Welcome to angr's documentation! This documentation is intended to be a guide for learning angr, as well as a reference for the API. If you're new to angr,

The angr team maintains a number of libraries that are used as part of angr. These libraries are:

- archinfo - Information about CPU architectures
- pyvex - Python bindings to the VEX IR
- pypcode - Python bindings to the Pcode IR
- cle - Many-platform binary loader

angr also has a GUI! Check out angr-management.

CHAPTER

ONE

# INTRODUCTION

angr is a multi-architecture binary analysis toolkit, with the capability to perform dynamic symbolic execution (like Mayhem, KLEE, etc.) and various static analyses on binaries. If you'd like to learn how to use it, you're in the right place!

We've tried to make using angr as pain-free as possible - our goal is to create a user-friendly binary analysis suite, allowing a user to simply start up iPython and easily perform intensive binary analyses with a couple of commands. That being said, binary analysis is complex, which makes angr complex. This documentation is an attempt to help out with that, providing narrative explanation and exploration of angr and its design.

Several challenges must be overcome to programmatically analyze a binary. They are, roughly:

- Loading a binary into the analysis program.
- Translating a binary into an intermediate representation (IR).
- Performing the actual analysis. This could be:
  - A partial or full-program static analysis (i.e., dependency analysis, program slicing).
  - A symbolic exploration of the program's state space (i.e., "Can we execute it until we find an overflow?").
  - Some combination of the above (i.e., "Let's execute only program slices that lead to a memory write, to find an overflow.")

angr has components that meet all of these challenges. This documentation will explain how each component works, and how they can all be used to accomplish your goals.

## 1.1 Getting Support

To get help with angr, you can:

- Chat with us on the angr Discord server
- Open an issue on the appropriate GitHub repository

## 1.2 Citing angr

If you use angr in an academic work, please cite the papers for which it was developed:

```
@article{shoshitaishvili2016state,
  title={SoK: (State of) The Art of War: Offensive Techniques in Binary Analysis},
  author={Shoshitaishvili, Yan and Wang, Ruoyu and Salls, Christopher and Stephens, Nick␣
↪and Polino, Mario and Dutcher, Audrey and Grosen, Jessie and Feng, Siji and Hauser,␣
↪Christophe and Kruegel, Christopher and Vigna, Giovanni},
  booktitle={IEEE Symposium on Security and Privacy},
```

(continues on next page)

(continued from previous page)

```
  year={2016}
}

@article{stephens2016driller,
  title={Driller: Augmenting Fuzzing Through Selective Symbolic Execution},
  author={Stephens, Nick and Grosen, Jessie and Salls, Christopher and Dutcher, Audrey␣
↪and Wang, Ruoyu and Corbetta, Jacopo and Shoshitaishvili, Yan and Kruegel, Christopher␣
↪and Vigna, Giovanni},
  booktitle={NDSS},
  year={2016}
}

@article{shoshitaishvili2015firmalice,
  title={Firmalice - Automatic Detection of Authentication Bypass Vulnerabilities in␣
↪Binary Firmware},

↪Christopher and Vigna, Giovanni},
  booktitle={NDSS},
  year={2015}
}
```

## 1.3 Going further

You can read this paper, explaining some of the internals, algorithms, and used techniques to get a better understanding on what's going on under the hood.

If you enjoy playing CTFs and would like to learn angr in a similar fashion, angr_ctf will be a fun way for you to get familiar with much of the symbolic execution capability of angr. The angr_ctf repo is maintained by @jakespringer.

CHAPTER

TWO

# GETTING STARTED

## 2.1 Installing angr

angr is a library for Python 3.10+, and must be installed into a Python environment before it can be used.

### 2.1.1 Installing from PyPI

angr is published on PyPI, and using this is the easiest and recommended way to install angr. It can be installed angr with pip:

```
pip install angr
```

**Tip**

It is recommended to use an isolated python environment rather than installing angr globally. Doing so reduces dependency conflicts and aids in reproducibility while debugging. Some popular tools that accomplish this include:

- venv
- pipenv
- virtualenv
- virtualenvwrapper
- conda

**Note**

The PyPI distribution includes binary packages for most popular system configurations. If you are using a system that is not supported by the binary packages, you will need to build the C dependencies from source. See the *Installing from Source* section for more information.

### 2.1.2 Installing from Source

angr is a collection of Python packages, each of which is published on GitHub. The easiest way to install angr from source is to use angr-dev.

