK = 2**

**EPERM = 1**

**ENOENT = 2**

**ESRCH = 3**

**EINTR = 4**

**EIO = 5**

**ENXIO = 6**

**E2BIG = 7**

**ENOEXEC = 8**

**EBADF = 9**

**ECHILD = 10**

**EAGAIN = 11**

**ENOMEM = 12**

**EACCES = 13**

**EFAULT = 14**

**ENOTBLK = 15**

**EBUSY = 16**

**EEXIST = 17**

**EXDEV = 18**

**ENODEV = 19**

**ENOTDIR = 20**

**EISDIR = 21**

**EINVAL = 22**

**ENFILE = 23**

**EMFILE = 24**

**ENOTTY = 25**

**ETXTBSY = 26**

**EFBIG = 27**

**ENOSPC = 28**

**ESPIPE = 29**

**EROFS = 30**

**EMLINK = 31**

**EPIPE = 32**

**EDOM = 33**

**ERANGE = 34**

**__init__**(*stdin=None*, *stdout=None*, *stderr=None*, *fd=None*, *sockets=None*, *socket_queue=None*, *argv=None*, *argc=None*, *environ=None*, *auxv=None*, *tls_modules=None*, *sigmask=None*, *pid=None*, *ppid=None*, *uid=None*, *gid=None*, *brk=None*)

**property closed_fds**

**set_brk**(*new_brk*)

**open**(*name*, *flags*, *preferred_fd=None*)

Open a symbolic file. Basically open(2).

**Parameters**

- **name** (*string or bytes*) – Path of the symbolic file, as a string or bytes.
- **flags** – File operation flags, a bitfield of constants from open(2), as an AST
- **preferred_fd** – Assign this fd if it's not already claimed.

**Returns**

The file descriptor number allocated (maps through posix.get_fd to a SimFileDescriptor) or -1 if the open fails.

`mode` from open(2) is unsupported at present.

**open_socket**(*ident*)

**get_fd**(*fd*, *create_file=True*)

Looks up the SimFileDescriptor associated with the given number (an AST). If the number is concrete and does not map to anything, return None. If the number is symbolic, constrain it to an open fd and create a new file for it. Set create_file to False if no write-access is planned (i.e. fd is read-only).

**get_concrete_fd**(*fd*, *create_file=True*)

Same behavior as get_fd(fd), only the result is a concrete integer fd (or -1) instead of a SimFileDescriptor.

**close**(*fd*)

Closes the given file descriptor (an AST). Returns whether the operation succeeded (a concrete boolean)

**fstat**(*fd*)

**fstat_with_result**(*sim_fd*)

**sigmask**(*sigsetsize=None*)

Gets the current sigmask. If it's blank, a new one is created (of sigsetsize).

**Parameters**
**sigsetsize** – the size (in *bytes* of the sigmask set)

**Returns**
the sigmask

**sigprocmask**(*how*, *new_mask*, *sigsetsize*, *valid_ptr=True*)

Updates the signal mask.

**Parameters**

- **how** – the "how" argument of sigprocmask (see manpage)
- **new_mask** – the mask modification to apply
- **sigsetsize** – the size (in *bytes* of the sigmask set)
- **valid_ptr** – is set if the new_mask was not NULL

**dump_file_by_path**(*path*, ***kwargs*)

Returns the concrete content for a file by path.

**Parameters**

- **path** – file path as string
- **kwargs** – passed to state.solver.eval

**Returns**
file contents as string

**dumps**(*fd*, ***kwargs*)

Returns the concrete content for a file descriptor.

BACKWARD COMPATIBILITY: if you ask for file descriptors 0 1 or 2, it will return the data from stdin, stdout, or stderr as a flat string.

**Parameters**
**fd** – A file descriptor.

**Returns**
The concrete content.

**Return type**
str

### 10.45.20 angr.state_plugins.preconstrainer

**class** angr.state_plugins.preconstrainer.**SimStatePreconstrainer**

Bases: *SimStatePlugin*

This state plugin manages the concept of preconstraining - adding constraints which you would like to remove later.

**Parameters**
**constrained_addrs** – SimActions for memory operations whose addresses should be constrained during crash analysis

**__init__**(*constrained_addrs=None*)

**preconstrain**(*value*, *variable*)

Add a preconstraint that `variable == value` to the state.

**Parameters**

- **value** – The concrete value. Can be a bitvector or a bytestring or an integer.
- **variable** – The BVS to preconstrain.

**preconstrain_file**(*content*, *simfile*, *set_length=False*)

Preconstrain the contents of a file.

**Parameters**

- **content** – The content to preconstrain the file to. Can be a bytestring or a list thereof.
- **simfile** – The actual simfile to preconstrain

**preconstrain_flag_page**(*magic_content*)

Preconstrain the data in the flag page.

**Parameters**
**magic_content** – The content of the magic page as a bytestring.

**remove_preconstraints**(*to_composite_solver=True*, *simplify=True*)

Remove the preconstraints from the state.

If you are using the zen plugin, this will also use that to filter the constraints.

**Parameters**

- **to_composite_solver** – Whether to convert the replacement solver to a composite solver. You probably want this if you're switching from tracing to symbolic analysis.
- **simplify** – Whether to simplify the resulting set of constraints.

**reconstrain**()

Split the solver. If any of the subsolvers time out after a short timeout (10 seconds), re-add the preconstraints associated with each of its variables. Hopefully these constraints still allow us to do meaningful things to the state.

### 10.45.21 angr.state_plugins.scratch

**class** angr.state_plugins.scratch.**SimStateScratch**

Bases: *SimStatePlugin*

Implements the scratch state plugin.

**__init__**(*scratch=None*)

**property ail_block_idx**

**property is_ail**

**property priv**

**push_priv**(*priv*)

**pop_priv**()

**set_tyenv**(*tyenv*)

**tmp_expr**(*tmp*)

Returns the Claripy expression of a VEX temp value.

**Parameters**

- **tmp** – the number of the tmp
- **simplify** – simplify the tmp before returning it

**Returns**
a Claripy expression of the tmp

**store_tmp**(*tmp*, *content*, *reg_deps=frozenset({})*, *tmp_deps=frozenset({})*, *deps=None*, ***kwargs*)

Stores a Claripy expression in a VEX temp value. If in symbolic mode, this involves adding a constraint for the tmp's symbolic variable.

**Parameters**

- **tmp** – the number of the tmp
- **content** – a Claripy expression of the content
- **reg_deps** – the register dependencies of the content
- **tmp_deps** – the temporary value dependencies of the content

**clear**()

### 10.45.22 angr.state_plugins.sim_action

**class** angr.state_plugins.sim_action.**SimAction**

Bases: *SimEvent*

A SimAction represents a semantic action that an analyzed program performs.

**TMP = 'tmp'**

**REG = 'reg'**

**MEM = 'mem'**

**__init__**(*state*, *region_type*)

Initializes the SimAction.

**Parameters**
**state** – the state that's the SimAction is taking place in.

**property all_objects**

**property is_symbolic**

**property tmp_deps**

**property reg_deps**

**copy**()

**downsize**()

Clears some low-level details (that take up memory) out of the SimAction.

class angr.state_plugins.sim_action.**SimActionExit**

Bases: *SimAction*

An Exit action represents a (possibly conditional) jump.

**CONDITIONAL = 'conditional'**

**DEFAULT = 'default'**

**property all_objects**

**property is_symbolic**

class angr.state_plugins.sim_action.**SimActionConstraint**

Bases: *SimAction*

A constraint action represents an extra constraint added during execution of a path.

**property all_objects**

**property is_symbolic**

class angr.state_plugins.sim_action.**SimActionOperation**

Bases: *SimAction*

An action representing an operation between variables and/or constants.

**property all_objects**

**property is_symbolic**

class angr.state_plugins.sim_action.**SimActionData**

Bases: *SimAction*

A Data action represents a read or a write from memory, registers or a file.

**READ = 'read'**

**WRITE = 'write'**

**OPERATE = 'operate'**

**property all_objects**

**property is_symbolic**

**property tmp_deps**

**property reg_deps**

**property storage**

### 10.45.23 angr.state_plugins.sim_action_object

angr.state_plugins.sim_action_object.**ast_preserving_op**(*f*, **args*)

angr.state_plugins.sim_action_object.**ast_stripping_decorator**(*f*)

class angr.state_plugins.sim_action_object.**SimActionObject**

Bases: object

A SimActionObject tracks an AST and its dependencies.

**__init__**(*ast*, *reg_deps=frozenset({})*, *tmp_deps=frozenset({})*, *deps=frozenset({})*, *state=None*)

**Parameters**

- **ast** (*claripy.ast.Base*)
- **reg_deps** (*frozenset[SimActionData | SimActionOperation]*)
- **tmp_deps** (*frozenset[SimActionData | SimActionOperation]*)
- **deps** (*frozenset*)
- **state** (*SimState | None*)

**ast: Base**

**reg_deps: frozenset[*SimActionData* | *SimActionOperation*]**

**tmp_deps: frozenset[*SimActionData* | *SimActionOperation*]**

**to_claripy**()

**Return type**
Base

**copy**()

**Return type**
*SimActionObject*

**is_leaf**()

**Return type**
bool

**property op: str**

**property args: tuple[ArgType, ...]**

**property length: int | None**

**property variables: frozenset[str]**

**property symbolic: bool**

**property annotations: tuple[Annotation, ...]**

**property depth: int**

**SDiv**(*other*)

**Return type**
*SimActionObject*

**SMod**(*other*)

**Return type**
*SimActionObject*

**union**(*other*)

**Return type**
*SimActionObject*

**intersection**(*other*)

**Return type**
*SimActionObject*

**widen**(*other*)

**Return type**
*SimActionObject*

**raw_to_bv**()

**Return type**
*SimActionObject*

**bv_to_fp**()

**Return type**
*SimActionObject*

### 10.45.24 angr.state_plugins.sim_event

**class** angr.state_plugins.sim_event.**SimEvent**

Bases: object

A SimEvent is a log entry for some notable event during symbolic execution. It logs the location it was generated (ins_addr, bbl_addr, stmt_idx, and sim_procedure) as well as arbitrary tags (objects).

You may also be interested in SimAction, which is a specialization of SimEvent for CPU events.

**__init__**(*state*, *event_type*, ***kwargs*)

angr.state_plugins.sim_event.**resource_event**(*state*, *exception*)

### 10.45.25 angr.state_plugins.solver

angr.state_plugins.solver.**timed_function**(*f*)

angr.state_plugins.solver.**enable_timing**()

angr.state_plugins.solver.**disable_timing**()

angr.state_plugins.solver.**error_converter**(*f*)

angr.state_plugins.solver.**concrete_path_bool**(*f*)

angr.state_plugins.solver.**concrete_path_not_bool**(*f*)

angr.state_plugins.solver.**concrete_path_scalar**(*f*)

angr.state_plugins.solver.**concrete_path_tuple**(*f*)

angr.state_plugins.solver.**concrete_path_list**(*f*)

**class** angr.state_plugins.solver.**SimSolver**

Bases: *SimStatePlugin*

This is the plugin you'll use to interact with symbolic variables, creating them and evaluating them. It should be available on a state as `state.solver`.

Any top-level variable of the claripy module can be accessed as a property of this object.

**__init__**(*solver=None*, *all_variables=None*, *temporal_tracked_variables=None*, *eternal_tracked_variables=None*)

**reload_solver**(*constraints=None*)

Reloads the solver. Useful when changing solver options.

**Parameters**

**constraints** (*list*) – A new list of constraints to use in the reloaded solver instead of the current one

**get_variables**(**keys*)

Iterate over all variables for which their tracking key is a prefix of the values provided.

Elements are a tuple, the first element is the full tracking key, the second is the symbol.

```
>>> list(s.solver.get_variables('mem'))
[(('mem', 0x1000), <BV64 mem_1000_4_64>), (('mem', 0x1008), <BV64 mem_1008_5_64>
↪)]
```

```
>>> list(s.solver.get_variables('file'))
[(('file', 1, 0), <BV8 file_1_0_6_8>), (('file', 1, 1), <BV8 file_1_1_7_8>),
    (('file', 2, 0), <BV8 file_2_0_8_8>)]
```

```
>>> list(s.solver.get_variables('file', 2))
[(('file', 2, 0), <BV8 file_2_0_8_8>)]
```

```
>>> list(s.solver.get_variables())
[(('mem', 0x1000), <BV64 mem_1000_4_64>), (('mem', 0x1008), <BV64 mem_1008_5_64>
↪),
    (('file', 1, 0), <BV8 file_1_0_6_8>), (('file', 1, 1), <BV8 file_1_1_7_8>),
    (('file', 2, 0), <BV8 file_2_0_8_8>)]
```

**register_variable**(*v*, *key*, *eternal=True*)

Register a value with the variable tracking system

**Parameters**

- **v** – The BVS to register
- **key** – A tuple to register the variable under

**Parma eternal**

Whether this is an eternal variable, default True. If False, an incrementing counter will be appended to the key.

**describe_variables**(*v*)

Given an AST, iterate over all the keys of all the BVS leaves in the tree which are registered.

**Unconstrained**(*name*, *bits*, *uninitialized=True*, *inspect=True*, *events=True*, *key=None*, *eternal=False*, *uc_alloc_depth=None*, ***kwargs*)

Creates an unconstrained symbol or a default concrete value (0), based on the state options.

**Parameters**

- **name** – The name of the symbol.
- **bits** – The size (in bits) of the symbol.
- **uninitialized** – Whether this value should be counted as an "uninitialized" value in the course of an analysis.
- **inspect** – Set to False to avoid firing SimInspect breakpoints
- **events** – Set to False to avoid generating a SimEvent for the occasion
- **key** – Set this to a tuple of increasingly specific identifiers (for example, `('mem', 0xffbeff00)` or `('file', 4, 0x20)` to cause it to be tracked, i.e. accessible through `solver.get_variables`.
- **eternal** – Set to True in conjunction with setting a key to cause all states with the same ancestry to retrieve the same symbol when trying to create the value. If False, a counter will be appended to the key.

**Returns**

an unconstrained symbol (or a concrete value of 0).

**BVS**(*name*, *size*, *min=None*, *max=None*, *stride=None*, *uninitialized=False*, *explicit_name=False*, *key=None*, *eternal=False*, *inspect=True*, *events=True*, ***kwargs*)

Creates a bit-vector symbol (i.e., a variable). Other keyword parameters are passed directly on to the constructor of claripy.ast.BV.

**Parameters**

- **name** – The name of the symbol.
- **size** – The size (in bits) of the bit-vector.
- **min** – The minimum value of the symbol. Note that this **only** work when using VSA.
- **max** – The maximum value of the symbol. Note that this **only** work when using VSA.
- **stride** – The stride of the symbol. Note that this **only** work when using VSA.
- **uninitialized** – Whether this value should be counted as an "uninitialized" value in the course of an analysis.
- **explicit_name** – Set to True to prevent an identifier from appended to the name to ensure uniqueness.
- **key** – Set this to a tuple of increasingly specific identifiers (for example, `('mem', 0xffbeff00)` or `('file', 4, 0x20)` to cause it to be tracked, i.e. accessible through `solver.get_variables`.
- **eternal** – Set to True in conjunction with setting a key to cause all states with the same ancestry to retrieve the same symbol when trying to create the value. If False, a counter will be appended to the key.
- **inspect** – Set to False to avoid firing SimInspect breakpoints
- **events** – Set to False to avoid generating a SimEvent for the occasion

**Returns**

A BV object representing this symbol.

**downsize**()

Frees memory associated with the constraint solver by clearing all of its internal caches.

**property constraints**

Returns the constraints of the state stored by the solver.

**eval_to_ast**(*e*, *n*, *extra_constraints=()*, *exact=None*)

Evaluate an expression, using the solver if necessary. Returns AST objects.

**Parameters**

- **e** – the expression
- **n** – the number of desired solutions
- **extra_constraints** – extra constraints to apply to the solver
- **exact** – if False, returns approximate solutions

**Returns**
a tuple of the solutions, in the form of claripy AST nodes

**Return type**
tuple

**max**(*e*, *extra_constraints=()*, *exact=None*, *signed=False*)

Return the maximum value of expression *e*.

:param e : expression (an AST) to evaluate :type extra_constraints: :param extra_constraints: extra constraints (as ASTs) to add to the solver for this solve :param exact : if False, return approximate solutions. :param signed : Whether the expression should be treated as a signed value. :return: the maximum possible value of e (backend object)

**min**(*e*, *extra_constraints=()*, *exact=None*, *signed=False*)

Return the minimum value of expression *e*.

:param e : expression (an AST) to evaluate :type extra_constraints: :param extra_constraints: extra constraints (as ASTs) to add to the solver for this solve :param exact : if False, return approximate solutions. :param signed : Whether the expression should be treated as a signed value. :return: the minimum possible value of e (backend object)

**solution**(*e*, *v*, *extra_constraints=()*, *exact=None*)

Return True if *v* is a solution of *expr* with the extra constraints, False otherwise.

**Parameters**

- **e** – An expression (an AST) to evaluate
- **v** – The proposed solution (an AST)
- **extra_constraints** – Extra constraints (as ASTs) to add to the solver for this solve.
- **exact** – If False, return approximate solutions.

**Returns**
True if *v* is a solution of *expr*, False otherwise

**is_true**(*e*, *extra_constraints=()*, *exact=None*)

If the expression provided is absolutely, definitely a true boolean, return True. Note that returning False doesn't necessarily mean that the expression can be false, just that we couldn't figure that out easily.

**Parameters**

- **e** – An expression (an AST) to evaluate

- **extra_constraints** – Extra constraints (as ASTs) to add to the solver for this solve.
- **exact** – If False, return approximate solutions.

**Returns**
True if *v* is definitely true, False otherwise

**is_false**(*e*, *extra_constraints=()*, *exact=None*)

If the expression provided is absolutely, definitely a false boolean, return True. Note that returning False doesn't necessarily mean that the expression can be true, just that we couldn't figure that out easily.

**Parameters**

- **e** – An expression (an AST) to evaluate
- **extra_constraints** – Extra constraints (as ASTs) to add to the solver for this solve.
- **exact** – If False, return approximate solutions.

**Returns**
True if *v* is definitely false, False otherwise

**unsat_core**(*extra_constraints=()*)

This function returns the unsat core from the backend solver.

**Parameters**
**extra_constraints** – Extra constraints (as ASTs) to add to the solver for this solve.

**Returns**
The unsat core.

**satisfiable**(*extra_constraints=()*, *exact=None*)

This function does a constraint check and checks if the solver is in a sat state.

**Parameters**

- **extra_constraints** – Extra constraints (as ASTs) to add to s for this solve
- **exact** – If False, return approximate solutions.

**Returns**
True if sat, otherwise false

**add**(**constraints*)

Add some constraints to the solver.

**Parameters**
**constraints** – Pass any constraints that you want to add (ASTs) as varargs.

**CastType = ~CastType**

**eval_upto**(*e*, *n*, *cast_to=None*, ***kwargs*)

Evaluate an expression, using the solver if necessary. Returns primitives as specified by the *cast_to* parameter. Only certain primitives are supported, check the implementation of *_cast_to* to see which ones.

**Overloads**

- **e** (BV), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[int]
- **e** (BV), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (Bool), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[bool]
- **e** (Bool), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (FP), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[float]

- **e** (FP), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (String | str), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[str]
- **e** (), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[Any]
- **e** (), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]

**Parameters**

- **e** – the expression
- **n** – the number of desired solutions
- **extra_constraints** – extra constraints to apply to the solver
- **exact** – if False, returns approximate solutions
- **cast_to** – desired type of resulting values

**Returns**
a tuple of the solutions, in the form of Python primitives

**Return type**
tuple

**eval**(*e*, *cast_to=None*, ***kwargs*)

Evaluate an expression to get any possible solution. The desired output types can be specified using the *cast_to* parameter. *extra_constraints* can be used to specify additional constraints the returned values must satisfy.

**Overloads**

- **e** (BV), **cast_to** (None) = ..., ****kwargs** → int
- **e** (BV), **cast_to** (type[CastType]), ****kwargs** → CastType
- **e** (Bool), **cast_to** (None) = ..., ****kwargs** → bool
- **e** (Bool), **cast_to** (type[CastType]), ****kwargs** → CastType
- **e** (FP), **cast_to** (None) = ..., ****kwargs** → float
- **e** (FP), **cast_to** (type[CastType]), ****kwargs** → CastType
- **e** (String | str), **cast_to** (None) = ..., ****kwargs** → str
- **e** (), **cast_to** (None) = ..., ****kwargs** →
- **e** (), **cast_to** (type[CastType]), ****kwargs** → CastType

**Parameters**

- **e** – the expression to get a solution for
- **kwargs** – Any additional kwargs will be passed down to *eval_upto*
- **cast_to** – desired type of resulting values

**Raises**
***SimUnsatError*** – if no solution could be found satisfying the given constraints

**Returns**

**eval_one**(*e*, *cast_to=None*, ***kwargs*)

Evaluate an expression to get the only possible solution. Errors if either no or more than one solution is returned. A kwarg parameter *default* can be specified to be returned instead of failure!

**Overloads**

- **e** (BV), **cast_to** (None) = ..., ****kwargs** → int
- **e** (BV), **cast_to** (type[CastType]), ****kwargs** → CastType
- **e** (Bool), **cast_to** (None) = ..., ****kwargs** → bool
- **e** (Bool), **cast_to** (type[CastType]), ****kwargs** → CastType
- **e** (FP), **cast_to** (None) = ..., ****kwargs** → float
- **e** (FP), **cast_to** (type[CastType]), ****kwargs** → CastType
- **e** (String | str), **cast_to** (None) = ..., ****kwargs** → str
- **e** (), **cast_to** (None) = ..., ****kwargs** →
- **e** (), **cast_to** (type[CastType]), ****kwargs** → CastType

**Parameters**

- **e** – the expression to get a solution for
- **cast_to** – desired type of resulting values
- **default** – A value can be passed as a kwarg here. It will be returned in case of failure.
- **kwargs** – Any additional kwargs will be passed down to *eval_upto*

**Raises**

- ***SimUnsatError*** – if no solution could be found satisfying the given constraints
- ***SimValueError*** – if more than one solution was found to satisfy the given constraints

**Returns**

The value for *e*

**eval_atmost**(*e*, *n*, *cast_to=None*, ***kwargs*)

Evaluate an expression to get at most *n* possible solutions. Errors if either none or more than *n* solutions are returned.

**Overloads**

- **e** (BV), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[int]
- **e** (BV), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (Bool), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[bool]
- **e** (Bool), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (FP), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[float]
- **e** (FP), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (String | str), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[str]
- **e** (), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[Any]
- **e** (), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]

**Parameters**

- **e** – the expression to get a solution for
- **n** – the inclusive upper limit on the number of solutions
- **cast_to** – desired type of resulting values

- **kwargs** – Any additional kwargs will be passed down to *eval_upto*

**Raises**

- ***SimUnsatError*** – if no solution could be found satisfying the given constraints
- ***SimValueError*** – if more than *n* solutions were found to satisfy the given constraints

**Returns**

The solutions for *e*

**eval_atleast**(*e*, *n*, *cast_to=None*, ***kwargs*)

Evaluate an expression to get at least *n* possible solutions. Errors if less than *n* solutions were found.

**Overloads**

- **e** (BV), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[int]
- **e** (BV), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (Bool), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[bool]
- **e** (Bool), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (FP), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[float]
- **e** (FP), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (String | str), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[str]
- **e** (), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[Any]
- **e** (), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]

**Parameters**

- **e** – the expression to get a solution for
- **n** – the inclusive lower limit on the number of solutions
- **cast_to** – desired type of resulting values
- **kwargs** – Any additional kwargs will be passed down to *eval_upto*

**Raises**

- ***SimUnsatError*** – if no solution could be found satisfying the given constraints
- ***SimValueError*** – if less than *n* solutions were found to satisfy the given constraints

**Returns**

The solutions for *e*

**eval_exact**(*e*, *n*, *cast_to=None*, ***kwargs*)

Evaluate an expression to get exactly the *n* possible solutions. Errors if any number of solutions other than *n* was found to exist.

**Overloads**

- **e** (BV), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[int]
- **e** (BV), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (Bool), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[bool]
- **e** (Bool), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (FP), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[float]

- **e** (FP), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]
- **e** (String | str), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[str]
- **e** (), **n** (int), **cast_to** (None) = ..., ****kwargs** → list[Any]
- **e** (), **n** (int), **cast_to** (type[CastType]), ****kwargs** → list[CastType]

**Parameters**

- **e** – the expression to get a solution for
- **n** – the inclusive lower limit on the number of solutions
- **cast_to** – desired type of resulting values
- **kwargs** – Any additional kwargs will be passed down to *eval_upto*

**Raises**

- ***SimUnsatError*** – if no solution could be found satisfying the given constraints
- ***SimValueError*** – if any number of solutions other than *n* were found to satisfy the given constraints

**Returns**

The solutions for *e*

**min_int**(*e*, *extra_constraints=()*, *exact=None*, *signed=False*)

Return the minimum value of expression *e*.

:param e : expression (an AST) to evaluate :type extra_constraints: :param extra_constraints: extra constraints (as ASTs) to add to the solver for this solve :param exact : if False, return approximate solutions. :param signed : Whether the expression should be treated as a signed value. :return: the minimum possible value of e (backend object)

**max_int**(*e*, *extra_constraints=()*, *exact=None*, *signed=False*)

Return the maximum value of expression *e*.

:param e : expression (an AST) to evaluate :type extra_constraints: :param extra_constraints: extra constraints (as ASTs) to add to the solver for this solve :param exact : if False, return approximate solutions. :param signed : Whether the expression should be treated as a signed value. :return: the maximum possible value of e (backend object)

**unique**(*e*, ***kwargs*)

Returns True if the expression *e* has only one solution by querying the constraint solver. It does also add that unique solution to the solver's constraints.

**symbolic**(*e*)

Returns True if the expression *e* is symbolic.

**single_valued**(*e*)

Returns True whether *e* is a concrete value or is a value set with only 1 possible value. This differs from *unique* in that this *does* not query the constraint solver.

**simplify**(*e=None*)

Simplifies *e*. If *e* is None, simplifies the constraints of this state.

**variables**(*e*)

Returns the symbolic variables present in the AST of *e*.

### 10.45.26 angr.state_plugins.symbolizer

**class** angr.state_plugins.symbolizer.**SimSymbolizer**

Bases: *SimStatePlugin*

The symbolizer state plugin ensures that pointers that are stored in memory are symbolic. This allows for the tracking of and reasoning over these pointers (for example, to reason about memory disclosure).

**__init__**()

**set_symbolization_for_all_pages**()

Sets the symbolizer to symbolize pointers to all pages as they are written to memory..

**set_symbolized_target_range**(*base*, *length*)

All pointers to the target range will be symbolized as they are written to memory.

Due to optimizations, the _pages_ containing this range will be set as symbolization targets, not just the range itself.

**resymbolize**()

Re-symbolizes all pointers in memory. This can be called to symbolize any pointers to target regions that were written (and not mangled beyond recognition) before symbolization was set.