To set up a development environment manually, first ensure that build dependencies are installed. These consist of python development headers, `make`, a C++ compiler, and a Rust compiler. On Ubuntu, these can be installed with:

```
sudo apt-get install python3-dev build-essential
curl --proto '=https' --tlsv1.2 -sSf https://sh.rustup.rs | sh
```

Then, checkout and install the following packages, in order:

- archinfo
- pyvex (clone with `--recursive`)
- cle
- angr (`pip install` with `--no-build-isolation`)

### 2.1.3 Installing with Docker

The angr team maintains a container image on Docker Hub that includes angr and its dependencies. This image can be pulled with:

```
docker pull angr/angr
```

The image can be run with:

```
docker run -it angr/angr
```

This will start a shell in the container, with angr installed and ready to use.

### 2.1.4 Troubleshooting

#### angr has no attribute Project, or similar

If angr can be imported but the `Project` class is missing, it is likely one of two problems:

1. There is a script named `angr.py` in the working directory. Rename it to something else.
2. There is a folder called `angr` in your working directory, possibly the cloned repository. Change the working directory to somewhere else.

#### AttributeError: 'module' object has no attribute 'KS_ARCH_X86'

The `keystone` package is installed, which conflicts with the `keystone-engine` package, an optional dependency of angr. Uninstall `keystone` and install `keystone-engine`.

## 2.2 Reporting Bugs

If you've found something that angr isn't able to solve and appears to be a bug, please let us know!

1. Create a fork off of angr/binaries and angr/angr
2. Give us a pull request with angr/binaries, with the binaries in question
3. Give us a pull request for angr/angr, with testcases that trigger the binaries in `angr/tests/broken_x.py`, `angr/tests/broken_y.py`, etc

Please try to follow the testcase format that we have (so the code is in a test_blah function), that way we can very easily merge that and make the scripts run.

An example is:

```
def test_some_broken_feature():
    p = angr.Project("some_binary")
    result = p.analyses.SomethingThatDoesNotWork()
    assert result == "what it should *actually* be if it worked"

if __name__ == '__main__':
    test_some_broken_feature()
```

This will *greatly* help us recreate your bug and fix it faster.

The ideal situation is that, when the bug is fixed, your testcases passes (i.e., the assert at the end does not raise an AssertionError).

Then, we can just fix the bug and rename `broken_x.py` to `test_x.py` and the testcase will run in our internal CI at every push, ensuring that we do not break this feature again.

## 2.3 Developing angr

These are some guidelines so that we can keep the codebase in good shape!

### 2.3.1 pre-commit

Many angr repos contain pre-commit hooks provided by pre-commit. Installing this is as easy as `pip install pre-commit`. After `git` cloning an angr repository, if the repo contains a `.pre-commit-config.yaml`, run `pre-commit install`. Future `git` commits will now invoke these hooks automatically.

### 2.3.2 Coding style

We format our code with black and otherwise try to get as close as the PEP8 code convention as is reasonable without being dumb. If you use Vim, the python-mode plugin does all you need. You can also manually configure vim to adopt this behavior.

Most importantly, please consider the following when writing code as part of angr:

- Try to use attribute access (see the `@property` decorator) instead of getters and setters wherever you can. This isn't Java, and attributes enable tab completion in iPython. That being said, be reasonable: attributes should be fast. A rule of thumb is that if something could require a constraint solve, it should not be an attribute.
- Use our pylintrc from the angr-dev repo. It's fairly permissive, but our CI server will fail your builds if pylint complains under those settings.
- DO NOT, under ANY circumstances, `raise Exception` or `assert False`. **Use the right exception type**. If there isn't a correct exception type, subclass the core exception of the module that you're working in (i.e., `AngrError` in angr, `SimError` in SimuVEX, etc) and raise that. We catch, and properly handle, the right types of errors in the right places, but `AssertionError` and `Exception` are not handled anywhere and force-terminate analyses.
- Avoid tabs; use space indentation instead. Even though it's wrong, the de facto standard is 4 spaces. It is a good idea to adopt this from the beginning, as merging code that mixes both tab and space indentation is awful.
- Avoid super long lines. It's okay to have longer lines, but keep in mind that long lines are harder to read and should be avoided. Let's try to stick to **120 characters**.
- Avoid extremely long functions, it is often better to break them up into smaller functions.
- Always use _ instead of __ for private members (so that we can access them when debugging). *You* might not think that anyone has a need to call a given function, but trust us, you're wrong.

- Format your code with `black`; config is already defined within `pyproject.toml`.

### 2.3.3 Documentation

Document your code. Every *class definition* and *public function definition* should have some description of:

- What it does.
- What are the type and the meaning of the parameters.
- What it returns.

Class docstrings will be enforced by our linter. Do *not* under any circumstances write a docstring which doesn't provide more information than the name of the class. What you should try to write is a description of the environment that the class should be used in. If the class should not be instantiated by end-users, write a description of where it will be generated and how instances can be acquired. If the class should be instantiated by end-users, explain what kind of object it represents at its core, what behavior is expected of its parameters, and how to safely manage objects of its type.