### 10.45.27 angr.state_plugins.trace_additions

This file contains objects to track additional information during a trace or modify symbolic variables during a trace.

The ChallRespInfo plugin tracks variables in stdin and stdout to enable handling of challenge response It handles atoi/int2str in a special manner since path constraints will usually prevent their values from being modified

The Zen plugin simplifies expressions created from variables in the flag page (losing some accuracy) to avoid situations where they become to complex for z3, but the actual equation doesn't matter much. This can happen in challenge response if all of the values in the flag page are multiplied together before being printed.

**class** angr.state_plugins.trace_additions.**FormatInfo**

### 10.45.28 angr.state_plugins.uc_manager

class angr.state_plugins.uc_manager.**SimUCManager**

Bases: *SimStatePlugin*

**__init__**(*man=None*)

**assign**(*dst_addr_ast*)

Assign a new region for under-constrained symbolic execution.

**Parameters**
**dst_addr_ast** – the symbolic AST which address of the new allocated region will be assigned to.

**Returns**
as ast of memory address that points to a new region

**get_alloc_depth**(*addr*)

**Return type**
int | None

**Parameters**
**addr** (*int | Base*)

**set_alloc_depth**(*addr*, *depth*)

**Parameters**

- **addr** (*Base*)
- **depth** (*int*)

**is_bounded**(*ast*)

Test whether an AST is bounded by any existing constraint in the related solver.

**Parameters**
**ast** – an claripy.AST object

**Returns**
True if there is at least one related constraint, False otherwise

### 10.45.30 angr.state_plugins.view

**class** angr.state_plugins.view.**SimRegNameView**

Bases: *SimStatePlugin*

**get**(*reg_name*)

**class** angr.state_plugins.view.**SimMemView**

Bases: *SimStatePlugin*

This is a convenient interface with which you can access a program's memory.

The interface works like this:

- You first use [array index notation] to specify the address you'd like to load from
- If at that address is a pointer, you may access the `deref` property to return a SimMemView at the address present in memory.

- You then specify a type for the data by simply accessing a property of that name. For a list of supported types, look at `state.mem.types`.
- You can then *refine* the type. Any type may support any refinement it likes. Right now the only refinements supported are that you may access any member of a struct by its member name, and you may index into a string or array to access that element.
- If the address you specified initially points to an array of that type, you can say *.array(n)* to view the data as an array of n elements.
- Finally, extract the structured data with `.resolved` or `.concrete`. `.resolved` will return bitvector values, while `.concrete` will return integer, string, array, etc values, whatever best represents the data.
- Alternately, you may store a value to memory, by assigning to the chain of properties that you've constructed. Note that because of the way python works, `x = s.mem[...].prop; x = val` will NOT work, you must say `s.mem[...].prop = val`.

For example:

```
>>> s.mem[0x601048].long
<long (64 bits) <BV64 0x4008d0> at 0x601048>
>>> s.mem[0x601048].long.resolved
<BV64 0x4008d0>
>>> s.mem[0x601048].deref
<<untyped> <unresolvable> at 0x4008d0>
>>> s.mem[0x601048].deref.string.concrete
'SOSNEAKY'
```

**state:** *SimState*[Any, Any] = None

**struct:** *StructMode*

**with_type**(*sim_type*)

Returns a copy of the SimMemView with a type.

**Parameters**
**sim_type** (*SimType*) – The new type.

**Return type**
*SimMemView*

**Returns**
The typed SimMemView copy.

**property resolvable**

**property resolved**

**property concrete**

**property deref:** *SimMemView*

**array**(*n*)

**Return type**
*SimMemView*

**member**(*member_name*)

If self is a struct and member_name is a member of the struct, return that member element. Otherwise raise an exception.

**Return type**
*SimMemView*

**Parameters**
**member_name** (*str*)

**store**(*value*)

**class** angr.state_plugins.view.**StructMode**

Bases: object

**__init__**(*view*)

## 10.46 angr.storage

**class** angr.storage.**DefaultMemory**

Bases: *HexDumperMixin*, *SmartFindMixin*, *UnwrapperMixin*, *NameResolutionMixin*, *DataNormalizationMixin*, *SimplificationMixin*, *InspectMixin*, *ActionsMixinHigh*, *UnderconstrainedMixin*, *SizeConcretizationMixin*, *SizeNormalizationMixin*, *AddressConcretizationMixin*, *ActionsMixinLow*, *ConditionalMixin*, *ConvenientMappingsMixin*, *DirtyAddrsMixin*, *StackAllocationMixin*, *ClemoryBackerMixin*, *DictBackerMixin*, *PrivilegedPagingMixin*, *UltraPagesMixin*, *DefaultFillerMixin*, *SymbolicMergerMixin*, *PagedMemoryMixin*

class angr.storage.SimFile

Bases: *SimFileBase*, *DefaultMemory*

The normal SimFile is meant to model files on disk. It subclasses SimSymbolicMemory so loads and stores to/from it are very simple.

**Parameters**

- **name** – The name of the file
- **content** – Optional initial content for the file as a string or bitvector
- **size** – Optional size of the file. If content is not specified, it defaults to zero
- **has_end** – Whether the size boundary is treated as the end of the file or a frontier at which new content will be generated. If unspecified, will pick its value based on options.FILES_HAVE_EOF. Another caveat is that if the size is also unspecified this value will default to False.
- **seekable** – Optional bool indicating whether seek operations on this file should succeed, default True.
- **writable** – Whether writing to this file is allowed
- **concrete** – Whether or not this file contains mostly concrete data. Will be used by some SimProcedures to choose how to handle variable-length operations like fgets.

**Variables**

**has_end** – Whether this file has an EOF

__init__(*name=None*, *content=None*, *size=None*, *has_end=None*, *seekable=True*, *writable=True*, *ident=None*, *concrete=None*, ***kwargs*)

property category

reg, mem, or file.

**Type**

Return the category of this SimMemory instance. It can be one of the three following categories

property size

The number of data bytes stored by the file at present. May be a symbolic value.

concretize(***kwargs*)

Return a concretization of the contents of the file, as a flat bytestring.

class angr.storage.SimMemoryObject

Bases: object

A SimMemoryObject is a reference to a byte or several bytes in a specific object in memory. It should be used only by the bottom layer of memory.

__init__(*obj*, *base*, *endness*, *length=None*, *byte_width=8*)

**class** angr.storage.file.**SimFileBase**

Bases: *SimStatePlugin*

SimFiles are the storage mechanisms used by SimFileDescriptors.

Different types of SimFiles can have drastically different interfaces, and as a result there's not much that can be specified on this base class. All the read and write methods take a `pos` argument, which may have different semantics per-class. `0` will always be a valid position to use, though, and the next position you should use is part of the return tuple.

Some simfiles are "streams", meaning that the position that reads come from is determined not by the position you pass in (it will in fact be ignored), but by an internal variable. This is stored as `.pos` if you care to read it. Don't write to it. The same lack-of-semantics applies to this field as well.

**Variables**

- **name** – The name of the file. Purely for cosmetic purposes
- **ident** – The identifier of the file, typically autogenerated from the name and a nonce. Purely for cosmetic purposes, but does appear in symbolic values autogenerated in the file.
- **seekable** – Bool indicating whether seek operations on this file should succeed. If this is True, then `pos` must be a number of bytes from the start of the file.
- **writable** – Bool indicating whether writing to this file is allowed.
- **pos** – If the file is a stream, this will be the current position. Otherwise, None.
- **concrete** – Whether or not this file contains mostly concrete data. Will be used by some SimProcedures to choose how to handle variable-length operations like fgets.
- **file_exists** – Set to False, if file does not exists, set to a claripy Bool if unknown, default True.

**seekable = False**

**pos = None**

**__init__**(*name=None*, *writable=True*, *ident=None*, *concrete=False*, *file_exists=True*, ***kwargs*)

**static make_ident**(*name*)

**concretize**(***kwargs*)

Return a concretization of the contents of the file. The type of the return value of this method will vary depending on which kind of SimFile you're using.

**read**(*pos*, *size*, ***kwargs*)

Read some data from the file.

**Parameters**

- **pos** – The offset in the file to read from.
- **size** – The size to read. May be symbolic.

**Returns**

A tuple of the data read (a bitvector of the length that is the maximum length of the read), the actual size of the read, and the new file position pointer.

**write**(*pos*, *data*, *size=None*, ***kwargs*)

Write some data to the file.

**Parameters**

- **pos** – The offset in the file to write to. May be ignored if the file is a stream or device.
- **data** – The data to write as a bitvector
- **size** – The optional size of the data to write. If not provided will default to the length of the data. Must be constrained to less than or equal to the size of the data.

**Returns**

The new file position pointer.

**property size**

The number of data bytes stored by the file at present. May be a symbolic value.

**class** angr.storage.file.**SimFile**

Bases: *SimFileBase*, *DefaultMemory*

The normal SimFile is meant to model files on disk. It subclasses SimSymbolicMemory so loads and stores to/from it are very simple.

**Parameters**

- **name** – The name of the file
- **content** – Optional initial content for the file as a string or bitvector
- **size** – Optional size of the file. If content is not specified, it defaults to zero
- **has_end** – Whether the size boundary is treated as the end of the file or a frontier at which new content will be generated. If unspecified, will pick its value based on options.FILES_HAVE_EOF. Another caveat is that if the size is also unspecified this value will default to False.
- **seekable** – Optional bool indicating whether seek operations on this file should succeed, default True.
- **writable** – Whether writing to this file is allowed
- **concrete** – Whether or not this file contains mostly concrete data. Will be used by some SimProcedures to choose how to handle variable-length operations like fgets.

**Variables**

**has_end** – Whether this file has an EOF

__init__(*name=None*, *content=None*, *size=None*, *has_end=None*, *seekable=True*, *writable=True*, *ident=None*, *concrete=None*, ***kwargs*)

property category

reg, mem, or file.

**Type**
Return the category of this SimMemory instance. It can be one of the three following categories

property size

The number of data bytes stored by the file at present. May be a symbolic value.

concretize(***kwargs*)

Return a concretization of the contents of the file, as a flat bytestring.

class angr.storage.file.SimFileStream

Bases: *SimFile*

A specialized SimFile that uses a flat memory backing, but functions as a stream, tracking its position internally.

The pos argument to the read and write methods will be ignored, and will return None. Instead, there is an attribute pos on the file itself, which will give you what you want.

**Parameters**

- **name** – The name of the file, for cosmetic purposes
- **pos** – The initial position of the file, default zero
- **kwargs** – Any other keyword arguments will go on to the SimFile constructor.

**Variables**
**pos** – The current position in the file.

__init__(*name=None*, *content=None*, *pos=0*, ***kwargs*)

class angr.storage.file.SimPackets

Bases: *SimFileBase*

The SimPackets is meant to model inputs whose content is delivered a series of asynchronous chunks. The data is stored as a list of read or write results. For symbolic sizes, state.libc.max_packet_size will be respected. If the SHORT_READS option is enabled, reads will return a symbolic size constrained to be less than or equal to the requested size.

A SimPackets cannot be used for both reading and writing - for socket objects that can be both read and written to you should use a file descriptor to multiplex the read and write operations into two separate file storage mechanisms.

**Parameters**

- **name** – The name of the file, for cosmetic purposes
- **write_mode** – Whether this file is opened in read or write mode. If this is unspecified it will be autodetected.
- **content** – Some initial content to use for the file. Can be a list of bytestrings or a list of tuples of content ASTs and size ASTs.

**Variables**

- **write_mode** – See the eponymous parameter
- **content** – A list of packets, as tuples of content ASTs and size ASTs.

**__init__**(*name*, *write_mode=None*, *content=None*, *writable=True*, *ident=None*, ***kwargs*)

**property size**

The number of data bytes stored by the file at present. May be a symbolic value.

**concretize**(***kwargs*)

Returns a list of the packets read or written as bytestrings.

**read**(*pos*, *size*, ***kwargs*)

Read a packet from the stream.

**Parameters**

- **pos** (*int*) – The packet number to read from the sequence of the stream. May be None to append to the stream.
- **size** – The size to read. May be symbolic.
- **short_reads** – Whether to replace the size with a symbolic value constrained to less than or equal to the original size. If unspecified, will be chosen based on the state option.

**Returns**

A tuple of the data read (a bitvector of the length that is the maximum length of the read) and the actual size of the read.

**write**(*pos*, *data*, *size=None*, *events=True*, ***kwargs*)

Write a packet to the stream.

**Parameters**

- **pos** (*int*) – The packet number to write in the sequence of the stream. May be None to append to the stream.
- **data** – The data to write, as a string or bitvector.
- **size** – The optional size to write. May be symbolic; must be constrained to at most the size of data.

**Returns**

The next packet to use after this

**class** angr.storage.file.**SimPacketsStream**

Bases: *SimPackets*

A specialized SimPackets that tracks its position internally.

The pos argument to the read and write methods will be ignored, and will return None. Instead, there is an attribute `pos` on the file itself, which will give you what you want.

**Parameters**

- **name** – The name of the file, for cosmetic purposes
- **pos** – The initial position of the file, default zero
- **kwargs** – Any other keyword arguments will go on to the SimPackets constructor.

**Variables**

**pos** – The current position in the file.

**__init__**(*name*, *pos=0*, ***kwargs*)

**class** angr.storage.file.**SimFileDescriptorBase**

Bases: *SimStatePlugin*

The base class for implementations of POSIX file descriptors.

All file descriptors should respect the CONCRETIZE_SYMBOLIC_{READ,WRITE}_SIZES state options.

**read**(*pos*, *size*, ***kwargs*)

Reads some data from the file, storing it into memory.

**Parameters**

- **pos** – The address to read data from file
- **size** – The requested length of the read

**Returns**
The real length of the read

**write**(*pos*, *size*, ***kwargs*)

Writes some data, loaded from the state, into the file.

**Parameters**

- **pos** – The address to read the data to write from in memory
- **size** – The requested size of the write

**Returns**
The real length of the write

**read_data**(*size*, ***kwargs*)

Reads some data from the file, returning the data.

**Parameters**
**size** – The requested length of the read

**Returns**
A tuple of the data read and the real length of the read

**write_data**(*data*, *size=None*, ***kwargs*)

Write some data, provided as an argument into the file.

**Parameters**

- **data** – A bitvector to write into the file
- **size** – The requested size of the write (may be symbolic)

**Returns**
The real length of the write

**seek**(*offset*, *whence='start'*)

Seek the file descriptor to a different position in the file.

**Parameters**

- **offset** – The offset to seek to, interpreted according to whence
- **whence** – What the offset is relative to; one of the strings “start”, “current”, or “end”

**Returns**
A symbolic boolean describing whether the seek succeeded or not

**tell**()

Return the current position, or None if the concept doesn't make sense for the given file.

**eof**()

Return the EOF status. May be a symbolic boolean.

**size**()

Return the size of the data stored in the file in bytes, or None if the concept doesn't make sense for the given file.

**property read_storage**

Return the SimFile backing reads from this fd

**property write_storage**

Return the SimFile backing writes to this fd

**property read_pos**

Return the current position of the read file pointer.

If the underlying read file is a stream, this will return the position of the stream. Otherwise, will return the position of the file descriptor in the file.

**property write_pos**

Return the current position of the read file pointer.

If the underlying read file is a stream, this will return the position of the stream. Otherwise, will return the position of the file descriptor in the file.

**concretize**(***kwargs*)

Return a concretizeation of the data in the underlying file. Has different return types to represent different data structures on a per-class basis.

Any arguments passed to this will be passed onto state.solver.eval.

**property file_exists**

This should be True in most cases. Only if we opened an fd of unknown existence, ALL_FILES_EXIST is False and ANY_FILE_MIGHT_EXIST is True, this is a symbolic boolean.

**class** angr.storage.file.**SimFileDescriptor**

Bases: *SimFileDescriptorBase*

A simple file descriptor forwarding reads and writes to a SimFile. Contains information about the current opened state of the file, such as the flags or (if relevant) the current position.

**Variables**

- **file** – The SimFile described to by this descriptor
- **flags** – The mode that the file descriptor was opened with, a bitfield of flags

**__init__**(*simfile*, *flags=0*)

**concretize**(***kwargs*)

Return a concretization of the underlying file. Returns whatever format is preferred by the file.

**property file_exists**

This should be True in most cases. Only if we opened an fd of unknown existence, ALL_FILES_EXIST is False and ANY_FILE_MIGHT_EXIST is True, this is a symbolic boolean.

**property read_storage**

Return the SimFile backing reads from this fd

**property write_storage**

Return the SimFile backing writes to this fd

**property read_pos**

Return the current position of the read file pointer.

If the underlying read file is a stream, this will return the position of the stream. Otherwise, will return the position of the file descriptor in the file.

**property write_pos**

Return the current position of the read file pointer.

If the underlying read file is a stream, this will return the position of the stream. Otherwise, will return the position of the file descriptor in the file.

**class** angr.storage.file.**SimFileDescriptorDuplex**

Bases: *SimFileDescriptorBase*

A file descriptor that refers to two file storage mechanisms, one to read from and one to write to. As a result, operations like seek, eof, etc no longer make sense.

**Parameters**

- **read_file** – The SimFile to read from
- **write_file** – The SimFile to write to

**__init__**(*read_file*, *write_file*)

**concretize**(***kwargs*)

Return a concretization of the underlying files, as a tuple of (read file, write file).

**property read_storage**

Return the SimFile backing reads from this fd

**property write_storage**

Return the SimFile backing writes to this fd

**property read_pos**

Return the current position of the read file pointer.

If the underlying read file is a stream, this will return the position of the stream. Otherwise, will return the position of the file descriptor in the file.

**property write_pos**

Return the current position of the read file pointer.

If the underlying read file is a stream, this will return the position of the stream. Otherwise, will return the position of the file descriptor in the file.

**class** angr.storage.file.**SimPacketsSlots**

Bases: *SimFileBase*

SimPacketsSlots is the new SimDialogue, if you've ever seen that before.

The idea is that in some cases, the only thing you really care about is getting the lengths of reads right, and some of them should be short reads, and some of them should be truncated. You provide to this class a list of read lengths, and it figures out the length of each read, and delivers some content.

This class will NOT respect the position argument you pass it - this storage is not stateless.

**seekable = False**

**__init__**(*name*, *read_sizes*, *ident=None*, ***kwargs*)

**property size**

The number of data bytes stored by the file at present. May be a symbolic value.

### 10.46.2 angr.storage.memory_mixins

**class** angr.storage.memory_mixins.**AbstractMemory**

Bases: *UnwrapperMixin*, *NameResolutionMixin*, *DataNormalizationMixin*, *SimplificationMixin*, *InspectMixin*, *ActionsMixinHigh*, *UnderconstrainedMixin*, *SizeConcretizationMixin*, *SizeNormalizationMixin*, *ActionsMixinLow*, *ConditionalMixin*, *RegionedAddressConcretizationMixin*, *RegionedMemoryMixin*

**class** angr.storage.memory_mixins.**AbstractMergerMixin**

Bases: *MemoryMixin*

AbstractMergerMixin handles merging initialized values.

**MERGE_WHOLE_OBJECTS = True**

**class** angr.storage.memory_mixins.**ActionsMixinHigh**

Bases: *MemoryMixin*

**load**(*addr*, *size=None*, ***, *condition=None*, *fallback=None*, *disable_actions=False*, *action=None*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, ***, *disable_actions=False*, *action=None*, *condition=None*, ***kwargs*)

**class** angr.storage.memory_mixins.**ActionsMixinLow**

Bases: *MemoryMixin*

**load**(*addr*, *size=None*, ***, *action=None*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, ***, *action=None*, ***kwargs*)

**Parameters**
**action** (SimActionData | *None*)

**class** angr.storage.memory_mixins.**AddressConcretizationMixin**

Bases: *MemoryMixin*

The address concretization mixin allows symbolic reads and writes to be handled sanely by dispatching them as a number of conditional concrete reads/writes. It provides a "concretization strategies" interface allowing the process of serializing symbolic addresses into concrete ones to be specified.

**__init__**(*read_strategies=None*, *write_strategies=None*, ***kwargs*)

**concretize_write_addr**(*addr*, *strategies=None*, *condition=None*)

Concretizes an address meant for writing.

**Parameters**

- **addr** – An expression for the address.
- **strategies** – A list of concretization strategies (to override the default).
- **condition** – Any extra constraints that should be observed when determining address satisfiability

**Returns**
A list of concrete addresses.

**concretize_read_addr**(*addr*, *strategies=None*, *condition=None*)

Concretizes an address meant for reading.

**Parameters**

- **addr** – An expression for the address.
- **strategies** – A list of concretization strategies (to override the default).

**Returns**
A list of concrete addresses.

**load**(*addr*, *size=None*, *, *condition=None*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, *, *condition=None*, ***kwargs*)

**permissions**(*addr*, *permissions=None*, ***kwargs*)

**map_region**(*addr*, *length*, *permissions*, ***kwargs*)

**unmap_region**(*addr*, *length*, ***kwargs*)

**class** angr.storage.memory_mixins.**ClemoryBackerMixin**

Bases: *PagedMemoryMixin*

**__init__**(*cle_memory_backer=None*, ***kwargs*)

**Parameters**
**cle_memory_backer** (*Loader | Clemory | None*)

**class** angr.storage.memory_mixins.**ConditionalMixin**

Bases: *MemoryMixin*

**load**(*addr*, *size=None*, *, *condition=None*, *fallback=None*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, *, *condition=None*, ***kwargs*)

**class** angr.storage.memory_mixins.**ConvenientMappingsMixin**

Bases: *MemoryMixin*

Implements mappings between names and hashes of symbolic variables and these variables themselves.

**__init__**(***kwargs*)

**store**(*addr*, *data*, *size=None*, ***kwargs*)

**get_symbolic_addrs**()

**addrs_for_name**(*n*)

Returns addresses that contain expressions that contain a variable named *n*.

**addrs_for_hash**(*h*)

Returns addresses that contain expressions that contain a variable with the hash of *h*.

**replace_all**(*old*, *new*)

Replaces all instances of expression *old* with expression *new*.

**Parameters**

- **old** (BV) – A claripy expression. Must contain at least one named variable (to make it possible to use the name index for speedup).
- **new** (BV) – The new variable to replace it with.

**class** angr.storage.memory_mixins.**CooperationBase**

Bases: Generic[T]

Any given subclass of this class which is not a subclass of MemoryMixin should have the property that any subclass it which *is* a subclass of MemoryMixin should all work with the same datatypes

**class** angr.storage.memory_mixins.**DataNormalizationMixin**

Bases: *MemoryMixin*

Normalizes the data field for a store and the fallback field for a load to be BVs.

**store**(*addr*, *data*, *size=None*, ***kwargs*)

**load**(*addr*, *size=None*, ***, *fallback=None*, ***kwargs*)

**class** angr.storage.memory_mixins.**DefaultFillerMixin**

Bases: *MemoryMixin*

**class** angr.storage.memory_mixins.**DefaultListPagesMemory**

Bases: *HexDumperMixin*, *SmartFindMixin*, *UnwrapperMixin*, *NameResolutionMixin*, *DataNormalizationMixin*, *SimplificationMixin*, *ActionsMixinHigh*, *UnderconstrainedMixin*, *SizeConcretizationMixin*, *SizeNormalizationMixin*, *InspectMixin*, *AddressConcretizationMixin*, *ActionsMixinLow*, *ConditionalMixin*, *ConvenientMappingsMixin*, *DirtyAddrsMixin*, *StackAllocationMixin*, *ClemoryBackerMixin*, *DictBackerMixin*, *PrivilegedPagingMixin*, *ListPagesMixin*, *DefaultFillerMixin*, *SymbolicMergerMixin*, *PagedMemoryMixin*

**class** angr.storage.memory_mixins.**DefaultMemory**

Bases: *HexDumperMixin*, *SmartFindMixin*, *UnwrapperMixin*, *NameResolutionMixin*, *DataNormalizationMixin*, *SimplificationMixin*, *InspectMixin*, *ActionsMixinHigh*, *UnderconstrainedMixin*, *SizeConcretizationMixin*, *SizeNormalizationMixin*, *AddressConcretizationMixin*, *ActionsMixinLow*, *ConditionalMixin*, *ConvenientMappingsMixin*, *DirtyAddrsMixin*, *StackAllocationMixin*, *ClemoryBackerMixin*, *DictBackerMixin*, *PrivilegedPagingMixin*, *UltraPagesMixin*, *DefaultFillerMixin*, *SymbolicMergerMixin*, *PagedMemoryMixin*

**class** angr.storage.memory_mixins.**DictBackerMixin**

Bases: *PagedMemoryMixin*

**__init__**(*dict_memory_backer=None*, ***kwargs*)

**class** angr.storage.memory_mixins.**DirtyAddrsMixin**

Bases: *MemoryMixin*

**store**(*addr*, *data*, *size=None*, ***kwargs*)

**class** angr.storage.memory_mixins.**ExplicitFillerMixin**

Bases: *MemoryMixin*

**__init__**(*uninitialized_read_handler=None*, ***kwargs*)

**class** angr.storage.memory_mixins.**FastMemory**

Bases: *NameResolutionMixin*, *SimpleInterfaceMixin*, *SimplificationMixin*, *InspectMixin*, *ConditionalMixin*, *ExplicitFillerMixin*, *DefaultFillerMixin*, *SlottedMemoryMixin*

class angr.storage.memory_mixins.**HexDumperMixin**

Bases: *MemoryMixin*

**hex_dump**(*start*, *size*, *word_size=4*, *words_per_row=4*, *endianness='Iend_BE'*, *symbolic_char='?'*, *unprintable_char='.'*, *solve=False*, *extra_constraints=None*, *inspect=False*, *disable_actions=True*)

Returns a hex dump as a string. The solver, if enabled, is called once for every byte potentially making this function very slow. It is meant to be used mainly as a "visualization" for debugging.

Warning: May read and display more bytes than *size* due to rounding. Particularly, if size is less than, or not a multiple of word_size*words_per_line.

**Parameters**

- **start** – starting address from which to print
- **size** – number of bytes to display
- **word_size** – number of bytes to group together as one space-delimited unit
- **words_per_row** – number of words to display per row of output
- **endianness** – endianness to use when displaying each word (ASCII representation is unchanged)
- **symbolic_char** – the character to display when a byte is symbolic and has multiple solutions
- **unprintable_char** – the character to display when a byte is not printable
- **solve** – whether or not to attempt to solve (warning: can be very slow)
- **extra_constraints** – extra constraints to pass to the solver is solve is True
- **inspect** – whether or not to trigger SimInspect breakpoints for the memory load
- **disable_actions** – whether or not to disable SimActions for the memory load

**Returns**
hex dump as a string

class angr.storage.memory_mixins.**HistoryTrackingMixin**

Bases: *RefcountMixin*, *MemoryMixin*

Tracks the history of memory writes.

**__init__**(**args*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, ***kwargs*)

**parents**()

**changed_bytes**(*other*, ***kwargs*)

**Return type**
set[int] | None

**all_bytes_changed_in_history**()

**Return type**
SegmentList

class angr.storage.memory_mixins.**ISPOMixin**

Bases: *MemoryMixin*

An implementation of the International Stateless Persons Organisation, a mixin which should be applied as a bottom layer for memories which have no state and must redirect certain operations to a parent memory. Main usecase is for memory region classes which are stored within other memories, such as pages.

class angr.storage.memory_mixins.**InspectMixin**

Bases: *MemoryMixin*

This mixin adds support for the inspect plugin to the memory model.

Inspect breakpoints are called for the following events:

- mem_read (before and after)
- mem_write (before and after)
- reg_read (before and after)
- reg_write (before and after)
- address_concretization_add_constraints (before)

**store**(*addr*, *data*, *size=None*, ***, *condition=None*, *endness=None*, *inspect=True*, ***kwargs*)

**load**(*addr*, *size=None*, ***, *condition=None*, *endness=None*, *inspect=True*, ***kwargs*)

class angr.storage.memory_mixins.**JavaVmMemory**

Bases: *JavaVmMemoryMixin*

class angr.storage.memory_mixins.**JavaVmMemoryMixin**

Bases: *MemoryMixin*

A memory mixin for JavaVM memory.

**__init__**(*memory_id='mem'*, *stack=None*, *heap=None*, *vm_static_table=None*, *load_strategies=None*, *store_strategies=None*, *max_array_size=1000*, ***kwargs*)

**static get_new_uuid**()

Generate a unique id within the scope of the JavaVM memory. This, for example, is used for distinguishing memory objects of the same type (e.g. multiple instances of the same class).

**store**(*addr*, *data*, *frame=0*)

**load**(*addr*, *frame=0*, *none_if_missing=False*)

**push_stack_frame**()

**pop_stack_frame**()

**property stack**

**store_array_element**(*array*, *idx*, *value*)

**store_array_elements**(*array*, *start_idx*, *data*)

Stores either a single element or a range of elements in the array.

**Parameters**

- **array** – Reference to the array.
- **start_idx** – Starting index for the store.

- **data** – Either a single value or a list of values.

**load_array_element**(*array*, *idx*)

**load_array_elements**(*array*, *start_idx*, *no_of_elements*)

Loads either a single element or a range of elements from the array.

**Parameters**

- **array** – Reference to the array.
- **start_idx** – Starting index for the load.
- **no_of_elements** – Number of elements to load.

**concretize_store_idx**(*idx*, *strategies=None*)

Concretizes a store index.

**Parameters**

- **idx** – An expression for the index.
- **strategies** – A list of concretization strategies (to override the default).
- **min_idx** – Minimum value for a concretized index (inclusive).
- **max_idx** – Maximum value for a concretized index (exclusive).

**Returns**

A list of concrete indexes.

**concretize_load_idx**(*idx*, *strategies=None*)

Concretizes a load index.

**Parameters**

- **idx** – An expression for the index.
- **strategies** – A list of concretization strategies (to override the default).
- **min_idx** – Minimum value for a concretized index (inclusive).
- **max_idx** – Maximum value for a concretized index (exclusive).

**Returns**

A list of concrete indexes.

**class** angr.storage.memory_mixins.**KeyValueMemory**

Bases: *KeyValueMemoryMixin*

**class** angr.storage.memory_mixins.**KeyValueMemoryMixin**

Bases: *MemoryMixin*

KeyValueMemoryMixin is a mixin that provides a simple key-value store for memory.

**__init__**(**args*, ***kwargs*)

**load**(*addr*, *size=None*, *none_if_missing=False*, ***kwargs*)

**store**(*addr*, *data*, *type_=None*, ***kwargs*)

**class** angr.storage.memory_mixins.**LabelMergerMixin**

Bases: *MemoryMixin*

A memory mixin for merging labels. Labels come from SimLabeledMemoryObject.

__init__(**args*, ***kwargs*)

class angr.storage.memory_mixins.**LabeledMemory**

Bases: *SizeNormalizationMixin*, *ListPagesWithLabelsMixin*, *DefaultFillerMixin*, *TopMergerMixin*, *LabelMergerMixin*, *PagedMemoryMixin*

LabeledMemory is used in static analysis. It allows storing values with labels, such as *Definition*.

class angr.storage.memory_mixins.**ListPage**

Bases: *MemoryObjectMixin*, *PageBase*

This class implements a page memory mixin with lists as the main content store.

__init__(*memory=None*, *content=None*, *sinkhole=None*, *mo_cmp=None*, ***kwargs*)

load(*addr*, *size=None*, *endness=None*, *page_addr=None*, *memory=None*, *cooperate=False*, ***kwargs*)

store(*addr*, *data*, *size=None*, *endness=None*, *memory=None*, *cooperate=False*, ***kwargs*)

changed_bytes(*other*, *page_addr=None*)

**Parameters**

- **other** (ListPage)
- **page_addr** (*int | None*)

class angr.storage.memory_mixins.**ListPagesMixin**

Bases: *PagedMemoryMixin*

PAGE_TYPE

alias of *ListPage*

class angr.storage.memory_mixins.**ListPagesWithLabelsMixin**

Bases: *LabeledPagesMixin*, *ListPagesMixin*

class angr.storage.memory_mixins.**MVListPage**

Bases: *MemoryObjectSetMixin*, *PageBase*

MVListPage allows storing multiple values at the same location.

Each store() may take a value or multiple values. Each load() returns an iterator of all values stored at that location.

__init__(*memory=None*, *content=None*, *sinkhole=None*, *mo_cmp=None*, ***kwargs*)

load(*addr*, *size=None*, *endness=None*, *page_addr=None*, *memory=None*, *cooperate=False*, ***kwargs*)

**Return type**
list[tuple[int, *SimMemoryObject* | *SimLabeledMemoryObject*]]

store(*addr*, *data*, *size=None*, *endness=None*, *memory=None*, *cooperate=False*, ***kwargs*)

subsumes(*other*, *page_addr=None*, *memory=None*, *changed_offsets=None*)

**Return type**
bool

**Parameters**

- **other** (MVListPage)
- **page_addr** (*int | None*)

**changed_bytes**(*other*, *page_addr=None*)

**Parameters**

- **other** (MVListPage)
- **page_addr** (*int | None*)

**content_gen**(*index*)

class angr.storage.memory_mixins.**MVListPagesMixin**

Bases: *PagedMemoryMixin*

**PAGE_TYPE**

alias of *MVListPage*

**__init__**(**args*, *skip_missing_values_during_merging=False*, ***kwargs*)

class angr.storage.memory_mixins.**MVListPagesWithLabelsMixin**

Bases: *LabeledPagesMixin*, *MVListPagesMixin*

class angr.storage.memory_mixins.**MemoryObjectMixin**

Bases: *CooperationBase*[*SimMemoryObject*]

Uses SimMemoryObjects in region storage. With this, load will return a list of tuple (address, MO) and store will take a MO.

class angr.storage.memory_mixins.**MemoryRegionMetaMixin**

Bases: *MemoryMixin*

**__init__**(*related_function_addr=None*, ***kwargs*)

**property is_stack**

**property related_function_addr**

**get_abstract_locations**(*addr*, *size*)

Get a list of abstract locations that is within the range of [addr, addr + size]

This implementation is pretty slow. But since this method won't be called frequently, we can live with the bad implementation for now.

**Parameters**

- **addr** – Starting address of the memory region.
- **size** – Size of the memory region, in bytes.

**Returns**

A list of covered AbstractLocation objects, or an empty list if there is none.

**store**(*addr*, *data*, *size=None*, ***, *bbl_addr=None*, *stmt_id=None*, *ins_addr=None*, *endness=None*, ***kwargs*)

**load**(*addr*, *size=None*, ***, *bbl_addr=None*, *stmt_idx=None*, *ins_addr=None*, ***kwargs*)

**dbg_print**(*indent=0*)

Print out debugging information

class angr.storage.memory_mixins.**MultiValueMergerMixin**

Bases: *MemoryMixin*

__init__(**args*, *element_limit=5*, *annotation_limit=256*, *top_func=None*, *is_top_func=None*, *phi_maker=None*, *merge_into_top=True*, ***kwargs*)

store(*addr*, *data*, *size=None*, ***kwargs*)

class angr.storage.memory_mixins.**MultiValuedMemory**

Bases: *SizeNormalizationMixin*, *MVListPagesMixin*, *DefaultFillerMixin*, *MultiValueMergerMixin*, *PagedMemoryMixin*, *PagedMemoryMultiValueMixin*

class angr.storage.memory_mixins.**NameResolutionMixin**

Bases: *MemoryMixin*

This mixin allows you to provide register names as load addresses, and will automatically translate this to an offset and size.

store(*addr*, *data*, *size=None*, ***kwargs*)

load(*addr*, *size=None*, ***kwargs*)

class angr.storage.memory_mixins.**PageBase**

Bases: *HistoryTrackingMixin*, *RefcountMixin*, *CooperationBase*, *ISPOMixin*, *PermissionsMixin*, *MemoryMixin*

This is a fairly succinct definition of the contract between PagedMemoryMixin and its constituent pages:

- Pages must implement the MemoryMixin model for loads, stores, copying, merging, etc
- However, loading/storing may not necessarily use the same data domain as PagedMemoryMixin. In order to do more efficient loads/stores across pages, we use the CooperationBase interface which allows the page class to determine how to generate and unwrap the objects which are actually stored.
- To support COW, we use the RefcountMixin and the ISPOMixin (which adds the contract element that `memory=self` be passed to every method call)
- Pages have permissions associated with them, stored in the PermissionsMixin.

Read the docstrings for each of the constituent classes to understand the nuances of their functionalities

class angr.storage.memory_mixins.**PagedMemoryMixin**

Bases: *MemoryMixin*[int | BV | *SimActionObject*, BV, int | BV | *SimActionObject*], Generic[PageType]

A bottom-level storage mechanism. Dispatches reads to individual pages, the type of which is the PAGE_TYPE class variable.

**SUPPORTS_CONCRETE_LOAD: bool = True**

**PAGE_TYPE: type[PageType]**

__init__(*page_size=4096*, *default_permissions=3*, *permissions_map=None*, *page_kwargs=None*, ***kwargs*)

load(*addr*, *size=None*, ***, *endness=None*, ***kwargs*)

**Parameters**

- **addr** (*int*)
- **size** (*int | None*)

**store**(*addr*, *data*, *size=None*, *, *endness=None*, ***kwargs*)

**Parameters**

- **addr** (*int*)
- **size** (*int | None*)

**subsumes**(*other*)

**Return type**
bool

**Parameters**
**other** (PagedMemoryMixin)

**permissions**(*addr*, *permissions=None*, ***kwargs*)

**map_region**(*addr*, *length*, *permissions*, *, *init_zero=False*, ***kwargs*)

**unmap_region**(*addr*, *length*, ***kwargs*)

**changed_bytes**(*other*)

**Return type**
set[int]

**changed_pages**(*other*)

**Return type**
dict[int, set[int] | None]

**flush_pages**(*white_list*)

Flush all pages not included in the *white_list* by removing their pages. Note, this will not wipe them from memory if they were backed by a memory_backer, it will simply reset them to their initial state. Returns the list of pages that were cleared consisting of *(addr, length)* tuples. :type white_list: :param white_list: white list of regions in the form of (start, end) to exclude from the flush :return: a list of memory page ranges that were flushed :rtype: list

**class** angr.storage.memory_mixins.**PagedMemoryMultiValueMixin**

Bases: *MemoryMixin*

Implement optimizations and fast accessors for the MultiValues-variant of Paged Memory.

**load_annotations**(*addr*, *size*, ***kwargs*)

**Parameters**

- **addr** (*int*)
- **size** (*int*)

**class** angr.storage.memory_mixins.**PermissionsMixin**

Bases: *MemoryMixin*

This mixin adds a permissions_bits field and properties for extracting the read/write/exec permissions. It does NOT add permissions checking.

**__init__**(*permissions=None*, ***kwargs*)

**Parameters**
**permissions** (*int | BV | None*)

property perm_read

property perm_write

property perm_exec

class angr.storage.memory_mixins.**PrivilegedPagingMixin**

Bases: *PagedMemoryMixin*

A mixin for paged memory models which will raise SimSegfaultExceptions if STRICT_PAGE_ACCESS is enabled and a segfault condition is detected.

Segfault conditions include: - getting a page for reading which is non-readable - getting a page for writing which is non-writable - creating a page

The latter condition means that this should be inserted under any mixins which provide other implementations of `_initialize_page`.

class angr.storage.memory_mixins.**RefcountMixin**

Bases: *MemoryMixin*

This mixin adds a locked reference counter and methods to manipulate it, to facilitate copy-on-write optimizations.

__init__(***kwargs*)

acquire_unique()

Call this function to return a version of this page which can be used for writing, which may or may not be the same object as before. If you use this you must immediately replace the shared reference you previously had with the new unique copy.

acquire_shared()

Call this function to indicate that this page has had a reference added to it and must be copied before it can be acquired uniquely again. Creating the object implicitly starts it with one shared reference.

**Return type**
None

release_shared()

Call this function to indicate that this page has had a shared reference to it released

**Return type**
None

class angr.storage.memory_mixins.**RegionCategoryMixin**

Bases: *MemoryMixin*

property category

reg, mem, or file.

**Type**
Return the category of this SimMemory instance. It can be one of the three following categories

class angr.storage.memory_mixins.**RegionedAddressConcretizationMixin**

Bases: *MemoryMixin*

__init__(*read_strategies=None*, *write_strategies=None*, ***kwargs*)

**class** angr.storage.memory_mixins.**RegionedMemory**

Bases: *RegionCategoryMixin*, *MemoryRegionMetaMixin*, *StaticFindMixin*, *UnwrapperMixin*, *NameResolutionMixin*, *DataNormalizationMixin*, *SimplificationMixin*, *SizeConcretizationMixin*, *SizeNormalizationMixin*, *AddressConcretizationMixin*, *ConvenientMappingsMixin*, *DirtyAddrsMixin*, *ClemoryBackerMixin*, *DictBackerMixin*, *UltraPagesMixin*, *DefaultFillerMixin*, *AbstractMergerMixin*, *PagedMemoryMixin*

**class** angr.storage.memory_mixins.**RegionedMemoryMixin**

Bases: *MemoryMixin*

Regioned memory. This mixin manages multiple memory regions. Each address is represented as a tuple of (region ID, offset into the region), which is called a regioned address.

Converting absolute addresses into regioned addresses: We map an absolute address to a region by looking up which region this address belongs to in the region map. Currently this is only enabled for stack. Heap support has not landed yet.

When start analyzing a function, the user should call set_stack_address_mapping() to create a new region mapping. Likewise, when exiting from a function, the user should cancel the previous mapping by calling unset_stack_address_mapping().

**__init__**(*write_targets_limit=2048*, *read_targets_limit=4096*, *stack_region_map=None*, *generic_region_map=None*, *stack_size=65536*, *cle_memory_backer=None*, *dict_memory_backer=None*, *regioned_memory_cls=None*, ***kwargs*)

**Parameters**

- **write_targets_limit** (*int*)
- **read_targets_limit** (*int*)
- **stack_region_map** (RegionMap | *None*)
- **generic_region_map** (RegionMap | *None*)
- **stack_size** (*int*)
- **cle_memory_backer** (*None*)
- **dict_memory_backer** (*dict* | *None*)
- **regioned_memory_cls** (type | *None*)

**load**(*addr*, *size=None*, ***, *endness=None*, *condition=None*, ***kwargs*)

**Parameters**

- **size** (*BV* | *int* | *None*)
- **condition** (*Bool* | *None*)

**store**(*addr*, *data*, *size=None*, ***, *endness=None*, ***kwargs*)

**Parameters**
**size** (*int* | *None*)

**find**(*addr*, *data*, *max_search*, ***kwargs*)

**Parameters**
**addr** (*int* | *Bits*)

**replace_all**(*old*, *new*)

**Parameters**

- **old** (*BV*)
- **new** (*BV*)

**set_stack_address_mapping**(*absolute_address*, *region_id*, *related_function_address=None*)

Create a new mapping between an absolute address (which is the base address of a specific stack frame) and a region ID.

**Parameters**

- **absolute_address** (int) – The absolute memory address.
- **region_id** (str) – The region ID.
- **related_function_address** (int | None) – Related function address.

**unset_stack_address_mapping**(*absolute_address*)

Remove a stack mapping.

**Parameters**

**absolute_address** (int) – An absolute memory address that is the base address of the stack frame to destroy.

**stack_id**(*function_address*)

Return a memory region ID for a function. If the default region ID exists in the region mapping, an integer will appended to the region name. In this way we can handle recursive function calls, or a function that appears more than once in the call frame.

This also means that *stack_id()* should only be called when creating a new stack frame for a function. You are not supposed to call this function every time you want to map a function address to a stack ID.

**Parameters**

**function_address** (int) – Address of the function.

**Return type**

str

**Returns**

ID of the new memory region.

**set_stack_size**(*size*)

**Parameters**

**size** (*int*)

**class** angr.storage.memory_mixins.**SimpleInterfaceMixin**

Bases: *MemoryMixin*

**load**(*addr*, *size=None*, ***, *endness=None*, *condition=None*, *fallback=None*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, ***, *endness=None*, *condition=None*, ***kwargs*)

**class** angr.storage.memory_mixins.**SimplificationMixin**

Bases: *MemoryMixin*

**store**(*addr*, *data*, *size=None*, ***kwargs*)

class angr.storage.memory_mixins.**SizeConcretizationMixin**

Bases: *MemoryMixin*

This mixin allows memory to process symbolic sizes. It will not touch any sizes which are not ASTs with non-BVV ops. Assumes that the data is a BV.

- symbolic load sizes will be concretized as their maximum and a warning will be logged
- symbolic store sizes will be dispatched as several conditional stores with concrete sizes

**__init__**(*concretize_symbolic_write_size=False*, *max_concretize_count=256*, *max_symbolic_size=4194304*, *raise_memory_limit_error=False*, *size_limit=257*, ***kwargs*)

**Parameters**

- **concretize_symbolic_write_size** (*bool*)
- **max_concretize_count** (*int | None*)
- **max_symbolic_size** (*int*)
- **raise_memory_limit_error** (*bool*)
- **size_limit** (*int*)

**load**(*addr*, *size=None*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, ***, *condition=None*, ***kwargs*)

class angr.storage.memory_mixins.**SizeNormalizationMixin**

Bases: *MemoryMixin*

Provides basic services related to normalizing sizes. After this mixin, sizes will always be a plain int. Assumes that the data is a BV.

- load will throw a TypeError if no size is provided
- store will default to len(data)//byte_width if no size is provided

**load**(*addr*, *size=None*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, ***kwargs*)

class angr.storage.memory_mixins.**SlottedMemoryMixin**

Bases: *MemoryMixin*

**__init__**(*width=None*, ***kwargs*)

**load**(*addr*, *size=None*, ***, *endness=None*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, ***, *endness=None*, ***kwargs*)

**changed_bytes**(*other*)

class angr.storage.memory_mixins.**SmartFindMixin**

Bases: *MemoryMixin*

Memory mixin providing basic searching over concrete and symbolic data.

**find**(*addr*, *data*, *max_search*, ***, *default=None*, *endness=None*, *chunk_size=None*, *max_symbolic_bytes=None*, *condition=None*, *char_size=1*, ***kwargs*)

class angr.storage.memory_mixins.**SpecialFillerMixin**

Bases: *MemoryMixin*

**__init__**(*special_memory_filler=None*, ***kwargs*)

class angr.storage.memory_mixins.**StackAllocationMixin**

Bases: *PagedMemoryMixin*

This mixin adds automatic allocation for a stack region based on the stack_end and stack_size parameters.

**__init__**(*stack_end=None*, *stack_size=None*, *stack_perms=None*, ***kwargs*)

**allocate_stack_pages**(*addr*, *size*, ***kwargs*)

Pre-allocates pages for the stack without triggering any logic related to reading from them.

**Parameters**

- **addr** (int) – The highest address that should be mapped
- **size** (int) – The number of bytes to be allocated. byte 1 is the one at addr, byte 2 is the one before that, and so on.

**Returns**

A list of the new page objects

class angr.storage.memory_mixins.**StaticFindMixin**

Bases: *SmartFindMixin*

Implements data finding for abstract memory.

**find**(*addr*, *data*, *max_search*, ***, *default=None*, *endness=None*, *chunk_size=None*, *max_symbolic_bytes=None*, *condition=None*, *char_size=1*, ***kwargs*)

class angr.storage.memory_mixins.**SymbolicMergerMixin**

Bases: *MemoryMixin*

class angr.storage.memory_mixins.**TopMergerMixin**

Bases: *MemoryMixin*

A memory mixin for merging values in memory to TOP.

**__init__**(**args*, *top_func=None*, ***kwargs*)

class angr.storage.memory_mixins.**UltraPage**

Bases: *MemoryObjectMixin*, *PageBase*

Default page implementation

**SUPPORTS_CONCRETE_LOAD: bool = True**

**__init__**(*memory=None*, *init_zero=False*, ***kwargs*)

**classmethod new_from_shared**(*data*, *memory=None*, ***kwargs*)

**load**(*addr*, *size=None*, *page_addr=None*, *endness=None*, *memory=None*, *cooperate=False*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, *endness=None*, *memory=None*, *page_addr=None*, *cooperate=False*, ***kwargs*)

**Parameters**

- **data** (*int* | SimMemoryObject)

- **size** (*int | None*)

**concrete_run_length**(*addr*, *size*, ***kwargs*)

Return the number of concrete bytes at addr, capped at size.

**Return type**
int

**changed_bytes**(*other*, *page_addr=None*)

**Return type**
set[int]

**replace_all_with_offsets**(*offsets*, *old*, *new*, *memory=None*)

**Parameters**

- **offsets** (*Iterable[int]*)
- **old** (*BV*)
- **new** (*BV*)

**class** angr.storage.memory_mixins.**UltraPagesMixin**

Bases: *PagedMemoryMixin*

**PAGE_TYPE**

alias of *UltraPage*

**class** angr.storage.memory_mixins.**UnderconstrainedMixin**

Bases: *MemoryMixin*

**__init__**(**args*, ***kwargs*)

**load**(*addr*, *size=None*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, ***kwargs*)

**class** angr.storage.memory_mixins.**UnwrapperMixin**

Bases: *MemoryMixin*

This mixin processes SimActionObjects by passing on their .ast field.

**store**(*addr*, *data*, *size=None*, ***, *condition=None*, ***kwargs*)

**load**(*addr*, *size=None*, ***, *condition=None*, *fallback=None*, ***kwargs*)

**find**(*addr*, *data*, *max_search*, ***, *default=None*, ***kwargs*)

### angr.storage.memory_mixins.actions_mixin

**class** angr.storage.memory_mixins.actions_mixin.**ActionsMixinHigh**

Bases: *MemoryMixin*

**load**(*addr*, *size=None*, ***, *condition=None*, *fallback=None*, *disable_actions=False*, *action=None*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, ***, *disable_actions=False*, *action=None*, *condition=None*, ***kwargs*)

**class** angr.storage.memory_mixins.actions_mixin.**ActionsMixinLow**

Bases: *MemoryMixin*

**load**(*addr*, *size=None*, ***, *action=None*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, ***, *action=None*, ***kwargs*)

**Parameters**
**action** (SimActionData | *None*)

### angr.storage.memory_mixins.address_concretization_mixin

**class** angr.storage.memory_mixins.address_concretization_mixin.**MultiwriteAnnotation**

Bases: Annotation

**eliminatable = False**

**relocatable = True**

**class** angr.storage.memory_mixins.address_concretization_mixin.**AddressConcretizationMixin**

Bases: *MemoryMixin*

The address concretization mixin allows symbolic reads and writes to be handled sanely by dispatching them as a number of conditional concrete reads/writes. It provides a "concretization strategies" interface allowing the process of serializing symbolic addresses into concrete ones to be specified.

**__init__**(*read_strategies=None*, *write_strategies=None*, ***kwargs*)

**concretize_write_addr**(*addr*, *strategies=None*, *condition=None*)

Concretizes an address meant for writing.

**Parameters**

- **addr** – An expression for the address.
- **strategies** – A list of concretization strategies (to override the default).
- **condition** – Any extra constraints that should be observed when determining address satisfiability

**Returns**

A list of concrete addresses.

**concretize_read_addr**(*addr*, *strategies=None*, *condition=None*)

Concretizes an address meant for reading.

**Parameters**

- **addr** – An expression for the address.
- **strategies** – A list of concretization strategies (to override the default).

**Returns**

A list of concrete addresses.

**load**(*addr*, *size=None*, ***, *condition=None*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, ***, *condition=None*, ***kwargs*)

**permissions**(*addr*, *permissions=None*, ***kwargs*)

**map_region**(*addr*, *length*, *permissions*, ***kwargs*)

**unmap_region**(*addr*, *length*, ***kwargs*)

### angr.storage.memory_mixins.bvv_conversion_mixin

**class** angr.storage.memory_mixins.bvv_conversion_mixin.**DataNormalizationMixin**

Bases: *MemoryMixin*

Normalizes the data field for a store and the fallback field for a load to be BVs.

**store**(*addr*, *data*, *size=None*, ***kwargs*)

**load**(*addr*, *size=None*, ***, *fallback=None*, ***kwargs*)

### angr.storage.memory_mixins.conditional_store_mixin

**class** angr.storage.memory_mixins.conditional_store_mixin.**ConditionalMixin**

Bases: *MemoryMixin*

**load**(*addr*, *size=None*, ***, *condition=None*, *fallback=None*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, ***, *condition=None*, ***kwargs*)

### angr.storage.memory_mixins.convenient_mappings_mixin

**class** angr.storage.memory_mixins.convenient_mappings_mixin.**ConvenientMappingsMixin**

Bases: *MemoryMixin*

Implements mappings between names and hashes of symbolic variables and these variables themselves.

**__init__**(***kwargs*)

**store**(*addr*, *data*, *size=None*, ***kwargs*)

**get_symbolic_addrs**()

**addrs_for_name**(*n*)

Returns addresses that contain expressions that contain a variable named *n*.

**addrs_for_hash**(*h*)

Returns addresses that contain expressions that contain a variable with the hash of *h*.

**replace_all**(*old*, *new*)

Replaces all instances of expression *old* with expression *new*.

**Parameters**

- **old** (BV) – A claripy expression. Must contain at least one named variable (to make it possible to use the name index for speedup).
- **new** (BV) – The new variable to replace it with.

### angr.storage.memory_mixins.default_filler_mixin

**class** angr.storage.memory_mixins.default_filler_mixin.**DefaultFillerMixin**

Bases: *MemoryMixin*

**class** angr.storage.memory_mixins.default_filler_mixin.**SpecialFillerMixin**

Bases: *MemoryMixin*

**__init__**(*special_memory_filler=None*, ***kwargs*)

**class** angr.storage.memory_mixins.default_filler_mixin.**ExplicitFillerMixin**

Bases: *MemoryMixin*

**__init__**(*uninitialized_read_handler=None*, ***kwargs*)

### angr.storage.memory_mixins.dirty_addrs_mixin

**class** angr.storage.memory_mixins.dirty_addrs_mixin.**DirtyAddrsMixin**

Bases: *MemoryMixin*

**store**(*addr*, *data*, *size=None*, ***kwargs*)

### angr.storage.memory_mixins.hex_dumper_mixin

**class** angr.storage.memory_mixins.hex_dumper_mixin.**HexDumperMixin**

Bases: *MemoryMixin*

**hex_dump**(*start*, *size*, *word_size=4*, *words_per_row=4*, *endianness='Iend_BE'*, *symbolic_char='?'*, *unprintable_char='.'*, *solve=False*, *extra_constraints=None*, *inspect=False*, *disable_actions=True*)

Returns a hex dump as a string. The solver, if enabled, is called once for every byte potentially making this function very slow. It is meant to be used mainly as a "visualization" for debugging.