We use Sphinx to generate the API documentation. Sphinx supports docstrings written in ReStructured Text with special keywords to document function and class parameters, return values, return types, members, etc.

Here is an example of function documentation. Ideally the parameter descriptions should be aligned vertically to make the docstrings as readable as possible.

```
def prune(self, filter_func=None, from_stash=None, to_stash=None):
    """
    Prune unsatisfiable paths from a stash.

    :param filter_func: Only prune paths that match this filter.
    :param from_stash:  Prune paths from this stash. (default: 'active')
    :param to_stash:    Put pruned paths in this stash. (default: 'pruned')
    :returns:           The resulting PathGroup.
    :rtype:             PathGroup
    """
```

This format has the advantage that the function parameters are clearly identified in the generated documentation. However, it can make the documentation repetitive, in some cases a textual description can be more readable. Pick the format you feel is more appropriate for the functions or classes you are documenting.

```
def read_bytes(self, addr, n):
   """
   Read `n` bytes at address `addr` in memory and return an array of bytes.
   """
```

### 2.3.4 Unit tests

If you're pushing a new feature and it is not accompanied by a test case it **will be broken** in very short order. Please write test cases for your stuff.

We have an internal CI server to run tests to check functionality and regression on each commit. In order to have our server run your tests, write your tests in a format acceptable to nosetests in a file matching `test_*.py` in the `tests` folder of the appropriate repository. A test file can contain any number of functions of the form `def test_*():` or classes of the form `class Test*(unittest.TestCase):`. Each of them will be run as a test, and if they raise any exceptions or assertions, the test fails. Do not use the `nose.tools.assert_*` functions, as we are presently trying to migrate to `nose2`. Use `assert` statements with descriptive messages or the `unittest.TestCase` assert methods.

Look at the existing tests for examples. Many of them use an alternate format where the `test_*` function is actually a generator that yields tuples of functions to call and their arguments, for easy parametrization of tests.

Finally, do not add docstrings to your test functions.

## 2.4 Help Wanted

**Todo**

This page is woefully out of date. We need to update it.

angr is a huge project, and it's hard to keep up. Here, we list some big TODO items that we would love community contributions for in the hope that it can direct community involvement. They (will) have a wide range of complexity, and there should be something for all skill levels!

We tag issues on our github repositories that would be good for community involvement as "Help wanted". To see the exhaustive list of these, use this github search!

### 2.4.1 Documentation

There are many parts of angr that suffer from little or no documentation. We desperately need community help in this area.

#### API

We are always behind on documentation. We've created several tracking issues on github to understand what's still missing:

1. angr
2. cle
3. pyvex

#### GitBook

This book is missing some core areas. Specifically, the following could be improved:

1. Finish some of the TODOs floating around the book.
2. Organize the Examples page in some way that makes sense. Right now, most of the examples are very redundant. It might be cool to have a simple table of most of them so that the page is not so overwhelming.

#### angr course

Developing a "course" of sorts to get people started with angr would be really beneficial. Steps have already been made in this direction here, but more expansion would be beneficial.

Ideally, the course would have a hands-on component, of increasing difficulty, that would require people to use more and more of angr's capabilities.

### 2.4.2 Research re-implementation

Unfortunately, not everyone bases their research on angr ;-). Until that's remedied, we'll need to periodically implement related work, on top of angr, to make it reusable within the scope of the framework. This section lists some of this related work that's ripe for reimplementation in angr.

#### Redundant State Detection for Dynamic Symbolic Execution

Bugrara, et al. describe a method to identify and trim redundant states, increasing the speed of symbolic execution by up to 50 times and coverage by 4%. This would be great to have in angr, as an ExplorationTechnique. The paper is here: http://nsl.cs.columbia.edu/projects/minestrone/papers/atc13-bugrara.pdf

#### In-Vivo Multi-Path Analysis of Software Systems

Rather than developing symbolic summaries for every system call, we can use a technique proposed by S2E for concretizing necessary data and dispatching them to the OS itself. This would make angr applicable to a *much* larger set of binaries than it can currently analyze.

While this would be most useful for system calls, once it is implemented, it could be trivially applied to any location of code (i.e., library functions). By carefully choosing which library functions are handled like this, we can greatly increase angr's scalability.

### 2.4.3 Development

We have several projects in mind that primarily require development effort.

#### angr-management

The angr GUI, angr-management, could use your improvements! Exposing more of angr's capabilities in a usable way, graphically, would be really useful!

#### IDA Plugins

Much of angr's functionality could be exposed via IDA. For example, angr's data dependence graph could be exposed in IDA through annotations, or obfuscated values can be resolved using symbolic execution.