Warning: May read and display more bytes than *size* due to rounding. Particularly, if size is less than, or not a multiple of word_size*words_per_line.

**Parameters**

- **start** – starting address from which to print
- **size** – number of bytes to display
- **word_size** – number of bytes to group together as one space-delimited unit
- **words_per_row** – number of words to display per row of output
- **endianness** – endianness to use when displaying each word (ASCII representation is unchanged)
- **symbolic_char** – the character to display when a byte is symbolic and has multiple solutions
- **unprintable_char** – the character to display when a byte is not printable
- **solve** – whether or not to attempt to solve (warning: can be very slow)
- **extra_constraints** – extra constraints to pass to the solver is solve is True
- **inspect** – whether or not to trigger SimInspect breakpoints for the memory load
- **disable_actions** – whether or not to disable SimActions for the memory load

**Returns**

hex dump as a string

### angr.storage.memory_mixins.inspect_mixin

**class** angr.storage.memory_mixins.inspect_mixin.**InspectMixin**

Bases: *MemoryMixin*

This mixin adds support for the inspect plugin to the memory model.

Inspect breakpoints are called for the following events:

- mem_read (before and after)
- mem_write (before and after)
- reg_read (before and after)
- reg_write (before and after)
- address_concretization_add_constraints (before)

**store**(*addr*, *data*, *size=None*, ***, *condition=None*, *endness=None*, *inspect=True*, ***kwargs*)

**load**(*addr*, *size=None*, ***, *condition=None*, *endness=None*, *inspect=True*, ***kwargs*)

### angr.storage.memory_mixins.javavm_memory_mixin

**class** angr.storage.memory_mixins.javavm_memory_mixin.**JavaVmMemoryMixin**

Bases: *MemoryMixin*

A memory mixin for JavaVM memory.

**__init__**(*memory_id='mem'*, *stack=None*, *heap=None*, *vm_static_table=None*, *load_strategies=None*, *store_strategies=None*, *max_array_size=1000*, ***kwargs*)

**static get_new_uuid**()

Generate a unique id within the scope of the JavaVM memory. This, for example, is used for distinguishing memory objects of the same type (e.g. multiple instances of the same class).

**store**(*addr*, *data*, *frame=0*)

**load**(*addr*, *frame=0*, *none_if_missing=False*)

**push_stack_frame**()

**pop_stack_frame**()

**property stack**

**store_array_element**(*array*, *idx*, *value*)

**store_array_elements**(*array*, *start_idx*, *data*)

Stores either a single element or a range of elements in the array.

**Parameters**

- **array** – Reference to the array.
- **start_idx** – Starting index for the store.
- **data** – Either a single value or a list of values.

**load_array_element**(*array*, *idx*)

**load_array_elements**(*array*, *start_idx*, *no_of_elements*)

Loads either a single element or a range of elements from the array.

**Parameters**

- **array** – Reference to the array.
- **start_idx** – Starting index for the load.
- **no_of_elements** – Number of elements to load.

**concretize_store_idx**(*idx*, *strategies=None*)

Concretizes a store index.

**Parameters**

- **idx** – An expression for the index.
- **strategies** – A list of concretization strategies (to override the default).
- **min_idx** – Minimum value for a concretized index (inclusive).
- **max_idx** – Maximum value for a concretized index (exclusive).

**Returns**

A list of concrete indexes.

**concretize_load_idx**(*idx*, *strategies=None*)

Concretizes a load index.

**Parameters**

- **idx** – An expression for the index.
- **strategies** – A list of concretization strategies (to override the default).
- **min_idx** – Minimum value for a concretized index (inclusive).
- **max_idx** – Maximum value for a concretized index (exclusive).

**Returns**

A list of concrete indexes.

### angr.storage.memory_mixins.keyvalue_memory_mixin

**class** angr.storage.memory_mixins.keyvalue_memory_mixin.**TypedVariable**

Bases: object

TypedVariable is a simple class that holds a value and a type.

**__init__**(*type_*, *value*)

**type**

**value**

**class** angr.storage.memory_mixins.keyvalue_memory_mixin.**KeyValueMemoryMixin**

Bases: *MemoryMixin*

KeyValueMemoryMixin is a mixin that provides a simple key-value store for memory.

**__init__**(**args*, ***kwargs*)

**load**(*addr*, *size=None*, *none_if_missing=False*, ***kwargs*)

**store**(*addr*, *data*, *type_=None*, ***kwargs*)

### angr.storage.memory_mixins.label_merger_mixin

**class** angr.storage.memory_mixins.label_merger_mixin.**LabelMergerMixin**

Bases: *MemoryMixin*

A memory mixin for merging labels. Labels come from SimLabeledMemoryObject.

**__init__**(**args*, ***kwargs*)

### angr.storage.memory_mixins.memory_mixin

**class** angr.storage.memory_mixins.memory_mixin.**MemoryMixin**

Bases: *SimStatePlugin*, Generic[InData, OutData, Addr]

MemoryMixin is the base class for the memory model in angr. It provides a set of methods that should be implemented by memory models. This is done using mixins, where each mixin handles some specific feature of the memory model, only overriding methods that it needs to implement its function. The memory model class itself then combines a set of mixins using inheritence to form the final memory model class.

**SUPPORTS_CONCRETE_LOAD: bool = False**

__init__(*memory_id=None*, *endness='Iend_BE'*)

**Parameters**

- **memory_id** (*str | None*)
- **endness** (*str*)

property category: str

reg, mem, or file.

**Type**
Return the category of this SimMemory instance. It can be one of the three following categories

property variable_key_prefix: tuple[Any, ...]

find(*addr*, *data*, *max_search*, ***kwargs*)

**Return type**
tuple[Addr, list[Bool], list[int]]

**Parameters**

- **addr** (*Addr*)
- **data** (*InData*)
- **max_search** (*int*)

load(*addr*, *size=None*, ***kwargs*)

**Return type**
OutData

**Parameters**

- **addr** (*Addr*)
- **size** (*InData | None*)

store(*addr*, *data*, *size=None*, ***kwargs*)

**Return type**
None

**Parameters**

- **addr** (*Addr*)
- **data** (*InData*)
- **size** (*InData | None*)

MERGE_WHOLE_OBJECTS = False

widen(*others*)

Widen this memory with others. Only abstract (VSA) memories implement real widening; everything else merges.

**Return type**
bool

**Parameters**
**others** (*list[Self]*)

**subsumes**(*other*)

**Return type**
bool

**Parameters**
**other** (*Self*)

**permissions**(*addr*, *permissions=None*, ***kwargs*)

**Return type**
BV

**Parameters**

- **addr** (*Addr*)
- **permissions** (*int | claripy.ast.BV | None*)

**map_region**(*addr*, *length*, *permissions*, ***, *init_zero=False*, ***kwargs*)

**Parameters**

- **addr** (*Addr*)
- **length** (*int*)
- **permissions** (*int | claripy.ast.BV*)
- **init_zero** (*bool*)

**unmap_region**(*addr*, *length*, ***kwargs*)

**Parameters**

- **addr** (*Addr*)
- **length** (*int*)

**concrete_load**(*addr*, *size*, *writing=False*, ***kwargs*)

Set SUPPORTS_CONCRETE_LOAD to True and implement concrete_load if reading concrete bytes is faster in this memory model.

**Parameters**

- **addr** – The address to load from.
- **size** – Size of the memory read.
- **writing**

**Return type**
Any

**Returns**
A memoryview into the loaded bytes.

**concrete_run_length**(*addr*, *size*, ***kwargs*)

Return the number of concrete bytes starting at `addr`, capped at `size`.

**Return type**
int

**erase**(*addr*, *size=None*, ***kwargs*)

Set [addr:addr+size) to uninitialized. In many cases this will be faster than overwriting those locations with new values. This is commonly used during static data flow analysis.

**Parameters**

- **addr** (Addr) – The address to start erasing.
- **size** (int | None) – The number of bytes for erasing.

**Return type**
None

**Returns**
None

**replace_all**(*old*, *new*)

**Parameters**

- **old** (*BV*)
- **new** (*BV*)

**copy_contents**(*dst*, *src*, *size*, *condition=None*, ***kwargs*)

Override this method to provide faster copying of large chunks of data.

**Parameters**

- **dst** (Addr) – The destination of copying.
- **src** (Addr) – The source of copying.
- **size** (InData) – The size of copying.
- **condition** (Bool | None) – The storing condition.
- **kwargs** – Other parameters.

**Returns**
None

### angr.storage.memory_mixins.multi_value_merger_mixin

**class** angr.storage.memory_mixins.multi_value_merger_mixin.**MultiValueMergerMixin**

Bases: *MemoryMixin*

**__init__**(**args*, *element_limit=5*, *annotation_limit=256*, *top_func=None*, *is_top_func=None*, *phi_maker=None*, *merge_into_top=True*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, ***kwargs*)

### angr.storage.memory_mixins.name_resolution_mixin

**class** angr.storage.memory_mixins.name_resolution_mixin.**NameResolutionMixin**

Bases: *MemoryMixin*

This mixin allows you to provide register names as load addresses, and will automatically translate this to an offset and size.

**store**(*addr*, *data*, *size=None*, ***kwargs*)

**load**(*addr*, *size=None*, ***kwargs*)

### angr.storage.memory_mixins.paged_memory

### Submodules

page_backer_mixins
paged_memory_mixin
paged_memory_multivalue_mixin
pages
privileged_mixin
stack_allocation_mixin

### angr.storage.memory_mixins.paged_memory.page_backer_mixins

**class** angr.storage.memory_mixins.paged_memory.page_backer_mixins.**NotMemoryview**

Bases: object

**__init__**(*obj*, *offset*, *size*)

**class** angr.storage.memory_mixins.paged_memory.page_backer_mixins.**ClemoryBackerMixin**

Bases: *PagedMemoryMixin*

**__init__**(*cle_memory_backer=None*, ***kwargs*)

**Parameters**
**cle_memory_backer** (*Loader | Clemory | None*)

**class** angr.storage.memory_mixins.paged_memory.page_backer_mixins.**DictBackerMixin**

Bases: *PagedMemoryMixin*

**__init__**(*dict_memory_backer=None*, ***kwargs*)

### angr.storage.memory_mixins.paged_memory.paged_memory_mixin

**class** angr.storage.memory_mixins.paged_memory.paged_memory_mixin.**PagedMemoryMixin**

Bases: *MemoryMixin*[int | BV | *SimActionObject*, BV, int | BV | *SimActionObject*], Generic[PageType]

A bottom-level storage mechanism. Dispatches reads to individual pages, the type of which is the PAGE_TYPE class variable.

**SUPPORTS_CONCRETE_LOAD: bool = True**

**PAGE_TYPE: type[PageType]**

**__init__**(*page_size=4096*, *default_permissions=3*, *permissions_map=None*, *page_kwargs=None*, ***kwargs*)

**load**(*addr*, *size=None*, ***, *endness=None*, ***kwargs*)

**Parameters**

- **addr** (*int*)
- **size** (*int | None*)

**store**(*addr*, *data*, *size=None*, ***, *endness=None*, ***kwargs*)

**Parameters**

- **addr** (*int*)

- **size** (*int | None*)

**subsumes**(*other*)

**Return type**
bool

**Parameters**
**other** (PagedMemoryMixin)

**permissions**(*addr*, *permissions=None*, ***kwargs*)

**map_region**(*addr*, *length*, *permissions*, ***, *init_zero=False*, ***kwargs*)

**unmap_region**(*addr*, *length*, ***kwargs*)

**changed_bytes**(*other*)

**Return type**
set[int]

**changed_pages**(*other*)

**Return type**
dict[int, set[int] | None]

**flush_pages**(*white_list*)

Flush all pages not included in the *white_list* by removing their pages. Note, this will not wipe them from memory if they were backed by a memory_backer, it will simply reset them to their initial state. Returns the list of pages that were cleared consisting of *(addr, length)* tuples. :type white_list: :param white_list: white list of regions in the form of (start, end) to exclude from the flush :return: a list of memory page ranges that were flushed :rtype: list

**class** angr.storage.memory_mixins.paged_memory.paged_memory_mixin.**LabeledPagesMixin**

Bases: *PagedMemoryMixin*

**load_with_labels**(*addr*, *size=None*, *endness=None*, ***kwargs*)

**Return type**
tuple[Base, tuple[tuple[int, int, int, Any]]]

**Parameters**

- **addr** (*int*)
- **size** (*int | None*)

**class** angr.storage.memory_mixins.paged_memory.paged_memory_mixin.**ListPagesMixin**

Bases: *PagedMemoryMixin*

**PAGE_TYPE**

alias of *ListPage*

**class** angr.storage.memory_mixins.paged_memory.paged_memory_mixin.**MVListPagesMixin**

Bases: *PagedMemoryMixin*

**PAGE_TYPE**

alias of *MVListPage*

**__init__**(**args*, *skip_missing_values_during_merging=False*, ***kwargs*)

**class** angr.storage.memory_mixins.paged_memory.paged_memory_mixin.**ListPagesWithLabelsMixin**

Bases: *LabeledPagesMixin*, *ListPagesMixin*

**class** angr.storage.memory_mixins.paged_memory.paged_memory_mixin.**MVListPagesWithLabelsMixin**

Bases: *LabeledPagesMixin*, *MVListPagesMixin*

**class** angr.storage.memory_mixins.paged_memory.paged_memory_mixin.**UltraPagesMixin**

Bases: *PagedMemoryMixin*

**PAGE_TYPE**

alias of *UltraPage*

### angr.storage.memory_mixins.paged_memory.paged_memory_multivalue_mixin

**class** angr.storage.memory_mixins.paged_memory.paged_memory_multivalue_mixin.**PagedMemoryMultiValueMixin**

Bases: *MemoryMixin*

Implement optimizations and fast accessors for the MultiValues-variant of Paged Memory.

**load_annotations**(*addr*, *size*, ***kwargs*)

**Parameters**

- **addr** (*int*)
- **size** (*int*)

### angr.storage.memory_mixins.paged_memory.pages

**class** angr.storage.memory_mixins.paged_memory.pages.**CooperationBase**

Bases: Generic[T]

Any given subclass of this class which is not a subclass of MemoryMixin should have the property that any subclass it which *is* a subclass of MemoryMixin should all work with the same datatypes

**class** angr.storage.memory_mixins.paged_memory.pages.**HistoryTrackingMixin**

Bases: *RefcountMixin*, *MemoryMixin*

Tracks the history of memory writes.

**__init__**(**args*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, ***kwargs*)

**parents**()

**changed_bytes**(*other*, ***kwargs*)

**Return type**
set[int] | None

**all_bytes_changed_in_history**()

**Return type**
SegmentList

class angr.storage.memory_mixins.paged_memory.pages.**ISPOMixin**

Bases: *MemoryMixin*

An implementation of the International Stateless Persons Organisation, a mixin which should be applied as a bottom layer for memories which have no state and must redirect certain operations to a parent memory. Main usecase is for memory region classes which are stored within other memories, such as pages.

class angr.storage.memory_mixins.paged_memory.pages.**ListPage**

Bases: *MemoryObjectMixin*, *PageBase*

This class implements a page memory mixin with lists as the main content store.

**__init__**(*memory=None*, *content=None*, *sinkhole=None*, *mo_cmp=None*, ***kwargs*)

**load**(*addr*, *size=None*, *endness=None*, *page_addr=None*, *memory=None*, *cooperate=False*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, *endness=None*, *memory=None*, *cooperate=False*, ***kwargs*)

**changed_bytes**(*other*, *page_addr=None*)

**Parameters**

- **other** (ListPage)
- **page_addr** (*int | None*)

class angr.storage.memory_mixins.paged_memory.pages.**MVListPage**

Bases: *MemoryObjectSetMixin*, *PageBase*

MVListPage allows storing multiple values at the same location.

Each store() may take a value or multiple values. Each load() returns an iterator of all values stored at that location.

**__init__**(*memory=None*, *content=None*, *sinkhole=None*, *mo_cmp=None*, ***kwargs*)

**load**(*addr*, *size=None*, *endness=None*, *page_addr=None*, *memory=None*, *cooperate=False*, ***kwargs*)

**Return type**
list[tuple[int, *SimMemoryObject* | *SimLabeledMemoryObject*]]

**store**(*addr*, *data*, *size=None*, *endness=None*, *memory=None*, *cooperate=False*, ***kwargs*)

**subsumes**(*other*, *page_addr=None*, *memory=None*, *changed_offsets=None*)

**Return type**
bool

**Parameters**

- **other** (MVListPage)
- **page_addr** (*int | None*)

**changed_bytes**(*other*, *page_addr=None*)

**Parameters**

- **other** (MVListPage)
- **page_addr** (*int | None*)

**content_gen**(*index*)

**class** angr.storage.memory_mixins.paged_memory.pages.**MemoryObjectMixin**

Bases: *CooperationBase*[*SimMemoryObject*]

Uses SimMemoryObjects in region storage. With this, load will return a list of tuple (address, MO) and store will take a MO.

**class** angr.storage.memory_mixins.paged_memory.pages.**PageBase**

Bases: *HistoryTrackingMixin*, *RefcountMixin*, *CooperationBase*, *ISPOMixin*, *PermissionsMixin*, *MemoryMixin*

This is a fairly succinct definition of the contract between PagedMemoryMixin and its constituent pages:

- Pages must implement the MemoryMixin model for loads, stores, copying, merging, etc
- However, loading/storing may not necessarily use the same data domain as PagedMemoryMixin. In order to do more efficient loads/stores across pages, we use the CooperationBase interface which allows the page class to determine how to generate and unwrap the objects which are actually stored.
- To support COW, we use the RefcountMixin and the ISPOMixin (which adds the contract element that `memory=self` be passed to every method call)
- Pages have permissions associated with them, stored in the PermissionsMixin.

Read the docstrings for each of the constituent classes to understand the nuances of their functionalities

**class** angr.storage.memory_mixins.paged_memory.pages.**PermissionsMixin**

Bases: *MemoryMixin*

This mixin adds a permissions_bits field and properties for extracting the read/write/exec permissions. It does NOT add permissions checking.

**__init__**(*permissions=None*, ***kwargs*)

**Parameters**
**permissions** (*int | BV | None*)

**property perm_read**

**property perm_write**

**property perm_exec**

**class** angr.storage.memory_mixins.paged_memory.pages.**RefcountMixin**

Bases: *MemoryMixin*

This mixin adds a locked reference counter and methods to manipulate it, to facilitate copy-on-write optimizations.

**__init__**(***kwargs*)

**acquire_unique**()

Call this function to return a version of this page which can be used for writing, which may or may not be the same object as before. If you use this you must immediately replace the shared reference you previously had with the new unique copy.

**acquire_shared**()

Call this function to indicate that this page has had a reference added to it and must be copied before it can be acquired uniquely again. Creating the object implicitly starts it with one shared reference.

**Return type**
None

**release_shared**()

Call this function to indicate that this page has had a shared reference to it released

**Return type**
None

class angr.storage.memory_mixins.paged_memory.pages.**UltraPage**

Bases: *MemoryObjectMixin*, *PageBase*

Default page implementation

**SUPPORTS_CONCRETE_LOAD: bool = True**

**__init__**(*memory=None*, *init_zero=False*, ***kwargs*)

**classmethod new_from_shared**(*data*, *memory=None*, ***kwargs*)

**load**(*addr*, *size=None*, *page_addr=None*, *endness=None*, *memory=None*, *cooperate=False*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, *endness=None*, *memory=None*, *page_addr=None*, *cooperate=False*, ***kwargs*)

**Parameters**

- **data** (*int | SimMemoryObject*)
- **size** (*int | None*)

**concrete_run_length**(*addr*, *size*, ***kwargs*)

Return the number of concrete bytes at `addr`, capped at `size`.

**Return type**
int

**changed_bytes**(*other*, *page_addr=None*)

**Return type**
set[int]

**replace_all_with_offsets**(*offsets*, *old*, *new*, *memory=None*)

**Parameters**

- **offsets** (*Iterable[int]*)
- **old** (*BV*)
- **new** (*BV*)

### angr.storage.memory_mixins.paged_memory.pages.base

**class** angr.storage.memory_mixins.paged_memory.pages.base.**PageBase**

Bases: *HistoryTrackingMixin*, *RefcountMixin*, *CooperationBase*, *ISPOMixin*, *PermissionsMixin*, *MemoryMixin*

This is a fairly succinct definition of the contract between PagedMemoryMixin and its constituent pages:

- Pages must implement the MemoryMixin model for loads, stores, copying, merging, etc
- However, loading/storing may not necessarily use the same data domain as PagedMemoryMixin. In order to do more efficient loads/stores across pages, we use the CooperationBase interface which allows the page class to determine how to generate and unwrap the objects which are actually stored.
- To support COW, we use the RefcountMixin and the ISPOMixin (which adds the contract element that `memory=self` be passed to every method call)
- Pages have permissions associated with them, stored in the PermissionsMixin.

Read the docstrings for each of the constituent classes to understand the nuances of their functionalities

### angr.storage.memory_mixins.paged_memory.pages.cooperation

**class** angr.storage.memory_mixins.paged_memory.pages.cooperation.**CooperationBase**

Bases: Generic[T]

Any given subclass of this class which is not a subclass of MemoryMixin should have the property that any subclass it which *is* a subclass of MemoryMixin should all work with the same datatypes

**class** angr.storage.memory_mixins.paged_memory.pages.cooperation.**MemoryObjectMixin**

Bases: *CooperationBase*[*SimMemoryObject*]

Uses SimMemoryObjects in region storage. With this, load will return a list of tuple (address, MO) and store will take a MO.

**class** angr.storage.memory_mixins.paged_memory.pages.cooperation.**MemoryObjectSetMixin**

Bases: *CooperationBase*

Uses sets of SimMemoryObjects in region storage.

**class** angr.storage.memory_mixins.paged_memory.pages.cooperation.**BasicClaripyCooperation**

Bases: *CooperationBase*

Mix this (along with PageBase) into a storage class which supports loading and storing claripy bitvectors and it will be able to work as a page in the paged memory model.

### angr.storage.memory_mixins.paged_memory.pages.history_tracking_mixin

**class** angr.storage.memory_mixins.paged_memory.pages.history_tracking_mixin.**HistoryTrackingMixin**

Bases: *RefcountMixin*, *MemoryMixin*

Tracks the history of memory writes.

**__init__**(**args*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, ***kwargs*)

**parents**()

**changed_bytes**(*other*, ***kwargs*)

**Return type**
set[int] | None

**all_bytes_changed_in_history**()

**Return type**
SegmentList

### angr.storage.memory_mixins.paged_memory.pages.ispo_mixin

**exception** angr.storage.memory_mixins.paged_memory.pages.ispo_mixin.**MissingMemoryError**

Bases: Exception

Raised when a memory kwarg is not passed to a stateless object.

**class** angr.storage.memory_mixins.paged_memory.pages.ispo_mixin.**ISPOMixin**

Bases: *MemoryMixin*

An implementation of the International Stateless Persons Organisation, a mixin which should be applied as a bottom layer for memories which have no state and must redirect certain operations to a parent memory. Main usecase is for memory region classes which are stored within other memories, such as pages.

### angr.storage.memory_mixins.paged_memory.pages.list_page

**class** angr.storage.memory_mixins.paged_memory.pages.list_page.**ListPage**

Bases: *MemoryObjectMixin*, *PageBase*

This class implements a page memory mixin with lists as the main content store.

**__init__**(*memory=None*, *content=None*, *sinkhole=None*, *mo_cmp=None*, ***kwargs*)

**load**(*addr*, *size=None*, *endness=None*, *page_addr=None*, *memory=None*, *cooperate=False*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, *endness=None*, *memory=None*, *cooperate=False*, ***kwargs*)

**changed_bytes**(*other*, *page_addr=None*)

**Parameters**

- **other** (ListPage)
- **page_addr** (*int | None*)

### angr.storage.memory_mixins.paged_memory.pages.multi_values

**class** angr.storage.memory_mixins.paged_memory.pages.multi_values.**MultiValues**

Bases: object

Represents a byte vector where each byte can have one or multiple values.

As an implementation optimization (so that we do not create excessive sets and dicts), self._single_value stores a claripy AST when this MultiValues object represents only one value at offset 0.

__init__(*v=None*)

**Parameters**
**v** (*BV | MultiValues | dict[int, set[BV]] | None*)

add_value(*offset*, *value*)

**Return type**
None

**Parameters**

- **offset** (*int*)
- **value** (*BV*)

one_value(*strip_annotations=False*)

**Return type**
BV | None

**Parameters**
**strip_annotations** (*bool*)

merge(*mv*)

**Return type**
*MultiValues*

**Parameters**
**mv** (MultiValues)

keys()

**Return type**
set[int]

values()

**Return type**
Iterator[set[BV]]

items()

**Return type**
Iterator[tuple[int, set[BV]]]

count()

**Return type**
int

extract(*offset*, *length*, *endness*)

**Return type**
*MultiValues*

**Parameters**

- **offset** (*int*)
- **length** (*int*)
- **endness** (*str*)

**concat**(*other*)

**Return type**
*MultiValues*

**Parameters**
**other** (MultiValues | *BV* | bytes)

### angr.storage.memory_mixins.paged_memory.pages.mv_list_page

**class** angr.storage.memory_mixins.paged_memory.pages.mv_list_page.**MVListPage**

Bases: *MemoryObjectSetMixin*, *PageBase*

MVListPage allows storing multiple values at the same location.

Each store() may take a value or multiple values. Each load() returns an iterator of all values stored at that location.

**__init__**(*memory=None*, *content=None*, *sinkhole=None*, *mo_cmp=None*, ***kwargs*)

**load**(*addr*, *size=None*, *endness=None*, *page_addr=None*, *memory=None*, *cooperate=False*, ***kwargs*)

**Return type**
list[tuple[int, *SimMemoryObject* | *SimLabeledMemoryObject*]]

**store**(*addr*, *data*, *size=None*, *endness=None*, *memory=None*, *cooperate=False*, ***kwargs*)

**subsumes**(*other*, *page_addr=None*, *memory=None*, *changed_offsets=None*)

**Return type**
bool

**Parameters**

- **other** (MVListPage)
- **page_addr** (*int* | *None*)

**changed_bytes**(*other*, *page_addr=None*)

**Parameters**

- **other** (MVListPage)
- **page_addr** (*int* | *None*)

**content_gen**(*index*)

### angr.storage.memory_mixins.paged_memory.pages.permissions_mixin

**class** angr.storage.memory_mixins.paged_memory.pages.permissions_mixin.**PermissionsMixin**

Bases: *MemoryMixin*

This mixin adds a permissions_bits field and properties for extracting the read/write/exec permissions. It does NOT add permissions checking.

**__init__**(*permissions=None*, ***kwargs*)

**Parameters**
**permissions** (*int* | *BV* | *None*)

**property perm_read**

property perm_write

property perm_exec

### angr.storage.memory_mixins.paged_memory.pages.refcount_mixin

class angr.storage.memory_mixins.paged_memory.pages.refcount_mixin.**RefcountMixin**

Bases: *MemoryMixin*

This mixin adds a locked reference counter and methods to manipulate it, to facilitate copy-on-write optimizations.

__init__(***kwargs*)

acquire_unique()

Call this function to return a version of this page which can be used for writing, which may or may not be the same object as before. If you use this you must immediately replace the shared reference you previously had with the new unique copy.

acquire_shared()

Call this function to indicate that this page has had a reference added to it and must be copied before it can be acquired uniquely again. Creating the object implicitly starts it with one shared reference.

**Return type**
None

release_shared()

Call this function to indicate that this page has had a shared reference to it released

**Return type**
None

### angr.storage.memory_mixins.paged_memory.pages.symbolic_bitmap

class angr.storage.memory_mixins.paged_memory.pages.symbolic_bitmap.**SymbolicBitmap**

Bases: object

Tracks, for every byte of an UltraPage, whether that byte is symbolic or not.

The map is stored as a bitmap where the i-th bit of the map lives in bit `i & 7` of byte `i >> 3` (least-significant bit first). This makes `int.from_bytes(..., "little")` a direct view of the map as a big integer and lets range scans be done with `bit_length()` instead of a Python-level loop.

A page whose map is uniform (all bytes are symbolic or concrete) does not store any map.

All ranges are half-open `[start, stop)` and are assumed to lie within `[0, size]`.

__init__(*size*, *value=0*)

**Parameters**

- **size** (*int*)
- **value** (*int*)

size

property nbytes: int

The number of bytes of backing store this map currently occupies (0 while uniform).

property uniform_value: int | None

Return 0/1 if every byte of the page has that symbolic-ness, or None if the map is mixed.

get(*i*)

Return 1 if byte `i` is symbolic, 0 otherwise.

**Return type**
int

**Parameters**
**i** (*int*)

set(*i*, *value*)

Mark byte `i` as symbolic (`value` truthy) or concrete.

**Return type**
None

**Parameters**

- **i** (*int*)
- **value** (*int*)

set_range(*start*, *stop*)

Mark `[start, stop)` as symbolic.

**Return type**
None

**Parameters**

- **start** (*int*)
- **stop** (*int*)

clear_range(*start*, *stop*)

Mark `[start, stop)` as concrete.

**Return type**
None

**Parameters**

- **start** (*int*)
- **stop** (*int*)

next_set(*start*, *stop*)

Return the smallest `i` in `[start, stop)` whose byte is symbolic, or `stop` if there is none.

A whole range is turned into one big integer and located with `(w & -w).bit_length()` rather than being walked bit by bit. Long ranges are probed 64 bits at a time first.

**Return type**
int

**Parameters**

- **start** (*int*)
- **stop** (*int*)

**next_clear**(*start*, *stop*)

Return the smallest `i` in `[start, stop)` whose byte is concrete, or `stop` if there is none.

**Return type**
int

**Parameters**

- **start** (*int*)
- **stop** (*int*)

**all_set**(*start*, *stop*)

Return True if every byte in `[start, stop)` is symbolic.

**Return type**
bool

**Parameters**

- **start** (*int*)
- **stop** (*int*)

**any_set**(*start*, *stop*)

Return True if any byte in `[start, stop)` is symbolic.

**Return type**
bool

**Parameters**

- **start** (*int*)
- **stop** (*int*)

**view**(*start*, *stop*)

Return the packed bits covering `[start, stop)`: bit `i` of the result is byte `start + i` of the page.

When `start` is byte-aligned, the result is a writable view of this map's own backing store, so a native consumer (e.g., unicorn engine) can update the page's symbolic-ness in place. Returning such a view pins the backing store: it may no longer be dropped in favor of the uniform representation.

An unaligned `start` cannot be expressed as a view of the backing store, so the bits are shifted into place and returned read-only. Consumers like unicorn engine should not use this view for writing!

**Return type**
memoryview

**Parameters**

- **start** (*int*)
- **stop** (*int*)

**copy**()

**Return type**
*SymbolicBitmap*

### angr.storage.memory_mixins.paged_memory.pages.ultra_page

class angr.storage.memory_mixins.paged_memory.pages.ultra_page.**UltraPage**

Bases: *MemoryObjectMixin*, *PageBase*

Default page implementation

**SUPPORTS_CONCRETE_LOAD: bool = True**

**__init__**(*memory=None*, *init_zero=False*, ***kwargs*)

**classmethod new_from_shared**(*data*, *memory=None*, ***kwargs*)

**load**(*addr*, *size=None*, *page_addr=None*, *endness=None*, *memory=None*, *cooperate=False*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, *endness=None*, *memory=None*, *page_addr=None*, *cooperate=False*, ***kwargs*)

**Parameters**

- **data** (*int | SimMemoryObject*)
- **size** (*int | None*)

**concrete_run_length**(*addr*, *size*, ***kwargs*)

Return the number of concrete bytes at addr, capped at size.

**Return type**
int

**changed_bytes**(*other*, *page_addr=None*)

**Return type**
set[int]

**replace_all_with_offsets**(*offsets*, *old*, *new*, *memory=None*)

**Parameters**

- **offsets** (*Iterable[int]*)
- **old** (*BV*)
- **new** (*BV*)

### angr.storage.memory_mixins.paged_memory.privileged_mixin

class angr.storage.memory_mixins.paged_memory.privileged_mixin.**PrivilegedPagingMixin**

Bases: *PagedMemoryMixin*

A mixin for paged memory models which will raise SimSegfaultExceptions if STRICT_PAGE_ACCESS is enabled and a segfault condition is detected.

Segfault conditions include: - getting a page for reading which is non-readable - getting a page for writing which is non-writable - creating a page

The latter condition means that this should be inserted under any mixins which provide other implementations of _initialize_page.

### angr.storage.memory_mixins.paged_memory.stack_allocation_mixin

**class** angr.storage.memory_mixins.paged_memory.stack_allocation_mixin.**StackAllocationMixin**

Bases: *PagedMemoryMixin*

This mixin adds automatic allocation for a stack region based on the stack_end and stack_size parameters.

**__init__**(*stack_end=None*, *stack_size=None*, *stack_perms=None*, ***kwargs*)

**allocate_stack_pages**(*addr*, *size*, ***kwargs*)

Pre-allocates pages for the stack without triggering any logic related to reading from them.

**Parameters**

- **addr** (int) – The highest address that should be mapped
- **size** (int) – The number of bytes to be allocated. byte 1 is the one at addr, byte 2 is the one before that, and so on.

**Returns**

A list of the new page objects

### angr.storage.memory_mixins.regioned_memory

**class** angr.storage.memory_mixins.regioned_memory.**AbstractMergerMixin**

Bases: *MemoryMixin*

AbstractMergerMixin handles merging initialized values.

**MERGE_WHOLE_OBJECTS = True**

**class** angr.storage.memory_mixins.regioned_memory.**MemoryRegionMetaMixin**

Bases: *MemoryMixin*

**__init__**(*related_function_addr=None*, ***kwargs*)

**property is_stack**

**property related_function_addr**

**get_abstract_locations**(*addr*, *size*)

Get a list of abstract locations that is within the range of [addr, addr + size]

This implementation is pretty slow. But since this method won't be called frequently, we can live with the bad implementation for now.

**Parameters**

- **addr** – Starting address of the memory region.
- **size** – Size of the memory region, in bytes.

**Returns**

A list of covered AbstractLocation objects, or an empty list if there is none.

**store**(*addr*, *data*, *size=None*, ***, *bbl_addr=None*, *stmt_id=None*, *ins_addr=None*, *endness=None*, ***kwargs*)

**load**(*addr*, *size=None*, ***, *bbl_addr=None*, *stmt_idx=None*, *ins_addr=None*, ***kwargs*)

**dbg_print**(*indent=0*)

Print out debugging information

class angr.storage.memory_mixins.regioned_memory.**RegionCategoryMixin**

Bases: *MemoryMixin*

**property category**

reg, mem, or file.

**Type**

Return the category of this SimMemory instance. It can be one of the three following categories

class angr.storage.memory_mixins.regioned_memory.**RegionedAddressConcretizationMixin**

Bases: *MemoryMixin*

**__init__**(*read_strategies=None*, *write_strategies=None*, ***kwargs*)

class angr.storage.memory_mixins.regioned_memory.**RegionedMemoryMixin**

Bases: *MemoryMixin*

Regioned memory. This mixin manages multiple memory regions. Each address is represented as a tuple of (region ID, offset into the region), which is called a regioned address.

Converting absolute addresses into regioned addresses: We map an absolute address to a region by looking up which region this address belongs to in the region map. Currently this is only enabled for stack. Heap support has not landed yet.

When start analyzing a function, the user should call set_stack_address_mapping() to create a new region mapping. Likewise, when exiting from a function, the user should cancel the previous mapping by calling unset_stack_address_mapping().

**__init__**(*write_targets_limit=2048*, *read_targets_limit=4096*, *stack_region_map=None*, *generic_region_map=None*, *stack_size=65536*, *cle_memory_backer=None*, *dict_memory_backer=None*, *regioned_memory_cls=None*, ***kwargs*)

**Parameters**

- **write_targets_limit** (*int*)
- **read_targets_limit** (*int*)
- **stack_region_map** (RegionMap | *None*)
- **generic_region_map** (RegionMap | *None*)
- **stack_size** (*int*)
- **cle_memory_backer** (*None*)
- **dict_memory_backer** (*dict* | *None*)
- **regioned_memory_cls** (*type* | *None*)

**load**(*addr*, *size=None*, ***, *endness=None*, *condition=None*, ***kwargs*)

**Parameters**

- **size** (*BV* | *int* | *None*)
- **condition** (*Bool* | *None*)

**store**(*addr*, *data*, *size=None*, ***, *endness=None*, ***kwargs*)

**Parameters**

**size** (*int* | *None*)

**find**(*addr*, *data*, *max_search*, ***kwargs*)

**Parameters**
**addr** (*int | Bits*)

**replace_all**(*old*, *new*)

**Parameters**

- **old** (*BV*)
- **new** (*BV*)

**set_stack_address_mapping**(*absolute_address*, *region_id*, *related_function_address=None*)

Create a new mapping between an absolute address (which is the base address of a specific stack frame) and a region ID.

**Parameters**

- **absolute_address** (int) – The absolute memory address.
- **region_id** (str) – The region ID.
- **related_function_address** (int | None) – Related function address.

**unset_stack_address_mapping**(*absolute_address*)

Remove a stack mapping.

**Parameters**
**absolute_address** (int) – An absolute memory address that is the base address of the stack frame to destroy.

**stack_id**(*function_address*)

Return a memory region ID for a function. If the default region ID exists in the region mapping, an integer will appended to the region name. In this way we can handle recursive function calls, or a function that appears more than once in the call frame.

This also means that *stack_id()* should only be called when creating a new stack frame for a function. You are not supposed to call this function every time you want to map a function address to a stack ID.

**Parameters**
**function_address** (int) – Address of the function.

**Return type**
str

**Returns**
ID of the new memory region.

**set_stack_size**(*size*)

**Parameters**
**size** (*int*)

**class** angr.storage.memory_mixins.regioned_memory.**StaticFindMixin**

Bases: *SmartFindMixin*

Implements data finding for abstract memory.

**find**(*addr*, *data*, *max_search*, ***, *default=None*, *endness=None*, *chunk_size=None*, *max_symbolic_bytes=None*, *condition=None*, *char_size=1*, ***kwargs*)

#### angr.storage.memory_mixins.regioned_memory.abstract_address_descriptor

**class** angr.storage.memory_mixins.regioned_memory.abstract_address_descriptor.**AbstractAddressDescriptor**

Bases: object

AbstractAddressDescriptor describes a list of region+offset tuples. It provides a convenient way for accessing the cardinality (the total number of addresses) without enumerating or creating all addresses in static mode.

**__init__**()

**property cardinality**

**add_regioned_address**(*region*, *addr*)

**Parameters**

- **region** (*str*)
- **addr** (*BV*)

**clear**()

#### angr.storage.memory_mixins.regioned_memory.abstract_merger_mixin

**class** angr.storage.memory_mixins.regioned_memory.abstract_merger_mixin.**AbstractMergerMixin**

Bases: *MemoryMixin*

AbstractMergerMixin handles merging initialized values.

**MERGE_WHOLE_OBJECTS = True**

#### angr.storage.memory_mixins.regioned_memory.region_category_mixin

**class** angr.storage.memory_mixins.regioned_memory.region_category_mixin.**RegionCategoryMixin**

Bases: *MemoryMixin*

**property category**

reg, mem, or file.

**Type**

Return the category of this SimMemory instance. It can be one of the three following categories

### angr.storage.memory_mixins.regioned_memory.region_data

class angr.storage.memory_mixins.regioned_memory.region_data.**AddressWrapper**

Bases: object

AddressWrapper is used in SimAbstractMemory, which provides extra meta information for an address (or a ValueSet object) that is normalized from an integer/BVV/StridedInterval.

**__init__**(*region*, *region_base_addr*, *address*, *is_on_stack*, *function_address*)

Constructor for the class AddressWrapper.

**Parameters**

- **region** (str) – Name of the memory regions it belongs to.
- **region_base_addr** (int) – Base address of the memory region
- **address** – An address (not a ValueSet object).
- **is_on_stack** (bool) – Whether this address is on a stack region or not.
- **function_address** (int | None) – Related function address (if any).

**region**

**region_base_addr**

**address**

**is_on_stack**

**function_address**

**to_valueset**(*state*)

Convert to a ValueSet instance

**Parameters**
**state** – A state

**Returns**
The converted ValueSet instance

class angr.storage.memory_mixins.regioned_memory.region_data.**RegionDescriptor**

Bases: object

Descriptor for a memory region ID.

**__init__**(*region_id*, *base_address*, *related_function_address=None*)

**region_id**

**base_address**

**related_function_address**

class angr.storage.memory_mixins.regioned_memory.region_data.**RegionMap**

Bases: object

Mostly used in SimAbstractMemory, RegionMap stores a series of mappings between concrete memory address ranges and memory regions, like stack frames and heap regions.

__init__(*is_stack*)

Constructor

**Parameters**
**is_stack** – Whether this is a region map for stack frames or not. Different strategies apply for stack regions.

property is_empty

property stack_base

property region_ids

copy(*memo*)

map(*absolute_address*, *region_id*, *related_function_address=None*)

Add a mapping between an absolute address and a region ID. If this is a stack region map, all stack regions beyond (lower than) this newly added regions will be discarded.

**Parameters**

- **absolute_address** – An absolute memory address.
- **region_id** – ID of the memory region.
- **related_function_address** – A related function address, mostly used for stack regions.

unmap_by_address(*absolute_address*)

Removes a mapping based on its absolute address.

**Parameters**
**absolute_address** – An absolute address

absolutize(*region_id*, *relative_address*)

Convert a relative address in some memory region to an absolute address.

**Parameters**

- **region_id** – The memory region ID
- **relative_address** – The relative memory offset in that memory region

**Returns**
An absolute address if converted, or an exception is raised when region id does not exist.

relativize(*absolute_address*, *target_region_id=None*)

Convert an absolute address to the memory offset in a memory region.

Note that if an address belongs to heap region is passed in to a stack region map, it will be converted to an offset included in the closest stack frame, and vice versa for passing a stack address to a heap region. Therefore you should only pass in address that belongs to the same category (stack or non-stack) of this region map.

**Parameters**
**absolute_address** – An absolute memory address

**Returns**
A tuple of the closest region ID, the relative offset, and the related function address.

### angr.storage.memory_mixins.regioned_memory.region_meta_mixin

**class** angr.storage.memory_mixins.regioned_memory.region_meta_mixin.**Segment**

Bases: object

Segment represents a continuous memory region.

**__init__**(*offset*, *size=0*)

**class** angr.storage.memory_mixins.regioned_memory.region_meta_mixin.**AbstractLocation**

Bases: object

AbstractLocation represents a location in memory.

**__init__**(*bbl_key*, *stmt_id*, *region_id*, *segment_list=None*, *region_offset=None*, *size=None*)

**property basicblock_key**

**property statement_id**

**property region**

**property segments**

**update**(*region_offset*, *size*)

**copy**()

**merge**(*other*)

**class** angr.storage.memory_mixins.regioned_memory.region_meta_mixin.**MemoryRegionMetaMixin**

Bases: *MemoryMixin*

**__init__**(*related_function_addr=None*, ***kwargs*)

**property is_stack**

**property related_function_addr**

**get_abstract_locations**(*addr*, *size*)

Get a list of abstract locations that is within the range of [addr, addr + size]

This implementation is pretty slow. But since this method won't be called frequently, we can live with the bad implementation for now.

**Parameters**

- **addr** – Starting address of the memory region.
- **size** – Size of the memory region, in bytes.

**Returns**

A list of covered AbstractLocation objects, or an empty list if there is none.

**store**(*addr*, *data*, *size=None*, ***, *bbl_addr=None*, *stmt_id=None*, *ins_addr=None*, *endness=None*, ***kwargs*)

**load**(*addr*, *size=None*, ***, *bbl_addr=None*, *stmt_idx=None*, *ins_addr=None*, ***kwargs*)

**dbg_print**(*indent=0*)

Print out debugging information

### angr.storage.memory_mixins.regioned_memory.regioned_address_concretization_mixin

**class** angr.storage.memory_mixins.regioned_memory.regioned_address_concretization_mixin.**RegionedAddressConcretizationMixin**

Bases: *MemoryMixin*

**__init__**(*read_strategies=None*, *write_strategies=None*, ***kwargs*)

### angr.storage.memory_mixins.regioned_memory.regioned_memory_mixin

**class** angr.storage.memory_mixins.regioned_memory.regioned_memory_mixin.**RegionedMemoryMixin**

Bases: *MemoryMixin*

Regioned memory. This mixin manages multiple memory regions. Each address is represented as a tuple of (region ID, offset into the region), which is called a regioned address.

Converting absolute addresses into regioned addresses: We map an absolute address to a region by looking up which region this address belongs to in the region map. Currently this is only enabled for stack. Heap support has not landed yet.

When start analyzing a function, the user should call set_stack_address_mapping() to create a new region mapping. Likewise, when exiting from a function, the user should cancel the previous mapping by calling unset_stack_address_mapping().

**__init__**(*write_targets_limit=2048*, *read_targets_limit=4096*, *stack_region_map=None*, *generic_region_map=None*, *stack_size=65536*, *cle_memory_backer=None*, *dict_memory_backer=None*, *regioned_memory_cls=None*, ***kwargs*)

**Parameters**

- **write_targets_limit** (*int*)
- **read_targets_limit** (*int*)
- **stack_region_map** (RegionMap | *None*)
- **generic_region_map** (RegionMap | *None*)
- **stack_size** (*int*)
- **cle_memory_backer** (*None*)
- **dict_memory_backer** (*dict* | *None*)
- **regioned_memory_cls** (type | *None*)

**load**(*addr*, *size=None*, ***, *endness=None*, *condition=None*, ***kwargs*)

**Parameters**

- **size** (*BV* | *int* | *None*)
- **condition** (*Bool* | *None*)

**store**(*addr*, *data*, *size=None*, ***, *endness=None*, ***kwargs*)

**Parameters**

**size** (*int* | *None*)

**find**(*addr*, *data*, *max_search*, ***kwargs*)

**Parameters**
**addr** (*int | Bits*)

**replace_all**(*old*, *new*)

**Parameters**

- **old** (*BV*)
- **new** (*BV*)

**set_stack_address_mapping**(*absolute_address*, *region_id*, *related_function_address=None*)

Create a new mapping between an absolute address (which is the base address of a specific stack frame) and a region ID.

**Parameters**

- **absolute_address** (int) – The absolute memory address.
- **region_id** (str) – The region ID.
- **related_function_address** (int | None) – Related function address.

**unset_stack_address_mapping**(*absolute_address*)

Remove a stack mapping.

**Parameters**
**absolute_address** (int) – An absolute memory address that is the base address of the stack frame to destroy.

**stack_id**(*function_address*)

Return a memory region ID for a function. If the default region ID exists in the region mapping, an integer will appended to the region name. In this way we can handle recursive function calls, or a function that appears more than once in the call frame.

This also means that *stack_id()* should only be called when creating a new stack frame for a function. You are not supposed to call this function every time you want to map a function address to a stack ID.

**Parameters**
**function_address** (int) – Address of the function.

**Return type**
str

**Returns**
ID of the new memory region.

**set_stack_size**(*size*)

**Parameters**
**size** (*int*)

### angr.storage.memory_mixins.regioned_memory.static_find_mixin

**class** angr.storage.memory_mixins.regioned_memory.static_find_mixin.**StaticFindMixin**

Bases: *SmartFindMixin*

Implements data finding for abstract memory.

**find**(*addr*, *data*, *max_search*, ***, *default=None*, *endness=None*, *chunk_size=None*, *max_symbolic_bytes=None*, *condition=None*, *char_size=1*, ***kwargs*)

### angr.storage.memory_mixins.simple_interface_mixin

class angr.storage.memory_mixins.simple_interface_mixin.**SimpleInterfaceMixin**

Bases: *MemoryMixin*

**load**(*addr*, *size=None*, *, *endness=None*, *condition=None*, *fallback=None*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, *, *endness=None*, *condition=None*, ***kwargs*)

### angr.storage.memory_mixins.simplification_mixin

class angr.storage.memory_mixins.simplification_mixin.**SimplificationMixin**

Bases: *MemoryMixin*

**store**(*addr*, *data*, *size=None*, ***kwargs*)

### angr.storage.memory_mixins.size_resolution_mixin

class angr.storage.memory_mixins.size_resolution_mixin.**SizeNormalizationMixin**

Bases: *MemoryMixin*

Provides basic services related to normalizing sizes. After this mixin, sizes will always be a plain int. Assumes that the data is a BV.

- load will throw a TypeError if no size is provided
- store will default to len(data)//byte_width if no size is provided

**load**(*addr*, *size=None*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, ***kwargs*)

class angr.storage.memory_mixins.size_resolution_mixin.**SizeConcretizationMixin**

Bases: *MemoryMixin*

This mixin allows memory to process symbolic sizes. It will not touch any sizes which are not ASTs with non-BVV ops. Assumes that the data is a BV.

- symbolic load sizes will be concretized as their maximum and a warning will be logged
- symbolic store sizes will be dispatched as several conditional stores with concrete sizes

**__init__**(*concretize_symbolic_write_size=False*, *max_concretize_count=256*, *max_symbolic_size=4194304*, *raise_memory_limit_error=False*, *size_limit=257*, ***kwargs*)

**Parameters**

- **concretize_symbolic_write_size** (*bool*)
- **max_concretize_count** (*int | None*)
- **max_symbolic_size** (*int*)
- **raise_memory_limit_error** (*bool*)
- **size_limit** (*int*)

**load**(*addr*, *size=None*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, *, *condition=None*, ***kwargs*)

### angr.storage.memory_mixins.slotted_memory

**class** angr.storage.memory_mixins.slotted_memory.**SlottedMemoryMixin**

Bases: *MemoryMixin*

**__init__**(*width=None*, ***kwargs*)

**load**(*addr*, *size=None*, ***, *endness=None*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, ***, *endness=None*, ***kwargs*)

**changed_bytes**(*other*)

### angr.storage.memory_mixins.smart_find_mixin

**class** angr.storage.memory_mixins.smart_find_mixin.**SmartFindMixin**

Bases: *MemoryMixin*

Memory mixin providing basic searching over concrete and symbolic data.

**find**(*addr*, *data*, *max_search*, ***, *default=None*, *endness=None*, *chunk_size=None*, *max_symbolic_bytes=None*, *condition=None*, *char_size=1*, ***kwargs*)

### angr.storage.memory_mixins.symbolic_merger_mixin

**class** angr.storage.memory_mixins.symbolic_merger_mixin.**SymbolicMergerMixin**

Bases: *MemoryMixin*

### angr.storage.memory_mixins.top_merger_mixin

**class** angr.storage.memory_mixins.top_merger_mixin.**TopMergerMixin**

Bases: *MemoryMixin*

A memory mixin for merging values in memory to TOP.

**__init__**(**args*, *top_func=None*, ***kwargs*)

### angr.storage.memory_mixins.underconstrained_mixin

**class** angr.storage.memory_mixins.underconstrained_mixin.**UnderconstrainedMixin**

Bases: *MemoryMixin*

**__init__**(**args*, ***kwargs*)

**load**(*addr*, *size=None*, ***kwargs*)

**store**(*addr*, *data*, *size=None*, ***kwargs*)

### angr.storage.memory_mixins.unwrapper_mixin

**class** angr.storage.memory_mixins.unwrapper_mixin.**UnwrapperMixin**

Bases: *MemoryMixin*

This mixin processes SimActionObjects by passing on their .ast field.

**store**(*addr*, *data*, *size=None*, ***, *condition=None*, ***kwargs*)

**load**(*addr*, *size=None*, ***, *condition=None*, *fallback=None*, ***kwargs*)

**find**(*addr*, *data*, *max_search*, ***, *default=None*, ***kwargs*)

### 10.46.3 angr.storage.memory_object

angr.storage.memory_object.**obj_bit_size**(*o*)

**class** angr.storage.memory_object.**SimMemoryObject**

Bases: object

A SimMemoryObject is a reference to a byte or several bytes in a specific object in memory. It should be used only by the bottom layer of memory.

**__init__**(*obj*, *base*, *endness*, *length=None*, *byte_width=8*)

**is_bytes**

**base**

**object: BV | FP**

**length**

**endness**

**size**()

**property variables**

**property symbolic**

**property last_addr**

**concrete_bytes**(*offset*, *size*)

**Return type**
bytes | None

**Parameters**

- **offset** (*int*)
- **size** (*int*)

**includes**(*x*)

**bytes_at**(*addr*, *length*, *allow_concrete=False*, *endness='Iend_BE'*)

**class** angr.storage.memory_object.**SimLabeledMemoryObject**

Bases: *SimMemoryObject*

SimLabeledMemoryObject is a SimMemoryObject with a label

**__init__**(*obj*, *base*, *endness*, *length=None*, *byte_width=8*, *label=None*)

**label**

angr.storage.memory_object.**bv_slice**(*value*, *offset*, *size*, *rev*, *bw*)

Extremely cute utility to pretend you've serialized a value to stored bytes, sliced it a la python slicing, and then deserialized those bytes to an integer again.

**Parameters**

- **value** (BV) – The bitvector to slice

- **offset** (int) – The byte offset from the first stored byte to slice from, or a negative offset from the end.
- **size** (int) – The number of bytes to return. If None, return all bytes from the offset to the end. If larger than the number of bytes from the offset to the end, return all bytes from the offset to the end.
- **rev** (bool) – Whether the pretend-serialization should be little-endian
- **bw** (int) – The byte width

**Return type**
BV

**Returns**
The new bitvector

## 10.47 angr.tablespecs

**class** angr.tablespecs.**StringTableSpec**

Bases: object

**__init__**(*byte_width=8*)

**append_args**(*args*, *add_null=True*)

**append_env**(*env*, *add_null=True*)

**add_string**(*string*)

**add_pointer**(*pointer*)

**add_null**()

**dump**(*state*, *end_addr*, *align=16*)

## 10.48 angr.utils

angr.utils.**is_pyinstaller**()

Detect if we are currently running as a PyInstaller-packaged program.

**Return type**
bool

**Returns**
True if we are running as a PyInstaller-packaged program. False if we are running in Python directly (e.g., development mode).

angr.utils.**looks_like_sql**(*s*)

Determine if string *s* looks like an SQL query.

**Parameters**
**s** (str) – The string to detect.

**Return type**
bool

**Returns**
True if the string looks like an SQL, False otherwise.

angr.utils.**timethis**(*func*)

## 10.48.1 angr.utils.ail

**class** angr.utils.ail.**BlockDefs**

Bases: object

Same-block definition maps: VirtualVariable id and Tmp index -> defining expression (last assignment wins).

**__init__**(*statements=()*, *all_defs=None*)

**Parameters**

- **statements** (*Sequence[Statement]*)
- **all_defs** (*GraphVVarDefs | None*)

**vvars:** dict[int, *Expression*]

**tmps:** dict[int, *Expression*]

**stmt_has_call:** dict[int, bool]

**all_defs**

**static of**(*block*, *block_defs=None*)

Return the precomputed defs when the caller passed them, otherwise build them for block.

**Return type**
*BlockDefs*

**Parameters**

- **block** (*Block | None*)
- **block_defs** (*BlockDefs | None*)

**vvar_defs**(*reg_offsets=None*)

VirtualVariable definitions: block-local first, then the unique whole-graph ones (if available), optionally limited to the register vvars at `reg_offsets`.

**Return type**
Mapping[int, *Expression*]

**Parameters**
**reg_offsets** (*frozenset[int] | None*)

**class** angr.utils.ail.**GraphVVarDefs**

Bases: Mapping[int, *Expression*]

VirtualVariable id -> defining expression for the vvars that are defined exactly once in an AIL graph, by something other than a phi. The defining block's Tmps are inlined; definitions that still depend on where they are evaluated (memory loads, calls, leftover Tmps, raw registers) are left out, so every expression returned is valid in any block the vvar is used in. Built on first lookup.

**__init__**(*graph*)

**Parameters**
**graph** (*networkx.DiGraph*)

**register_offset**(*varid*)

**Return type**
int | None

**Parameters**
**varid** (*int*)

**restrict**(*reg_offsets*)

The definitions of the register vvars at the given offsets only.

**Return type**
Mapping[int, *Expression*]

**Parameters**
**reg_offsets** (*frozenset[int]*)

angr.utils.ail.**dirty_has_side_effects**(*expr*)

A dirty helper lifted from a VEX Dirty statement (mfx is set) may write memory or guest state (FLDENV, FSTENV, ...) or observe the outside world (IN, RDTSC): it must survive even when its result is dead, and must neither be duplicated nor moved. Placeholders for unsupported operations and the 80-bit load are pure.

**Return type**
bool

**Parameters**
**expr** (DirtyExpression)

angr.utils.ail.**is_phi_assignment**(*stmt*)

**Return type**
bool

**Parameters**
**stmt** (Statement)

angr.utils.ail.**is_scalar_int_convert**(*expr*)

True for a plain integer width conversion: not lane-wise (vector_count is None) and neither side is floating point. Only these converts admit the usual integer rewrites (folding cascaded conversions, masking, etc.).

**Return type**
bool

**Parameters**
**expr** (Convert)

**class** angr.utils.ail.**HasExprWalker**

Bases: *AILBlockViewer*

Test if any expressions in exprs_to_check is used in another AIL expression.

**__init__**(*exprs_to_check*)

**Parameters**
**exprs_to_check** (*set[Expression]*)

**Return type**
None

**exprs_to_check:** *set[Expression]*

**contains_exprs:** *bool*

angr.utils.ail.**is_head_controlled_loop_block**(*block*)

Determine if the block is a "head-controlled loop." A head-controlled loop (for the lack of a better term) is a single-block that contains a conditional jump towards the beginning of the block. This conditional jump controls whether the loop body (the remaining statements after the conditional jump) will be executed or not. It is usually the result of lifting rep stosX instructions on x86 and amd64.

A head-controlled loop block looks like the following (lifted from rep stosq qword ptr [rdi], rax):

## Block 4036df 00 | 0x4036df | LABEL_4036df: 01 | 0x4036df | vvar_27{reg 72} = @64b [] 02 | 0x4036df | vvar_28{reg 24} = @64b [] 03 | 0x4036df | t1 = rcx<8> 04 | 0x4036df | t4 = (t1 == 0x0<64>) 05 | 0x4036df | if (t4) { Goto 0x4036e2<64> } else { Goto 0x4036df<64> } 06 | 0x4036df | t5 = (t1 - 0x1<64>) 07 | 0x4036df | rcx<8> = t5 08 | 0x4036df | t7 = d<8> 09 | 0x4036df | t6 = (t7 << 0x3<8>) 10 | 0x4036df | t2 = rax<8> 11 |

0x4036df | t3 = rdi<8> 12 | 0x4036df | STORE(addr=t3, data=t2, size=8, endness=Iend_LE, guard=None) 13 | 0x4036df | t8 = (t3 + t6) 14 | 0x4036df | rdi<8> = t8

Where statement 5 is the conditional jump that controls the execution of the remaining statements of this block.

**Parameters**
**block** (Block) – An AIL block.

**Return type**
bool

**Returns**
True if the block represents a head-controlled loop block, False otherwise.

angr.utils.ail.**is_head_controlled_loop_jump**(*block*, *stmt*)

Determine if a conditional jump in the middle of a block controls a head-controlled loop, i.e., it can leave the block. Jumps whose concrete targets all lie inside the block (e.g., libVEX alignment-check exits emitted for AArch64 ldar/stlr) cannot, and the SSA rewriting engine does not record a side-exit state for them.

**Return type**
bool

**Parameters**

- **block** (*Block*)
- **stmt** (ConditionalJump)

angr.utils.ail.**extract_partial_expr**(*base_expr*, *off*, *size*, *ail_manager*, *byte_width=8*)

**Return type**
*Expression*

**Parameters**

- **base_expr** (Expression)
- **off** (*int*)
- **size** (*int*)
- **byte_width** (*int*)

angr.utils.ail.**is_expr_used_as_reg_base_value**(*stmt*, *expr*, *srda*)

Determine if the expression *expr* is used as the base value of an assignment of a full register in *stmt*.

This method returns True if the following conditions hold: - The statement is an assignment to a reg vvar A; - The src of the assignment statement is a bitwise-or expression; - One of the operands of the src expr is the high bits of *expr*; - *expr* is a phi var that relies on reg vvar A.

**Return type**
bool

**Parameters**

- **stmt** (Statement)
- **expr** (Expression)
- **srda** (SRDAModel)

**class** angr.utils.ail.**CallFinder**

Bases: *AILBlockViewer*

Find the first Call statement or expression in a block.

**__init__**(*include_macro=False*)

angr.utils.ail.**find_call**(*obj*, *include_macro=False*)

**Parameters**
**obj** (*Block | Statement | Expression*)

angr.utils.ail.**has_call**(*obj*, *include_macro=False*)

**Parameters**
**obj** (*Block | Statement | Expression*)

angr.utils.ail.**get_terminal_call**(*block*)

**Parameters**
**block** (*Block*)

angr.utils.ail.**unwrap_stack_vvar_reference**(*expr*)

**Return type**
*VirtualVariable* | None

angr.utils.ail.**unwrap_combo_reg_vvar_reference**(*expr*)

**Return type**
*VirtualVariable* | None

angr.utils.ail.**deref_vvar_and_offset**(*expr*)

If expr is a dereference of a VirtualVariable (possibly with an offset), return the VirtualVariable and offset. Otherwise, return (None, None).

**Return type**
tuple[*VirtualVariable*, int] | tuple[None, None]

angr.utils.ail.**extract_vvar_and_offset**(*expr*)

If expr is a VirtualVariable (possibly with an offset), return the VirtualVariable and offset. Otherwise, return (None, None).

**Return type**
tuple[*VirtualVariable*, int] | tuple[None, None]

angr.utils.ail.**unwrap_stack_vvar_reference_with_offset**(*expr*)

**Return type**
tuple[*VirtualVariable*, int] | tuple[None, None]

**class** angr.utils.ail.**CallVisitor**

Bases: *AILBlockViewer*

Visit all Call statements and expressions in a graph, invoking a callback.

**__init__**(*callback*)

**visit**(*graph*)

### 10.48.2 angr.utils.ail_serialization

Typed protobuf pack/parse helpers for AIL-typed containers.

AIL leaves (Block / Statement / Expression) serialize through their native `to_bytes()` methods (postcard, implemented in Rust); the helpers here only encode the Python container structure around them using the typed messages

in angr.protos.ail_types_pb2. There is no generic fallback: any value shape not covered by the schema raises TypeError.

angr.utils.ail_serialization.**simvar_to_bytes_polymorphic**(*v*)

Polymorphic SimVariable encoding: b"<ClassName>\0<proto bytes>".

**Return type**
bytes

**Parameters**
**v** (SimVariable)

angr.utils.ail_serialization.**simvar_from_bytes_polymorphic**(*b*)

**Return type**
*SimVariable*

**Parameters**
**b** (bytes)

**class** angr.utils.ail_serialization.**BlockPool**

Bases: object

A shared pool of Block.to_bytes() payloads for deduplicating byte-identical blocks across graphs.

**__init__**()

**Return type**
None

**payloads:** list[bytes]

**add**(*block*)

**Return type**
int

angr.utils.ail_serialization.**pack_graph**(*graph*, *pool=None*)

Encode a DiGraph of ailment Blocks. Node identity is preserved through per-graph block indices. When pool is given, block payloads are deduplicated into it and the message stores pool refs instead of inline payloads.

**Return type**
AilGraph

**Parameters**

- **graph** (*DiGraph*)
- **pool** (BlockPool | *None*)

angr.utils.ail_serialization.**parse_graph**(*msg*, *pool_payloads=None*)

**Return type**
DiGraph

**Parameters**
**msg** (*AilGraph*)

angr.utils.ail_serialization.**pack_arg_vvars**(*arg_vvars*)

**Return type**
ArgVVars

**Parameters**
**arg_vvars** (*dict[int, tuple[Any, Any]]*)

angr.utils.ail_serialization.**parse_arg_vvars**(*msg*)

**Return type**
dict[int, tuple[Any, Any]]

**Parameters**
**msg** (*ArgVVars*)

angr.utils.ail_serialization.**pack_ite_exprs**(*ite_exprs*)

**Return type**
IteExprs

**Parameters**
**ite_exprs** (*set[tuple[int, Any]]*)

angr.utils.ail_serialization.**parse_ite_exprs**(*msg*)

**Return type**
set[tuple[int, Any]]

**Parameters**
**msg** (*IteExprs*)

angr.utils.ail_serialization.**pack_static_vvars**(*static_vvars*)

**Return type**
StaticVVars

**Parameters**
**static_vvars** (*dict[int, Any]*)

angr.utils.ail_serialization.**parse_static_vvars**(*msg*)

**Return type**
dict[int, Any]

**Parameters**
**msg** (*StaticVVars*)

angr.utils.ail_serialization.**pack_static_buffers**(*static_buffers*)

**Return type**
StaticBuffers

**Parameters**
**static_buffers** (*dict[str, Any]*)

angr.utils.ail_serialization.**parse_static_buffers**(*msg*)

**Return type**
dict[str, Any]

**Parameters**
**msg** (*StaticBuffers*)

### 10.48.3 angr.utils.algo

angr.utils.algo.**binary_insert**(*lst*, *elem*, *key*, *lo=0*, *hi=None*)

Insert an element into a sorted list, and keep the list sorted.

The major difference from bisect.bisect_left is that this function supports a key method, so user doesn't have to create the key array for each insertion.

**Parameters**

- **lst** (list | deque) – The list. Must be pre-ordered.
- **element** – An element to insert into the list.
- **key** (Callable) – A method to get the key for each element in the list.
- **lo** (int) – Lower bound of the search.
- **hi** (int | None) – Upper bound of the search.
- **elem** (*Any*)

**Return type**
None

**Returns**
None

### 10.48.4 angr.utils.balancer

**exception** angr.utils.balancer.**BalancerError**

Bases: *AngrError*

Base class for balancer errors.

**exception** angr.utils.balancer.**BalancerUnsatError**

Bases: *BalancerError*

Exception raised when the balancer determines the constraints are unsatisfiable.

**class** angr.utils.balancer.**Balancer**

Bases: object

The Balancer is an equation redistributor. The idea is to take an AST and rebalance it to, for example, isolate unknown terms on one side of an inequality.

**__init__**(*c*)

**Parameters**
**c** (*Bool*)

**property compat_ret:** tuple[bool, list[tuple[BV, BV]]]

**property replacements:** list[tuple[BV, BV]]

**comparison_info = {'SGE': (False, True, False), 'SGT': (False, False, False), 'SLE': (True, True, False), 'SLT': (True, False, False), 'UGE': (False, True, True), 'UGT': (False, False, True), 'ULE': (True, True, True), 'ULT': (True, False, True)}**

angr.utils.balancer.**constraint_to_si**(*expr*)

Convert a constraint to SI if possible.

**Parameters**
**expr** (Bool)

**Return type**
tuple[bool, list[tuple[BV, BV]]]

**Returns**

### 10.48.5 angr.utils.bits

angr.utils.bits.**truncate_bits**(*value*, *nbits*)

Truncate *value* to *nbits*.

For example: truncate_bits(0x1234, 8) -> 0x34

**Return type**
int

**Parameters**

- **value** (*int*)
- **nbits** (*int*)

angr.utils.bits.**ffs**(*x*)

**Return type**
int

**Parameters**
**x** (*int*)

angr.utils.bits.**sign_extend**(*value*, *bits*)

**Return type**
int

**Parameters**

- **value** (*int*)
- **bits** (*int*)

angr.utils.bits.**zeroextend_on_demand**(*op0*, *op1*)

ZeroExtend op1 if the size of op1 is smaller than the size of op0. Otherwise, return op1.

**Return type**
BV

**Parameters**

- **op0** (*BV*)
- **op1** (*BV*)

angr.utils.bits.**s2u**(*s*, *bits*)

angr.utils.bits.**u2s**(*u*, *bits*)

### 10.48.6 angr.utils.constants

angr.utils.constants.**MAGIC_CONSTANTS = frozenset({195948557, 2343432205, 2880289470, 3131961357, 3135097598, 3405691582, 3405697037, 3735927486, 3735928559, 3735929054, 3735936685, 4207869677, 4276215469, 4277009102})**

Well-known "magic" constants that are universally recognized in hexadecimal.

angr.utils.constants.**is_alignment_mask**(*n*)

angr.utils.constants.**should_use_hex**(*value*, *bits=None*)

Heuristically decide whether an integer constant reads better in hexadecimal than in decimal in decompiled output.

The rules are checked in priority order:

Hexadecimal (returns `True`):

0. Small negative values (`-255 <= value < 0`) are always shown in decimal.
1. The value is a well-known "magic" constant (e.g. `0xdeadbeef`); see *MAGIC_CONSTANTS*, or it is wider than 64 bits (an SSE vector constant).
2. The value is a known alignment mask; see *is_alignment_mask()*.
3. The binary representation contains a run of **>= 8** consecutive 1 bits – typical of sub-word bitmasks (e.g. `0xff`, `0xfff`).
4. The binary representation is a short bit pattern (period 2, 3, 4, or 8) repeated to fill a byte-aligned width – typical of mask/flag constants (e.g. `0x55`/`0xaaaa` for `0101...`, `0x1111`, `0xabab`).
5. The value is a single set bit (power of two) that is **>= 256** – a bit flag (e.g. `0x100`, `0x4000`).

Decimal (returns `False`):

6. The decimal representation of `abs(value)` contains a run of **> 3** (i.e. >= 4) identical digits (e.g. `10000`, `11111`, `1000000`).
7. The value is a nonzero multiple of 1000 – a "round" human-authored decimal number (e.g. `5000`, `20000`).
8. The magnitude is small (`abs(value) <= 9`) – e.g. small loop counters and offsets.

Hexadecimal (weak signal, returns `True`):

9. The low byte is zero and the value is > `0xff` – a "round" hex number (e.g. `0x1200`).
10. The value is a common error code (e.g. `0xc0000005`) in a 32- or 64-bit context.

Otherwise the value is shown in decimal (returns `False`).

**Parameters**

- **value** (`int`) – The integer value to format.
- **bits** (`int | None`) – The bit-width of the value's type. Used to normalize negative values to their unsigned form. If `None`, the value's own bit length is used.

**Return type**
`bool`

**Returns**
`True` if the value should be displayed in hexadecimal, `False` for decimal.

### 10.48.7 angr.utils.cow_interval_map

**type** angr.utils.cow_interval_map.**Segment**[*V*]() = tuple[int, int, V]

**class** angr.utils.cow_interval_map.**IntervalMapCOW**

Bases: Generic[V]

A piecewise-constant map from integers to values, stored as sorted, non-overlapping segments `[start, end) -> value`.

**CHUNK_SIZE: int = 64**

**__init__**(*coalesce_equal=False*)

**Parameters**
**coalesce_equal** (bool) – Merge adjacent segments whose values are equal (==). Otherwise only adjacent segments bound to the very same object are merged. Use it only for immutable values.

**copy**()

**Return type**
*IntervalMapCOW*[V]

**get**[*TD*](*key*, *default=None*)

**Return type**
Union[V, TD]

**Parameters**

- **key** (*int*)
- **default** (*TD*)

**next_key**(*key*)

Return the smallest bound key that is >= *key*, or None.

**Return type**
int | None

**Parameters**
**key** (*int*)

**segment_count**()

**Return type**
int

**segments**()

**Return type**
Iterator[]

**overlapping**(*lo*, *hi*)

Yield (unclipped) segments that overlap [lo, hi), in ascending order.

**Return type**
Iterator[]

**Parameters**

- **lo** (*int*)

- **hi** (*int*)

**unshared_segments**(*other*)

Yield segments of *other* that live in chunks this map does not share. Every other segment of *other* is bound identically in this map.

**Return type**
Iterator[]

**Parameters**
**other** (IntervalMapCOW[V])

**assign**(*lo*, *hi*, *value*)

Bind every key in [lo, hi) to *value*.

**Return type**
None

**Parameters**

- **lo** (*int*)
- **hi** (*int*)
- **value** (*V*)

**pop_range**(*lo*, *hi*)

Unbind every key in [lo, hi) and return the removed bindings, clipped to [lo, hi).

**Return type**
list[]

**Parameters**

- **lo** (*int*)
- **hi** (*int*)

**pop**[*TD*](*key*, **default*)

**Return type**
Union[V, TD]

**Parameters**

- **key** (*int*)
- **default** (*TD*)

### 10.48.8 angr.utils.cowdict

angr.utils.cowdict.**merge_candidate_keys**(*a*, *b*)

Return the keys that may differ between two COW chain maps which (typically) descend from a common ancestor and therefore share a common suffix of layer objects.

A key whose binding lives entirely in the shared suffix – an identical `maps` entry (by identity) that is not shadowed by a deletion in either map – resolves to the same value in both maps, so unioning them is always a no-op and the key is omitted. The result is the union of the keys held in each map's non-shared "head" layers, plus the keys either map has logically deleted: a deleted key may still be bound in the other map's shared suffix and therefore needs to be resurrected by a merge.

**Return type**
set

**Parameters**

- **a** (ChainMapCOW)
- **b** (ChainMapCOW)

class angr.utils.cowdict.**ChainMapCOW**

Bases: ChainMap, Generic[K, V]

Implements a copy-on-write version of ChainMap that supports auto-collapsing.

Tracks logically deleted keys via a _deleted set so that pop() and del work correctly even when keys live in parent maps.

Performance note: We deliberately re-implement the ChainMap walk for better performance. `ChainMap.__getitem__` raises a `KeyError` for every layer that misses, and `ChainMap.get` walks the whole chain twice (`__contains__` and `__getitem__`). We avoid both by inlining `if key in mapping`.

We may revisit the implementation in the future when the performance of ChainMap improves.

**maps**

**dirty**

**collapse_threshold**

**clean**()

**Return type**
*ChainMapCOW*[K, V]

class angr.utils.cowdict.**DefaultChainMapCOW**

Bases: *ChainMapCOW*, Generic[K, V]

Implements a copy-on-write version of ChainMap with default values that supports auto-collapsing.

**default_factory**

**clean**()

**Return type**
*DefaultChainMapCOW*[K, V]

### 10.48.9 angr.utils.cpp

angr.utils.cpp.**is_cpp_funcname_ctor**(*name*)

Check if a demangled C++ function name is a constructor.

**Parameters**
**name** (str) – The demangled C++ function name.

**Return type**
bool

**Returns**
True if the function name is a constructor, False otherwise.

### 10.48.10 angr.utils.doms

class angr.utils.doms.**IncrementalDominators**

Bases: object

This class allows for incrementally updating dominators and post-dominators for graphs. The graph must only be modified by replacing nodes, not adding nodes or edges.

**__init__**(*graph*, *start*, *post=False*)

**Parameters**

- **graph** (*DiGraph*)
- **post** (*bool*)

**init_doms**()

**Return type**
dict[Any, Any]

**init_dfs**()

**Return type**
dict[Any, set[Any]]

**graph_updated**(*new_node*, *replaced_nodes*, *replaced_head*)

**Parameters**

- **new_node** (*Any*)
- **replaced_nodes** (*set[Any]*)
- **replaced_head** (*Any*)

**idom**(*node*)

Get the immediate dominator of a given node.

**Return type**
Any | None

**Parameters**
**node** (*Any*)

**df**(*node*)

Generate the dominance frontier of a node.

**Return type**
set[Any]

**Parameters**
**node** (*Any*)

**dominates**(*dominator_node*, *node*)

Tests if dominator_node dominates (or post-dominates) node.

**Return type**
bool

**Parameters**

- **dominator_node** (*Any*)
- **node** (*Any*)

### 10.48.11 angr.utils.dynamic_dictlist

**class** angr.utils.dynamic_dictlist.**DynamicDictList**

Bases: Generic[VT]

A list-like container class that internally uses dicts to store values when the number of values is less than the threshold *LIST2DICT_THRESHOLD*. Keys must be ints.

The default thresholds are determined according to experiments described at https://github.com/angr/angr/pull/3471#issuecomment-1236515950.

**__init__**(*max_size=None*, *content=None*)

**Parameters**

- **max_size** (*int | None*)
- **content** (*DynamicDictList | dict[int, VT] | list[VT] | None*)

**list_content:** list[VT] | None

**max_size**

**dict_content:** dict[int, VT] | None

**real_length**()

**Return type**
int

### 10.48.12 angr.utils.endness

angr.utils.endness.**ail_const_to_be**(*expr*, *endness*)

**Return type**
*Const*

**Parameters**

- **expr** (*Const*)
- **endness** (*str*)

### 10.48.13 angr.utils.enums_conv

angr.utils.enums_conv.**cfg_jumpkind_to_pb**(*jk*)

angr.utils.enums_conv.**func_edge_type_to_pb**(*jk*)

angr.utils.enums_conv.**cfg_jumpkind_from_pb**(*pb*)

angr.utils.enums_conv.**func_edge_type_from_pb**(*pb*)

### 10.48.14 angr.utils.env

angr.utils.env.**is_pyinstaller**()

Detect if we are currently running as a PyInstaller-packaged program.

**Return type**
bool

**Returns**
True if we are running as a PyInstaller-packaged program. False if we are running in Python directly (e.g., development mode).

### 10.48.15 angr.utils.formatting

angr.utils.formatting.**setup_terminal**()

Check if we are running in a TTY. If so, make sure the terminal supports ANSI escape sequences. If not, disable colorized output. Sets global *ansi_color_enabled* to True if colorized output should be enabled by default.

angr.utils.formatting.**ansi_color**(*s*, *color*)

Colorize string *s* by wrapping in ANSI escape sequence for given *color*.

This function does not consider whether escape sequences are functional or not; it is up to the caller to determine if its appropriate. Check global *ansi_color_enabled* value in this module.

**Return type**
str

**Parameters**

- **s** (*str*)
- **color** (*str | None*)

angr.utils.formatting.**add_edge_to_buffer**(*buf*, *ref*, *start*, *end*, *formatter=None*, *dashed=False*, *ascii_only=None*)

Draw an edge by adding Unicode box and arrow glyphs to beginning of each line in a list of lines.

**Parameters**

- **buf** (Sequence[str]) – Output buffer, used to render formatted edges.
- **ref** (Sequence[str]) – Reference buffer, used to calculate edge depth.
- **start** (int) – Start line.
- **end** (int) – End line, where arrow points.
- **formatter** (Callable[[str], str] | None) – Optional callback function used to format the edge before writing it to output buffer.
- **dashed** (bool) – Render edge line dashed instead of solid.
- **ascii_only** (bool | None) – Render edge using ASCII characters only. If unspecified, guess by stdout encoding.

**Returns**

### 10.48.16 angr.utils.funcid

angr.utils.funcid.**is_function_security_check_cookie**(*func*, *project*, *security_cookie_addr*)

**Return type**
bool

**Parameters**
**security_cookie_addr** (*int*)

angr.utils.funcid.**is_function_security_check_cookie_strict**(*func*, *project*)

**Return type**
tuple[bool, int | None]

**Parameters**
**func** (Function)

angr.utils.funcid.**is_function_security_init_cookie**(*func*, *project*, *security_cookie_addr*)

**Return type**
bool

**Parameters**

- **func** (Function)
- **security_cookie_addr** (*int | None*)

angr.utils.funcid.**is_function_security_init_cookie_win8**(*func*, *project*, *security_cookie_addr*)

**Return type**
bool

**Parameters**

- **func** (Function)
- **security_cookie_addr** (*int*)

angr.utils.funcid.**is_function_likely_security_init_cookie**(*func*)

Conducts a fuzzy match for security_init_cookie function.

**Return type**
bool

**Parameters**
**func** (Function)

### 10.48.17 angr.utils.go_runtime

Identification of Go runtime functions whose control flow CFG recovery cannot infer on its own.

angr has no built-in knowledge of the Go runtime, which gets two families of functions wrong:

- Functions that never return to their call site, chiefly the bounds-check panic stubs emitted at essentially every index expression. Recovered as returning, they attach one dead panic branch per bounds check to every Go function.
- Functions that never execute a `ret` but still resume their caller at the return address: `runtime.morestack` (called from the stack-check trampoline of every non-leaf function) and `runtime.mcall`. Both save the caller's return address in `g.sched` and the scheduler later resumes it with `gogo`. Inferred from their bodies, they look non-returning, which cuts the argument-reload stub after every `morestack` call site off its function and stops recovery of every caller of `runtime.gopark` at the park.

Two identification strategies are provided, because the interesting targets are usually stripped:

- by name, when symbols (or a `.gopclntab`-derived symbol table) are available;
- by shape, which is what actually carries stripped binaries.

A false positive here silently deletes real code, so every shape-based rule below requires either overwhelming corroboration across the binary or an assembly signature that no compiler emits for ordinary code.

angr.utils.go_runtime.**GO_CHECK_PANIC_NAMES**: frozenset[str] =
frozenset({'runtime.goPanicExtendIndex', 'runtime.goPanicExtendIndexU',
'runtime.goPanicExtendSlice3Acap', 'runtime.goPanicExtendSlice3AcapU',
'runtime.goPanicExtendSlice3Alen', 'runtime.goPanicExtendSlice3AlenU',
'runtime.goPanicExtendSlice3B', 'runtime.goPanicExtendSlice3BU',
'runtime.goPanicExtendSlice3C', 'runtime.goPanicExtendSlice3CU',
'runtime.goPanicExtendSliceAcap', 'runtime.goPanicExtendSliceAcapU',
'runtime.goPanicExtendSliceAlen', 'runtime.goPanicExtendSliceAlenU',
'runtime.goPanicExtendSliceB', 'runtime.goPanicExtendSliceBU',
'runtime.goPanicExtendSliceConvert', 'runtime.goPanicIndex', 'runtime.goPanicIndexU',
'runtime.goPanicSlice3Acap', 'runtime.goPanicSlice3AcapU', 'runtime.goPanicSlice3Alen',
'runtime.goPanicSlice3AlenU', 'runtime.goPanicSlice3B', 'runtime.goPanicSlice3BU',
'runtime.goPanicSlice3C', 'runtime.goPanicSlice3CU', 'runtime.goPanicSliceAcap',
'runtime.goPanicSliceAcapU', 'runtime.goPanicSliceAlen', 'runtime.goPanicSliceAlenU',

'runtime.panicunsafestringlen', 'runtime.panicunsafestringlen1',
'runtime.panicunsafestringnilptr', 'runtime.panicunsafestringnilptr1'})

bounds/slice checks (per-kind stubs before go1.25, the `panicBounds` dispatcher after), integer division/shift checks, and the unsafe.Slice/String checks.

**Type**
Panic helpers that only compiler-inserted checks call

angr.utils.go_runtime.**GO_ASSERT_PANIC_NAMES**: frozenset[str] =
frozenset({'runtime.panicdottypeE', 'runtime.panicdottypeI', 'runtime.panicnildottype'})

the check that guards them is the assertion itself.

**Type**
Failure stubs of type assertions (`x.(T)`)

angr.utils.go_runtime.GO_NORETURN_NAMES: frozenset[str] = frozenset({'os.Exit', 'runtime.Goexit', 'runtime.abort', 'runtime.badctxt', 'runtime.badmcall', 'runtime.badmcall2', 'runtime.badreflectcall', 'runtime.execute', 'runtime.exit', 'runtime.exitThread', 'runtime.exitsyscall0', 'runtime.fatal', 'runtime.fatalpanic', 'runtime.fatalthrow', 'runtime.goPanicExtendIndex', 'runtime.goPanicExtendIndexU', 'runtime.goPanicExtendSlice3Acap', 'runtime.goPanicExtendSlice3AcapU', 'runtime.goPanicExtendSlice3Alen', 'runtime.goPanicExtendSlice3AlenU', 'runtime.goPanicExtendSlice3B', 'runtime.goPanicExtendSlice3BU', 'runtime.goPanicExtendSlice3C', 'runtime.goPanicExtendSlice3CU', 'runtime.goPanicExtendSliceAcap', 'runtime.goPanicExtendSliceAcapU', 'runtime.goPanicExtendSliceAlen', 'runtime.goPanicExtendSliceAlenU', 'runtime.goPanicExtendSliceB', 'runtime.goPanicExtendSliceBU', 'runtime.goPanicExtendSliceConvert', 'runtime.goPanicIndex', 'runtime.goPanicIndexU', 'runtime.goPanicSlice3Acap', 'runtime.goPanicSlice3AcapU', 'runtime.goPanicSlice3Alen', 'runtime.goPanicSlice3AlenU', 'runtime.goPanicSlice3B', 'runtime.goPanicSlice3BU', 'runtime.goPanicSlice3C', 'runtime.goPanicSlice3CU', 'runtime.goPanicSliceAcap', 'runtime.goPanicSliceAcapU', 'runtime.goPanicSliceAlen', 'runtime.goPanicSliceAlenU', 'runtime.goPanicSliceB', 'runtime.goPanicSliceBU', 'runtime.goPanicSliceConvert', 'runtime.goexit', 'runtime.goexit0', 'runtime.goexit1', 'runtime.gogo', 'runtime.gopanic', 'runtime.goschedImpl', 'runtime.main', 'runtime.morestackc', 'runtime.panicBounds', 'runtime.panicBounds32', 'runtime.panicBounds32X', 'runtime.panicBounds64', 'runtime.panicExtend', 'runtime.panicExtendIndex', 'runtime.panicExtendIndexU', 'runtime.panicExtendSlice3Acap', 'runtime.panicExtendSlice3AcapU', 'runtime.panicExtendSlice3Alen', 'runtime.panicExtendSlice3AlenU', 'runtime.panicExtendSlice3B', 'runtime.panicExtendSlice3BU', 'runtime.panicExtendSlice3C', 'runtime.panicExtendSlice3CU', 'runtime.panicExtendSliceAcap', 'runtime.panicExtendSliceAcapU', 'runtime.panicExtendSliceAlen', 'runtime.panicExtendSliceAlenU', 'runtime.panicExtendSliceB', 'runtime.panicExtendSliceBU', 'runtime.panicExtendSliceConvert', 'runtime.panicIndex', 'runtime.panicIndexU', 'runtime.panicSlice3Acap', 'runtime.panicSlice3AcapU', 'runtime.panicSlice3Alen', 'runtime.panicSlice3AlenU', 'runtime.panicSlice3B', 'runtime.panicSlice3BU', 'runtime.panicSlice3C', 'runtime.panicSlice3CU', 'runtime.panicSliceAcap', 'runtime.panicSliceAcapU', 'runtime.panicSliceAlen', 'runtime.panicSliceAlenU', 'runtime.panicSliceB', 'runtime.panicSliceBU', 'runtime.panicSliceConvert', 'runtime.panicdivide', 'runtime.panicdottypeE', 'runtime.panicdottypeI', 'runtime.panicfloat', 'runtime.panicmakeslicecap', 'runtime.panicmakeslicelen', 'runtime.panicmem', 'runtime.panicmemAddr', 'runtime.panicnildottype', 'runtime.panicoverflow', 'runtime.panicshift', 'runtime.panicunsafeslicelen', 'runtime.panicunsafeslicelen1', 'runtime.panicunsafeslicenilptr', 'runtime.panicunsafeslicenilptr1', 'runtime.panicunsafestringlen', 'runtime.panicunsafestringnilptr', 'runtime.panicwrap', 'runtime.park_m', 'runtime.schedule', 'runtime.sigpanic', 'runtime.sigpanic0', 'runtime.throw'})

Go runtime (and a few closely related standard library) functions that never transfer control back to the instruction following their call site, checked against the runtime sources of go1.4 to go1.27.

Deliberately excluded because they can fall through to their caller despite the suggestive names: `runtime.mexit` (returns when running on an OS-provided stack, and with it `runtime.mstart0` and `runtime.mstart`), `runtime.badsystemstack`, `runtime.badmorestackg0`, `runtime.badmorestackgsignal` (all only print), `runtime.systemstack`, `runtime.panicCheck1`, `runtime.panicCheck2`, `runtime.startpanic_m`, `runtime.dopanic_m`, and the functions in *GO_RESUMING_NAMES*.

angr.utils.go_runtime.GO_RESUMING_NAMES: frozenset[str] = frozenset({'runtime.mcall', 'runtime.morestack', 'runtime.morestack_noctxt'})

Go runtime functions that never execute a `ret`, but whose callers are resumed at the return address: they save it in `g.sched` and the scheduler later continues there through `gogo`. Their bodies end in calls that do not return (`abort`, `badmcall2`), so they must be marked as returning explicitly.

angr.utils.go_runtime.**GO_STACK_GROWTH_NAMES: frozenset[str] = frozenset({'runtime.morestack', 'runtime.morestack_noctxt', 'runtime.morestackc'})**

`morestack` (and `morestack_noctxt`) grows the stack and resumes the caller after the call, which reloads its arguments and restarts itself; `morestackc` is called instead by //go:systemstack functions and throws.

**Type**
The goroutine stack-growth stubs called from function preambles

angr.utils.go_runtime.**has_go_hint**(*project*)

Cheap test for "this might be a Go binary", to keep the (much more expensive) LanguageDetector off the vast majority of binaries.

**Return type**
bool

**Parameters**
**project** (Project)

angr.utils.go_runtime.**normalize_go_func_name**(*name*)

Strip the ABI wrapper suffix the Go linker appends to duplicated symbols.

**Return type**
str

**Parameters**
**name** (*str*)

angr.utils.go_runtime.**is_go_noreturn_name**(*name*)

**Return type**
bool

**Parameters**
**name** (*str*)

angr.utils.go_runtime.**is_go_resuming_name**(*name*)

**Return type**
bool

**Parameters**
**name** (*str*)

angr.utils.go_runtime.**is_go_stack_growth_name**(*name*)

**Return type**
bool

**Parameters**
**name** (*str*)

**class** angr.utils.go_runtime.**GoRuntimeFunctions**

Bases: object

Go runtime functions identified in a binary, each mapped to a short description of the evidence.

**Variables**

- **noreturn** (dict[int, str]) – Functions that never return to their call site.
- **resuming** (dict[int, str]) – Functions that never execute a `ret` but resume their caller at the return address.
- **stack_growth** (dict[int, str]) – The stack-growth stubs that function preambles call (morestack and morestackc). Each is in `noreturn` or `resuming` as well.

**noreturn:** dict[int, str]

**resuming:** dict[int, str]

**stack_growth:** dict[int, str]

**__init__**(*noreturn=<factory>*, *resuming=<factory>*, *stack_growth=<factory>*)

**Parameters**

- **noreturn** (*dict[int, str]*)
- **resuming** (*dict[int, str]*)
- **stack_growth** (*dict[int, str]*)

**Return type**
None

angr.utils.go_runtime.**find_go_runtime_functions**(*project*, *kb=None*, *use_names=True*)

Identify the Go runtime functions in `project` whose control flow CFG recovery must be told about.

The caller is responsible for having established that this is a Go binary.

**Parameters**

- **use_names** (bool) – Consult symbol names. Set to False to exercise the shape-based path that stripped binaries depend on.
- **project** (Project)

**Return type**
*GoRuntimeFunctions*

angr.utils.go_runtime.**find_go_noreturn_functions**(*project*, *kb=None*, *use_names=True*)

Identify Go runtime functions in `project` that never return. See *find_go_runtime_functions()*.

**Return type**
dict[int, str]

**Returns**
A mapping from function address to a short description of the evidence.

**Parameters**

- **project** (Project)
- **use_names** (*bool*)

### 10.48.18 angr.utils.graph

angr.utils.graph.**shallow_reverse**[*T*](*g*)

Make a shallow copy of a directional graph and reverse the edges. This is a workaround to solve the issue that one cannot easily make a shallow reversed copy of a graph in NetworkX 2, since networkx.reverse(copy=False) now returns a GraphView, and GraphViews are always read-only.

**Parameters**
**g** (networkx.DiGraph[T]) – The graph to reverse.

**Return type**
networkx.DiGraph[T]

**Returns**
A new networkx.DiGraph that has all nodes and all edges of the original graph, with edges reversed.

angr.utils.graph.**inverted_idoms**[*T*](*graph*, *end_node=None*)

Invert the given graph and generate the immediate dominator tree on the inverted graph. This is useful for computing post-dominators.

**Parameters**

- **graph** (networkx.DiGraph[T]) – The graph to invert and generate immediate dominator tree for.
- **end_node** (*T | None*)

**Return type**
tuple[networkx.DiGraph[T], dict[T, T] | None]

**Returns**
A tuple of the inverted graph and the immediate dominator tree.

angr.utils.graph.**to_acyclic_graph**[*T*](*graph*, *node_order=None*, *loop_heads=None*)

Convert a given DiGraph into an acyclic graph.

**Parameters**

- **graph** (networkx.DiGraph[T]) – The graph to convert.
- **ordered_nodes** – A list of nodes sorted in a topological order.
- **loop_heads** (list[T] | None) – A list of known loop head nodes.
- **node_order** (*dict[T, int] | None*)

**Return type**
networkx.DiGraph[T]

**Returns**
The converted acyclic graph.

angr.utils.graph.**dfs_back_edges**[*T*](*graph*, *start_node*, ***, *visit_all_nodes=False*, *visited=None*)

Perform an iterative DFS traversal of the graph, returning back edges.

**Parameters**

- **graph** (networkx.DiGraph[T]) – The graph to traverse.
- **start_node** (T) – The node where to start the traversal.
- **visit_all_nodes** (*bool*)
- **visited** (*set[T] | None*)

**Return type**
Iterator[tuple[T, T]]

**Returns**
An iterator of 'backward' edges.

angr.utils.graph.**subgraph_between_nodes**[*T*](*graph*, *source*, *frontier*, *include_frontier=False*)

For a directed graph, return a subgraph that includes all nodes going from a source node to a target node.

**Parameters**

- **graph** (networkx.DiGraph[T]) – The directed graph.
- **source** (T) – The source node.
- **frontier** (Iterable[T]) – A collection of target nodes.
- **include_frontier** (bool) – Should nodes in frontier be included in the subgraph.

**Returns**
A subgraph.

**Return type**
networkx.DiGraph[T]

angr.utils.graph.**dominates**[*T*](*idom*, *dominator_node*, *node*)

**Return type**
bool

**Parameters**

- **idom** (*dict[T, T]*)
- **dominator_node** (*T*)
- **node** (*T*)

angr.utils.graph.**compute_dominance_intervals**[*T*](*idom*, *head*)

Compute entry/exit (Euler tour) intervals over the dominator tree described by idom, so that dominance queries answer in O(1) via dominates_by_intervals() instead of dominates()'s O(tree depth) chain walk. Only nodes present in idom (i.e., reachable from the head) get an interval.

**Return type**
dict[T, tuple[int, int]]

**Parameters**

- **idom** (*dict[T, T]*)
- **head** (*T*)

angr.utils.graph.**dominates_by_intervals**[*T*](*intervals*, *dominator_node*, *node*)

O(1) equivalent of dominates() over intervals from compute_dominance_intervals(). Node objects must be truthy (all AIL and structurer nodes are), which is the only case where dominates() behaves differently.

**Return type**
bool

**Parameters**

- **intervals** (*dict[T, tuple[int, int]]*)
- **dominator_node** (*T*)
- **node** (*T*)

angr.utils.graph.**compute_dominance_frontier**[*T*](*graph*, *domtree*)

Compute a dominance frontier based on the given post-dominator tree.

This implementation is based on figure 2 of paper An Efficient Method of Computing Static Single Assignment Form by Ron Cytron, etc.

**Parameters**

- **graph** (networkx.DiGraph[T]) – The graph where we want to compute the dominance frontier.
- **domtree** (networkx.DiGraph[T]) – The dominator tree

**Return type**
dict[T, set[T]]

**Returns**
A dict of dominance frontier

class angr.utils.graph.**TemporaryNode**

Bases: object

A temporary node.

Used as the start node and end node in post-dominator tree generation. Also used in some test cases.

**__init__**(*label*)

class angr.utils.graph.**ContainerNode**

Bases: Generic[T]

A container node.

Only used in dominator tree generation. We did this so we can set the index property without modifying the original object.

**__init__**(*obj*)

**Parameters**
**obj** (*T*)

**index: int | None**

**property obj: T**

class angr.utils.graph.**Dominators**

Bases: Generic[T]

Describes dominators in a graph.

**__init__**(*graph*, *entry_node*, *successors_func=None*, *reverse=False*)

**Parameters**

- **graph** (*networkx.DiGraph[T]*)
- **entry_node** (*T*)

**dom: networkx.DiGraph[T]**

class angr.utils.graph.**PostDominators**

Bases: *Dominators*[T], Generic[T]

Describe post-dominators in a graph.

**__init__**(*graph*, *entry_node*, *successors_func=None*)

**Parameters**

- **graph** (*networkx.DiGraph[T]*)

- **entry_node** (*T*)

**property post_dom: networkx.DiGraph[T]**

**class** angr.utils.graph.**SCCPlaceholder**

Bases: object

Describes a placeholder for strongly-connected-components in a graph.

**__init__**(*scc_id*, *addr*)

**scc_id**

**addr**

**class** angr.utils.graph.**GraphUtils**

Bases: object

A helper class with some static methods and algorithms implemented, that in fact, might take more than just normal CFGs.

**static find_merge_points**(*function_addr*, *function_endpoints*, *graph*)

Given a local transition graph of a function, find all merge points inside, and then perform a quasi-topological sort of those merge points.

A merge point might be one of the following cases: - two or more paths come together, and ends at the same address. - end of the current function

**Parameters**

- **function_addr** (*int*) – Address of the function.
- **function_endpoints** (*list*) – Endpoints of the function. They typically come from Function.endpoints.
- **graph** (*networkx.DiGraph*) – A local transition graph of a function. Normally it comes from Function.graph.

**Returns**

A list of ordered addresses of merge points.

**Return type**

list

**static find_widening_points**(*function_addr*, *function_endpoints*, *graph*)

Given a local transition graph of a function, find all widening points inside.

Correctly choosing widening points is very important in order to not lose too much information during static analysis. We mainly consider merge points that has at least one loop back edges coming in as widening points.

**Parameters**

- **function_addr** (*int*) – Address of the function.
- **function_endpoints** (*list*) – Endpoints of the function, typically coming from Function.endpoints.
- **graph** (*networkx.DiGraph*) – A local transition graph of a function, normally Function.graph.

**Returns**

A list of addresses of widening points.

**Return type**
list

**static dfs_postorder_nodes_deterministic**[*T*](*graph*, *source*)

**Return type**
Iterator[T]

**Parameters**

- **graph** (*networkx.DiGraph[T]*)
- **source** (*T*)

**static dfs_postorder_nodes_deterministic_multi**[*T*](*graph*, *sources*)

Deterministic post-order DFS covering multiple source nodes with a single shared `visited` set. Equivalent to `dfs_postorder_nodes_deterministic` over a synthetic super-source connected to every node in `sources` (sources are traversed in `_sort_node` order), but without mutating the graph – so it works directly on a zero-copy overlay view. Use it for multi-entry acyclic graphs.

**Return type**
Iterator[T]

**Parameters**

- **graph** (*networkx.DiGraph[T]*)
- **sources** (*Iterable[T]*)

**static reverse_post_order_sort_nodes**(*graph*, *nodes=None*)

Sort a given set of nodes in reverse post ordering.

**Parameters**

- **graph** (*networkx.DiGraph*) – A local transition graph of a function.
- **nodes** (*iterable*) – A collection of nodes to sort.

**Returns**
A list of sorted nodes.

**Return type**
list

**static sort_node**(*node*)

A sorter to make a deterministic order of nodes. The key is a total order: nodes sharing an address (duplicated blocks) are separated by their idx instead of falling back on insertion order.

**Return type**
tuple[int, int, int, str]

**static sort_edge**(*edge*)

A sorter to make a deterministic order of edges.

**static quasi_topological_sort_nodes**[*T*](*graph*, *nodes=None*, *loop_heads=None*, *panic_mode_threshold=3000*)

Sort a given set of nodes from a graph based on the following rules:

# - if A -> B and not B -> A, then we have A < B # - if A -> B and B -> A, then the ordering is undefined

Following the above rules gives us a quasi-topological sorting of nodes in the graph. It also works for cyclic graphs.

**Parameters**

- **graph** (networkx.DiGraph[T]) – A local transition graph of the function.
- **nodes** (list[T] | None) – A list of nodes to sort. None if you want to sort all nodes inside the graph.
- **loop_heads** (list[T] | None) – A list of nodes that should be treated loop heads.
- **panic_mode_threshold** (int) – Threshold of nodes in an SCC to begin aggressively removing edges.

**Return type**
list[T]

**Returns**
A list of ordered nodes.

**static loop_nesting_forest**(*graph*, *start_node*)

Generates the loop-nesting forest for the provided directional graph. This is *not* the algorithm proposed by Ramalingam.

**Parameters**

- **graph** (DiGraph) – the graph to generate the loop-nesting forest for.
- **start_node** – the node to start traversing the graph from.

**Return type**
OrderedDict[Any, DiGraph]

**Returns**
An ordered dict of loop heads to their corresponding loop nodes.

**class** angr.utils.graph.**LinkedListNode**

Bases: Generic[T]

A node in a linked list.

**__init__**(*v*)

**Parameters**
**v** (*T*)

**v: T**

**next: Optional[*LinkedListNode*[T]]**

**prev: Optional[*LinkedListNode*[T]]**

**class** angr.utils.graph.**DirectedGraphHelper**

Bases: Generic[T]

A helper class for accelerating some graph algorithms on directed graphs.

_node_order keeps a dictionary of nodes and their order in a quasi-topological sort of the region full graph (graph_with_successors). _generate_node_order() initializes this dictionary. we then update this dictionary when new nodes are created.

We do not populate _node_order when working on acyclic graphs because it's not used for acyclic graphs.

With graph_version, _node_order is tagged with the graph version it is valid for, and readers regenerate it once the graph has changed.

__init__(*graph*, *cyclic_graph*, *head*, *graph_version=None*)

**Parameters**

- **graph** (*networkx.DiGraph[T]*)
- **cyclic_graph** (*bool*)
- **head** (*T*)
- **graph_version** (*Callable[[], int] | None*)

node_order_is_current()

**Return type**
bool

resync_node_order(*was_current*)

Call after mirroring a node merge through replace_node(s): an order that was current before the merge still is.

**Return type**
None

**Parameters**
**was_current** (*bool*)

reset()

dfs_postorder_nodes_deterministic(*source*)

Post-order DFS traversal of the directed graph using cache. Avoids acyclic-graph conversion or full-graph traversal when cache is available.

**Return type**
Iterator[T]

**Parameters**
**source** (*T*)

replace_node(*old_node*, *new_node*)

Update cache when a node is replaced in the graph.

**Parameters**

- **old_node** (*T*)
- **new_node** (*T*)

replace_nodes(*old_node_0*, *old_node_1*, *new_node*)

Update cache when multiple nodes are replaced by a single node in the graph.

**Return type**
None

**Parameters**

- **old_node_0** (*T*)
- **old_node_1** (*T*)
- **new_node** (*T*)

**remove_node**(*node*)

Update cache when a node is removed from the graph.

**Parameters**
**node** (*T*)

**add_node_successor**(*node*, *successor*)

**Return type**
None

**Parameters**

- **node** (*T*)
- **successor** (*T*)

**get_node_order**()

**Return type**
dict[T, int]

**to_acyclic_by_order**(*graph*)

**Return type**
networkx.DiGraph[T]

**Parameters**
**graph** (*RegionOverlayGraph[T]*)

**sort_nodes_by_order**(*nodes*)

**Return type**
list[T]

**Parameters**
**nodes** (*list[T]*)

**loop_heads**()

**Return type**
set[T]

### 10.48.19 angr.utils.hashing

angr.utils.hashing.**stable_hash**(*t*)

**Return type**
int

**Parameters**
**t** (*tuple*)

### 10.48.20 angr.utils.ins_addr_list

**class** angr.utils.ins_addr_list.**InsAddrList**

Bases: object

A memory-efficient replacement for list[int] that stores instruction addresses as a base address plus a bytestring of instruction sizes (one byte per instruction).

Address reconstruction: addr[i] = base_addr + sum(ins_sizes[0:i])

For compatibility, this class exposes a list-like interface (iteration, indexing, length, membership testing, concatenation, etc.).

**__init__**(*base_addr=0*, *ins_sizes=b''*)

**Parameters**

- **base_addr** (*int*)
- **ins_sizes** (*bytes | bytearray | list[int]*)

**classmethod from_addr_list**(*addrs*)

Construct an InsAddrList from a list/sequence of absolute instruction addresses.

**Return type**
*InsAddrList*

**property base_addr: int**

**property ins_sizes: bytes**

**extend**(*other*)

**Return type**
None

**Parameters**
**other** (InsAddrList)

**index**(*value*, *start=0*, *stop=None*)

**count**(*value*)

**Return type**
int

**copy**()

**Return type**
*InsAddrList*

### 10.48.21 angr.utils.json_utils

JSON encode/decode wrappers that use msgspec when available (CPython only), falling back to the standard library json module otherwise.

angr.utils.json_utils.**json_decode**(*data*)

**Return type**
Any

**Parameters**
**data** (bytes)

angr.utils.json_utils.**json_encode**(*obj*)

**Return type**
bytes

**Parameters**
**obj** (*Any*)

### 10.48.22 angr.utils.lazy_import

angr.utils.lazy_import.**lazy_import**(*name*)

### 10.48.23 angr.utils.library

angr.utils.library.**get_function_name**(*s*)

Get the function name from a C-style function declaration string.

**Parameters**
**s** (*str*) – A C-style function declaration string.

**Returns**
The function name.

**Return type**
str

angr.utils.library.**register_kernel_types**()

angr.utils.library.**convert_cproto_to_py**(*c_decl*)

Convert a C-style function declaration string to its corresponding SimTypes-based Python representation.

**Parameters**
**c_decl** (*str*) – The C-style function declaration string.

**Return type**
tuple[str, *SimTypeFunction*, str]

**Returns**
A tuple of the function name, the prototype, and a string representing the SimType-based Python representation.

angr.utils.library.**convert_cppproto_to_py**(*cpp_decl*, *with_param_names=False*)

Pre-process a C++-style function declaration string to its corresponding SimTypes-based Python representation.

**Parameters**

- **cpp_decl** (str) – The C++-style function declaration string.
- **with_param_names** (*bool*)

**Return type**
tuple[str | None, *SimTypeCppFunction* | None, str | None]

**Returns**
A tuple of the function name, the prototype, and a string representing the SimType-based Python representation.

angr.utils.library.**parsedcprotos2py**(*parsed_cprotos*, *fd_spots=frozenset({})*, *remove_sys_prefix=False*)

Parse a list of C function declarations and output to Python code that can be embedded into angr.procedures.definitions.

```
>>> # parse the list of glibc C prototypes and output to a file
>>> from angr.procedures.definitions import glibc
>>> with open("glibc_protos", "w") as f: f.write(cprotos2py(glibc._libc_c_decls))
```

**Parameters**
**parsed_cprotos** (list[tuple[str, *SimTypeFunction*, str]]) – A list of tuples where each tuple is (function name, parsed C function prototype, the original function declaration).

**Return type**
str

**Returns**
A Python string.

angr.utils.library.**cprotos2py**(*cprotos*, *fd_spots=frozenset({})*, *remove_sys_prefix=False*)

Parse a list of C function declarations and output to Python code that can be embedded into angr.procedures.definitions.

```
>>> # parse the list of glibc C prototypes and output to a file
>>> from angr.procedures.definitions import glibc
>>> with open("glibc_protos", "w") as f: f.write(cprotos2py(glibc._libc_c_decls))
```

**Parameters**
**cprotos** (list[str]) – A list of C prototype strings.

**Return type**
str

**Returns**
A Python string.

angr.utils.library.**get_cpp_function_name_and_metadata**(*demangled_name*)

Parse a demangled C++ declaration into a function name.

Note that the extracted name may include template instantiation, for example:

example_func<int>

**Parameters**
**demangled_name** (str) – The demangled C++ function name.

**Return type**
tuple[str, dict[str, bool]]

**Returns**
The qualified function name, excluding return type and parameters, and a dictionary with keys indicating if the function is a constructor or a destructor.

angr.utils.library.**get_cpp_function_name**(*demangled_name*)

Parse a demangled C++ declaration into a function name.

Note that the extracted name may include template instantiation, for example:

example_func<int>

**Parameters**
**demangled_name** (str) – The demangled C++ function name.

**Return type**
str

**Returns**
The qualified function name, excluding return type and parameters.

angr.utils.library.**get_rust_function_name**(*demangled_name*)

### 10.48.24 angr.utils.loader

angr.utils.loader.**is_pc**(*project*, *ins_addr*, *addr*)

Check if the given address is program counter (PC) or not. This function is for handling the case on some bizarre architectures where PC is always the currently executed instruction address plus a constant value.

**Parameters**

- **project** (*Project*) – An angr Project instance.
- **ins_addr** (int) – The address of an instruction. We calculate PC using this instruction address.
- **addr** (int) – The address to check against.

**Return type**
bool

**Returns**
True if the given instruction address is the PC, False otherwise.

angr.utils.loader.**is_in_readonly_section**(*project*, *addr*)

Check if the specified address is inside a read-only section.

**Parameters**

- **project** (*Project*) – An angr Project instance.
- **addr** (int) – The address to check.

**Return type**
bool

**Returns**
True if the given address belongs to a read-only section, False otherwise.

angr.utils.loader.**is_in_readonly_segment**(*project*, *addr*)

Check if the specified address is inside a read-only segment.

**Parameters**

- **project** (*Project*) – An angr Project instance.
- **addr** (int) – The address to check.

**Return type**
bool

**Returns**
True if the given address belongs to a read-only segment, False otherwise.

### 10.48.25 angr.utils.mp

**class** angr.utils.mp.**Closure**

Bases: NamedTuple

A pickle-able lambda; note that f, args, and kwargs must be pickleable

**f:** Callable[..., None]

Alias for field number 0

**args:** list[Any]

Alias for field number 1

**kwargs:** *dict[str, Any]*

Alias for field number 2

**static __new__**(*_cls*, *f*, *args*, *kwargs*)

Create new instance of Closure(f, args, kwargs)

**Parameters**

- **f** (*Callable[..., None]*)
- **args** (*list[Any]*)
- **kwargs** (*dict[str, Any]*)

**class** angr.utils.mp.**Initializer**

Bases: object

A singleton class with global state used to initialize a multiprocessing.Process

**classmethod get**()

A wrapper around init since this class is a singleton

**Return type**
*Initializer*

**__init__**(*, *_manual=True*)

**Parameters**
**_manual** (*bool*)

**initializers:** *list[Closure]*

**register**(*f*, **args*, ***kwargs*)

A shortcut for adding Closures as initializers

**Return type**
None

**Parameters**

- **f** (*Callable[[...], None]*)
- **args** (*Any*)
- **kwargs** (*Any*)

**initialize**()

Initialize a multiprocessing.Process Set the current global initializer to the same state as this initializer, then calls each initializer

**Return type**
None

angr.utils.mp.**mp_context**()

angr.utils.mp.**protect_stdio_from_forked_children**()

Make forked worker processes safe to use from a process whose stdin/stdout are a protocol channel.

**Return type**
None

### 10.48.26 angr.utils.orderedset

**class** angr.utils.orderedset.**OrderedSet**

Bases: MutableSet[T], Generic[T]

Adapted from http://code.activestate.com/recipes/576694/ Originally created by Raymond Hettinger and licensed under MIT.

**__init__**(*iterable=None*)

### 10.48.27 angr.utils.smart_cache

**class** angr.utils.smart_cache.**SmartLRUCache**

Bases: LRUCache

An LRU cache that supports an eviction callback.

**__init__**(*maxsize*, *getsizeof=None*, *evict=None*)

**Parameters**
**evict** (*Callable | None*)

### 10.48.28 angr.utils.ssa

**class** angr.utils.ssa.**AILWhitelistExprTypeWalker**

Bases: *AILBlockViewer*

Walks an AIL expression or statement and determines if it is built *only* out of a whitelisted set of expression types. has_nonwhitelisted_exprs is set to True as soon as any expression whose type is not in the whitelist is encountered.

Note that the whitelist must include the operator/container types that the walker recurses through (e.g. BinaryOp, UnaryOp), otherwise those nodes would be flagged as non-whitelisted.

**__init__**(*whitelist_expr_types*)

**Parameters**
**whitelist_expr_types** (*tuple[type, ...]*)

**class** angr.utils.ssa.**VVarUsesCollector**

Bases: *AILBlockViewer*

Collect all uses of virtual variables and their use locations in an AIL block. Skip collecting use locations if block is not specified.

**__init__**()

**vvar_and_uselocs:** dict[int, list[tuple[*VirtualVariable*, *AILCodeLocation*]]]

**vvars:** set[int]

angr.utils.ssa.**check_in_between_stmts**(*graph*, *blocks*, *defloc*, *useloc*, *predicate*)

**Parameters**

- **graph** (*DiGraph*)
- **blocks** (*dict[tuple[int, int], Block]*)
- **defloc** (AILCodeLocation)
- **useloc** (AILCodeLocation)

- **predicate** (*Callable*)

angr.utils.ssa.**clobber_def_ids**(*stmt*)

vvar IDs of the registers that a call statement clobbers and thereby defines. The `clobber_defs` tag holds `(varid, reg_offset, bits)` triples, flattened so that it survives serialization.

**Return type**
list[int]

angr.utils.ssa.**clobber_def_vvars**(*stmt*)

The register virtual variables that a call statement defines by clobbering them (see `clobber_def_ids`).

**Return type**
list[*VirtualVariable*]

angr.utils.ssa.**get_tmp_deflocs**(*blocks*)

**Return type**
dict[, dict[*Tmp*, int]]

**Parameters**
**blocks** (*Iterable[Block]*)

angr.utils.ssa.**get_tmp_uselocs**(*blocks*)

**Return type**
dict[, dict[*Tmp*, set[tuple[*Tmp*, int]]]]

**Parameters**
**blocks** (*Iterable[Block]*)

angr.utils.ssa.**get_vvar_deflocs**(*blocks*, *phi_vvars=None*)

**Return type**
dict[int, tuple[*VirtualVariable*, *AILCodeLocation*]]

**Parameters**
**phi_vvars** (*dict[int, set[int | None]] | None*)

angr.utils.ssa.**get_vvar_uselocs**(*blocks*)

**Return type**
dict[int, list[tuple[*VirtualVariable*, *AILCodeLocation*]]]

angr.utils.ssa.**has_call_in_between_stmts**(*graph*, *blocks*, *defloc*, *useloc*, *skip_if_contains_vvar=None*)

**Return type**
bool

**Parameters**

- **graph** (*DiGraph*)
- **blocks** (*dict[tuple[int, int], Block]*)
- **defloc** (AILCodeLocation)
- **useloc** (AILCodeLocation)
- **skip_if_contains_vvar** (*int | None*)

angr.utils.ssa.**has_ite_expr**(*expr*)

**Return type**
bool

**Parameters**
**expr** (Expression)

angr.utils.ssa.**has_load_expr_in_between_stmts**(*graph*, *blocks*, *defloc*, *useloc*, *skip_if_contains_vvar=None*)

**Return type**
bool

**Parameters**

- **graph** (*DiGraph*)
- **blocks** (*dict[tuple[int, int], Block]*)
- **defloc** (AILCodeLocation)
- **useloc** (AILCodeLocation)
- **skip_if_contains_vvar** (*int | None*)

angr.utils.ssa.**has_store_stmt_in_between_stmts**(*graph*, *blocks*, *defloc*, *useloc*)

**Return type**
bool

**Parameters**

- **graph** (*DiGraph*)
- **blocks** (*dict[tuple[int, int], Block]*)
- **defloc** (AILCodeLocation)
- **useloc** (AILCodeLocation)

angr.utils.ssa.**is_const_and_vvar_assignment**(*stmt*, *walker_cached=None*)

**Return type**
bool

**Parameters**

- **stmt** (Statement)
- **walker_cached** (AILWhitelistExprTypeWalker | *None*)

angr.utils.ssa.**is_const_assignment**(*stmt*, *only_consts=False*)

**Return type**
tuple[bool, *Const* | *StackBaseOffset* | None]

**Parameters**

- **stmt** (Statement)
- **only_consts** (*bool*)

angr.utils.ssa.**is_const_vvar_load_assignment**(*stmt*, *walker_cached=None*)

**Return type**
bool

**Parameters**

- **stmt** (Statement)
- **walker_cached** (AILWhitelistExprTypeWalker | *None*)

angr.utils.ssa.**is_const_vvar_load_dirty_assignment**(*stmt*, *walker_cached=None*)

**Return type**
bool

**Parameters**

- **stmt** (Statement)
- **walker_cached** (AILWhitelistExprTypeWalker | *None*)

angr.utils.ssa.**is_phi_assignment**(*stmt*)

**Return type**
bool

**Parameters**
**stmt** (Statement)

angr.utils.ssa.**is_vvar_eliminatable**(*vvar*, *def_stmt*)

**Return type**
bool

**Parameters**

- **vvar** (VirtualVariable)
- **def_stmt** (Statement | *None*)

angr.utils.ssa.**phi_assignment_get_src**(*stmt*)

**Return type**
*Phi* | None

**Parameters**
**stmt** (Statement)

## Submodules

| *combined_uses_collector* | Combined walker that collects VVar uses + Tmp uses in a single pass. |
| *tmp_uses_collector* | |
| *vvar_extra_defs_collector* | |
| *vvar_uses_collector* | |

### angr.utils.ssa.combined_uses_collector

Combined walker that collects VVar uses + Tmp uses in a single pass.

SPropagator's `_analyze` historically called four separate helpers (`get_vvar_deflocs`, `get_vvar_uselocs`, `get_tmp_deflocs`, `get_tmp_uselocs`) against the same set of blocks. Each of the two `_uselocs` helpers spun up its own `AILBlockViewer` and walked every block independently.

Folding both use-collectors into a single walker halves the walk-the-block cost (one `_handle_expr` dispatch chain per visited node, not two) and is a drop-in replacement: the per-block tmp use extraction matches `TmpUsesCollector`'s shape and the cross-block vvar use accumulator matches `VVarUsesCollector`'s.

**class** angr.utils.ssa.combined_uses_collector.**VVarAndTmpUsesCollector**

Bases: *AILBlockViewer*

Collect VVar uses + Tmp uses in a single pass.

See `VVarUsesCollector` / `TmpUsesCollector` for the per-side semantics. This combined version inherits both:

- `vvar_and_uselocs` accumulates across all blocks walked (consumer extracts when done).
- `tmp_and_uselocs` is intended to be extracted per-block; `reset_tmp_uses_only()` clears just the tmp side without losing the cross-block vvar accumulator.

**__init__**()

**Return type**
None

**reset_tmp_uses_only**()

**Return type**
None

### angr.utils.ssa.tmp_uses_collector

**class** angr.utils.ssa.tmp_uses_collector.**TmpUsesCollector**

Bases: *AILBlockViewer*

Collect all uses of temporary variables and their use statement IDs in an AIL block.

**__init__**()

### angr.utils.ssa.vvar_extra_defs_collector

**class** angr.utils.ssa.vvar_extra_defs_collector.**FindExtraDefs**

Bases: *AILBlockViewer*

Simple walker that finds any extra defs

**__init__**(**args*, ***kwargs*)

### angr.utils.ssa.vvar_uses_collector

**class** angr.utils.ssa.vvar_uses_collector.**VVarUsesCollector**

Bases: *AILBlockViewer*

Collect all uses of virtual variables and their use locations in an AIL block. Skip collecting use locations if block is not specified.

__init__()

vvar_and_uselocs: dict[int, list[tuple[*VirtualVariable*, *AILCodeLocation*]]]

vvars: set[int]

### 10.48.29 angr.utils.strings

angr.utils.strings.**decode_utf16_string**(*data*)

Decode a UTF-16 encoded string from a bytes object in a resilient manner.

**Parameters**

- **data** (bytes) – The bytes object containing the UTF-16 encoded string.
- **errors** – The error handling scheme. Default is 'strict'. Other options include 'ignore', 'replace', etc.

**Return type**
str

**Returns**
The decoded string.

### 10.48.30 angr.utils.tagged_interval_map

**class** angr.utils.tagged_interval_map.**TaggedIntervalMap**

Bases: object

Catalogs features of intervals.

__init__(*nbits=0*)

**Parameters**
**nbits** (int) – Number of binning bits. Higher values reduce detail. 0 for no binning.

**property nbits:** int

**add**(*addr*, *size*, *tags*)

Add interval starting at *addr* of *size* bytes.

When binning, intervals endpoints are aligned to 2^nbits. Gaps between added intervals are populated with implicit intervals having tag value of 0. Overlapping intervals will have tag bits OR'd together.

Adjacent intervals in the interval map have unique tags. When intervals are added to the map, any adjacent stops with identical tags will be eliminated so the map retains this property.

For example: if an interval(addr=0, size=100, tags=1) is added, followed by (100, 100, 1), the resulting interval in the map will be (0, 200, 1).

**Return type**
None

**Parameters**

- **addr** (*int*)
- **size** (*int*)
- **tags** (*int*)

**irange**(*min_addr=None*, *max_addr=None*)

Iterate over intervals intersecting [min_addr, max_addr], yielding interval (addr, size, tags) tuples. Implicit gap intervals (with tags=0) are also returned.

**Parameters**

- **min_addr** (int | None) – Minimum address (inclusive) to begin iterating from. If None, iterate from start of map.
- **max_addr** (int | None) – Maximum address (inclusive) to iterate to. If None, iterate to end of map.

**Return type**
Iterator[tuple[int, int, int]]

### 10.48.31 angr.utils.timing

angr.utils.timing.**print_timing_total**()

angr.utils.timing.**timethis**(*func*)

### 10.48.32 angr.utils.types

angr.utils.types.**unpack_typeref**(*ty*)

angr.utils.types.**unpack_pointer**(*ty*, *iterative=False*)

**Return type**
*SimType* | None

**Parameters**

- **ty** (SimType)
- **iterative** (*bool*)

angr.utils.types.**unpack_pointer_and_array**(*ty*, *iterative=False*)

**Return type**
*SimType* | None

**Parameters**

- **ty** (SimType)
- **iterative** (*bool*)

angr.utils.types.**replace_pointer_pts_to**(*ty*, *old_pts_to*, *new_pts_to*)

**Return type**
*SimTypePointer* | None

**Parameters**

- **ty** (SimType)
- **old_pts_to** (SimType)
- **new_pts_to** (SimType)

angr.utils.types.**unpack_array**(*ty*)

**Return type**
*SimType* | None

angr.utils.types.**squash_array_reference**(*ty*)

angr.utils.types.**dereference_simtype**(*t*, *type_collections*, *memo=None*, *keep_missing=False*, *arch=None*)

Replace every SimTypeRef inside *t* with the real type from *type_collections*.

When arch is not None, memo holds the with_arch() copies of every dereferenced struct and union. This way we can avoid creating duplicate arch-ed copies of the same type.

**Parameters**

- **keep_missing** (bool) – Leave a SimTypeRef in place when no collection defines it, instead of raising AngrMissingTypeError.
- **t** (SimType)
- **type_collections** (*list[SimTypeCollection]*)
- **memo** (*dict[str | int, SimType] | None*)
- **arch** (*Arch | None*)

**Return type**
*SimType*

angr.utils.types.**type_collections_for_lib**(*libname*)

The type collections that prototypes of library *libname* refer to. Falls back to every loaded type collection when the library is unknown or declares no type collections.

**Return type**
list[*SimTypeCollection*]

**Parameters**
**libname** (*str | None*)

angr.utils.types.**dereference_simtype_by_lib**(*t*, *libname*)

**Return type**
*SimType*

**Parameters**

- **t** (SimType)
- **libname** (*str*)

angr.utils.types.**relink_typerefs**(*t*, *typerefs*, *_seen=None*)

Replace every TypeRef inside *t* whose name is in *typerefs* with the TypeRef object from *typerefs*, so that deserialized types share the TypeRef objects owned by a TypesStore again. The TypeRef targets themselves are not descended into; *t* is updated in place.

**Return type**
*SimType*

**Parameters**

- **t** (SimType)
- **typerefs** (*dict[str, TypeRef]*)
- **_seen** (*dict[int, SimType] | None*)

angr.utils.types.**find_type_refs**(*t*, *_seen=None*)

Collect the names of all SimTypeRef nodes reachable from *t*.

**Return type**
set[str]

**Parameters**

- **t** (SimType)
- **_seen** (*set[int] | None*)

angr.utils.types.**make_type_reference**(*t*, *memo=None*, *type_collections=None*)

Take a SimType and convert named SimStruct instances to SimTypeRefs.

**Parameters**

- **t** (*SimType*) – The SimType instance to convert.
- **type_collections** (list[*SimTypeCollection*] | None) – Only structs defined in one of these collections are converted, so that the references can be resolved later. None converts every named struct.
- **memo** (*dict[str, SimTypeRef] | None*)

**Return type**
*SimType*

**Returns**
A converted SimType instance.

### 10.48.33 angr.utils.vex

angr.utils.vex.**get_tmp_def_stmt**(*vex_block*, *tmp_idx*)

**Return type**
int | None

**Parameters**

- **vex_block** (*IRSB*)
- **tmp_idx** (*int*)

angr.utils.vex.**block_branch_ins_addr**(*ins_addrs*, *block_addr*, *block_size*, *arch*)

Determine the address of the control-transfer instruction that ends a block.

On architectures without delay slots, this is the last instruction of the block. On delay-slot architectures (MIPS), the block ends with the delay slot and the branch precedes it; depending on the lifter, the branch and its delay slot are recorded either as two IMarks (libVEX forks before Valgrind 3.27.1, pcode) or as a single IMark spanning both instructions (Valgrind 3.27.1+), in which case the last recorded instruction address is the branch itself.

**Parameters**

- **ins_addrs** (InsAddrSeq) – Instruction addresses of the block (IMark start addresses).
- **block_addr** (int) – Address of the block.
- **block_size** (int | None) – Size of the block in bytes, or None when it is unknown.
- **arch** (Arch) – The architecture.

**Return type**
int | None

**Returns**
The branch instruction address, or None if ins_addrs is empty.

angr.utils.vex.**block_is_single_instruction**(*ins_addrs*, *block_addr*, *block_size*, *arch*)

Determine whether a block holds at most one instruction, i.e. it is too short to carry a branch together with its delay slot. Only libVEX (Valgrind 3.27.1+) merges a branch and its delay slot into one IMark; such an IMark spans two fixed-width instructions, so on libVEX architectures a lone IMark counts as a single instruction only if it is no longer than one instruction.

**Parameters**

- **ins_addrs** (InsAddrSeq) – Instruction addresses of the block (IMark start addresses).
- **block_addr** (int) – Address of the block.
- **block_size** (int) – Size of the block in bytes.
- **arch** (Arch) – The architecture.

**Return type**
bool

**Returns**
True if the block holds at most one instruction.

### 10.48.34 angr.utils.vvar_set

**class** angr.utils.vvar_set.**VVarSet**

Bases: object

A set of non-negative integers (virtual variable IDs) stored as one Python int bitmask.

Liveness sets are wide (thousands of ids) and numerous (two per block), so a hash set costs tens of bytes per element while a bitmask costs one bit. It supports the subset of the set protocol that liveness and its consumers use; mixed operations with real sets are accepted and return the type of the left operand.

**__init__**(*iterable=()*)

**Parameters**
**iterable** (*Iterable[int]*)

**classmethod from_bits**(*bits*)

**Return type**
*VVarSet*

**Parameters**
**bits** (*int*)

**property bits: int**

**add**(*v*)

**Return type**
None

**Parameters**
**v** (*int*)

**discard**(*v*)

**Return type**
None

**Parameters**
**v** (*int*)

**remove**(*v*)

**Return type**
None

**Parameters**
**v** (*int*)

**update**(*other*)

**Return type**
None

**Parameters**
**other** (*Iterable[int]*)

**difference_update**(*other*)

**Return type**
None

**Parameters**
**other** (*Iterable[int]*)

**intersection_update**(*other*)

**Return type**
None

**Parameters**
**other** (*Iterable[int]*)

**clear**()

**Return type**
None

**copy**()

**Return type**
*VVarSet*

**isdisjoint**(*other*)

**Return type**
bool

**Parameters**
**other** (*Iterable[int]*)

**issubset**(*other*)

**Return type**
bool

**Parameters**
**other** (*Iterable[int]*)

**issuperset**(*other*)

**Return type**
bool

**Parameters**
**other** (*Iterable[int]*)

**union**(*other*)

Return self|value.

**Return type**
*VVarSet*

**Parameters**
**other** (*Iterable[int]*)

**intersection**(*other*)

**Return type**
*VVarSet*

**Parameters**
**other** (*Iterable[int]*)

**difference**(*other*)

**Return type**
*VVarSet*

**Parameters**
**other** (*Iterable[int]*)

### 10.48.35 angr.utils.x87

**class** angr.utils.x87.**X87Tracker**

Bases: object

Forward-tracks the x87 stack pointer `ftop` through the statements of one VEX block, together with the tmps derived from it. Values are 32-bit masked; `ftop` becomes None once it cannot be determined.

**__init__**(*irsb*, *ftop*, *ftop_off*, *ftop_size*, *array_bases=()*)

**Parameters**

- **irsb** (*IRSB*)
- **ftop** (*int*)
- **ftop_off** (*int*)
- **ftop_size** (*int*)
- **array_bases** (*tuple[int, ...]*)

**eval**(*expr*)

**Return type**
int | None

**step**(*stmt*)

Process one statement; False once ftop is unknown.

**Return type**
bool

**class** angr.utils.x87.**X87StackModel**

Bases: object

Net effects of functions and calls on the x87 stack pointer `ftop` (0 at a function entry), obtained by forward-tracking `ftop` through VEX blocks. A callee's effect comes from its prototype (an x87 FP return pushes one value) or, failing that, from its own code.

**Variables**
**assume_balanced** – Treat a callee whose effect cannot be determined as leaving the stack balanced.

**__init__**(*project*, *kb*, *callee_deltas=None*, *max_blocks=256*, *max_callee_blocks=256*, *assume_balanced=False*)

**Parameters**

- **project** (Project)
- **kb** (KnowledgeBase)
- **callee_deltas** (*dict[int, int | None] | None*)
- **max_blocks** (*int*)
- **max_callee_blocks** (*int*)
- **assume_balanced** (*bool*)

**static prototype_returns_x87**(*func*)

**Return type**
bool

**Parameters**
**func** (Function)

**static prototype_delta**(*func*)

The net effect on ftop declared by the function's prototype (x87 arguments popped, x87 return pushed).

**Return type**
int | None

**Parameters**
**func** (Function)

**callee_delta**(*callee_addr*)

The callee's net effect on ftop (-1: returns a value on the x87 stack; +1: pops its x87 argument), or None when it cannot be determined.

**Return type**
int | None

**Parameters**
**callee_addr** (*int*)

**function_delta**(*func*, *max_blocks=None*)

The function's net effect on ftop, or None if unknown or path-dependent.

**Return type**
int | None

**Parameters**

- **func** (Function)
- **max_blocks** (*int | None*)

**static classify_x87_args**(*ret_ftops*, *depth*)

Values the function takes on the x87 stack (MSVC _CI* helpers take st(0); _ftol takes and pops st(0)), under the convention that the callee pops all of them, from the result of scan.

**Return type**
tuple[int, bool] | None

**Returns**
The number of x87 arguments and whether the function returns a value in st(0) (in place of its popped arguments), or None when it takes no x87 arguments or its stack effect is inconsistent.

**Parameters**

- **ret_ftops** (*dict[int, int | None] | None*)
- **depth** (*int*)

**ret_ftops**(*func*, *max_blocks=None*)

ftop at each return site of the function (keyed by block address; None where unknown), or None when the function is too large to scan.

**Return type**
dict[int, int | None] | None

**Parameters**

- **func** (Function)
- **max_blocks** (*int | None*)

**scan**(*func*, *max_blocks=None*)

**Return type**
tuple[dict[int, int | None] | None, int]

**Returns**
ftop at each return site (see ret_ftops), and how many x87 slots the function reads that it did not push (values passed on the x87 stack, as by MSVC's _CI* and _ftol helpers).

**Parameters**

- **func** (Function)
- **max_blocks** (*int | None*)

## 10.49 angr.vaults

**class** angr.vaults.**VaultPickler**

Bases: Pickler

**__init__**(*vault*, *file*, **args*, *assigned_objects=()*, ***kwargs*)

A persistence-aware pickler. It will check for persistence of any objects except for those with IDs in 'assigned_objects'.

**persistent_id**(*obj*)

class angr.vaults.**VaultUnpickler**

Bases: Unpickler

**persistent_load**(*pid*)

class angr.vaults.**Vault**

Bases: MutableMapping

The vault is a serializer for angr.

**keys**()

Should return the IDs stored by the vault.

**__init__**()

**is_stored**(*i*)

Checks if the provided id is already in the vault.

**load**(*oid*)

**store**(*o*)

**dumps**(*o*)

Returns a serialized string representing the object, post-deduplication.

**Parameters**
**o** – the object

**loads**(*s*)

Deserializes a string representation of the object.

**Parameters**
**s** – the string

**static close**()

class angr.vaults.**VaultDict**

Bases: *Vault*

A Vault that uses a dictionary for storage.

**__init__**(*d=None*)

class angr.vaults.**VaultDir**

Bases: *Vault*

A Vault that uses a directory for storage.

**__init__**(*d=None*)

class angr.vaults.**VaultShelf**

Bases: *VaultDict*

A Vault that uses a shelve.Shelf for storage.

**__init__**(*path=None*)

**close**()

**class** angr.vaults.**VaultDirShelf**

Bases: *VaultDict*

A Vault that uses a directory for storage, where every object is stored into a single shelve.Shelf instance. VaultDir creates a file for each object. VaultDirShelf creates only one file for a stored object and everything else it references.

**__init__**(*d=None*)

**store**(*o*)

**load**(*oid*)