#### Additional architectures

More architecture support would make angr all the more useful. Supporting a new architecture with angr would involve:

1. Adding the architecture information to archinfo
2. Adding an IR translation. This may be either an extension to PyVEX, producing IRSBs, or another IR entirely.
3. If your IR is not VEX, add a `SimEngine` to support it.
4. Adding a calling convention (`angr.SimCC`) to support SimProcedures (including system calls)
5. Adding or modifying an `angr.SimOS` to support initialization activities.
6. Creating a CLE backend to load binaries, or extending the CLE ELF backend to know about the new architecture if the binary format is ELF.

**ideas for new architectures:**

- PIC, AVR, other embedded architectures
- SPARC (there is some preliminary libVEX support for SPARC here)

**ideas for new IRs:**

- LLVM IR (with this, we can extend angr from just a Binary Analysis Framework to a Program Analysis Framework and expand its capabilities in other ways!)
- SOOT (there is no reason that angr can't analyze Java code, although doing so would require some extensions to our memory model)

#### Environment support

We use the concept of "function summaries" in angr to model the environment of operating systems (i.e., the effects of their system calls) and library functions. Extending this would be greatly helpful in increasing angr's utility. These function summaries can be found here.

A specific subset of this is system calls. Even more than library function SimProcedures (without which angr can always execute the actual function), we have very few workarounds for missing system calls. Every implemented system call extends the set of binaries that angr can handle.

### 2.4.4 Design Problems

There are some outstanding design challenges regarding the integration of additional functionalities into angr.

#### Type annotation and type information usage

angr has fledgling support for types, in the sense that it can parse them out of header files. However, those types are not well exposed to do anything useful with. Improving this support would make it possible to, for example, annotate certain memory regions with certain type information and interact with them intelligently. Consider, for example, interacting with a linked list like this: `print state.mem[state.regs.rax].llist.next.next.value`.

(editor's note: you can actually already do this)

### 2.4.5 Research Challenges

Historically, angr has progressed in the course of research into novel areas of program analysis. Here, we list several self-contained research projects that can be tackled.

#### Semantic function identification/diffing

Current function diffing techniques (TODO: some examples) have drawbacks. For the CGC, we created a semantic-based binary identification engine ( https://github.com/angr/identifier) that can identify functions based on testcases. There are two areas of improvement, each of which is its own research project:

1. Currently, the testcases used by this component are human-generated. However, symbolic execution can be used to automatically generate testcases that can be used to recognize instances of a given function in other binaries.
2. By creating testcases that achieve a "high-enough" code coverage of a given function, we can detect changes in functionality by applying the set of testcases to another implementation of the same function and analyzing changes in code coverage. This can then be used as a semantic function diff.

#### Applying AFL's path selection criteria to symbolic execution

AFL does an excellent job in identifying "unique" paths during fuzzing by tracking the control flow transitions taken by every path. This same metric can be applied to symbolic exploration, and would probably do a depressingly good job, considering how simple it is.

### 2.4.6 Overarching Research Directions

There are areas of program analysis that are not well explored. We list general directions of research here, but readers should keep in mind that these directions likely describe potential undertakings of entire PhD dissertations.

#### Process interactions

Almost all work in the field of binary analysis deals with single binaries, but this is often unrealistic in the real world. For example, the type of input that can be passed to a CGI program depend on pre-processing by a web server. Currently, there is no way to support the analysis of multiple concurrent processes in angr, and many open questions in the field (i.e., how to model concurrent actions).

### Intra-process concurrency

Similar to the modeling of interactions between processes, little work has been done in understanding the interaction of concurrent threads in the same process. Currently, angr has no way to reason about this, and it is unclear from the theoretical perspective how to approach this.

A subset of this problem is the analysis of signal handlers (or hardware interrupts). Each signal handler can be modeled as a thread that can be executed at any time that a signal can be triggered. Understanding when it is meaningful to analyze these handlers is an open problem. One system that does reason about the effect of interrupts is FIE.

### Path explosion

Many approaches (such as Veritesting) attempt to mitigate the path explosion problem in symbolic execution. However, despite these efforts, path explosion is still *the* main problem preventing symbolic execution from being mainstream.

angr provides an excellent base to implement new techniques to control path explosion. Most approaches can be easily implemented as `ExplorationTechnique` s and quickly evaluated (for example, on the CGC dataset).

CHAPTER

THREE

# CORE CONCEPTS

## 3.1 Core Concepts

To get started with angr, you'll need to have a basic overview of some fundamental angr concepts and how to construct some basic angr objects. We'll go over this by examining what's directly available to you after you've loaded a binary!

Your first action with angr will always be to load a binary into a *project*. We'll use `/bin/true` for these examples.

```
>>> import angr
>>> proj = angr.Project('/bin/true')
```

A project is your control base in angr. With it, you will be able to dispatch analyses and simulations on the executable you just loaded. Almost every single object you work with in angr will depend on the existence of a project in some form.

**Tip**

Using and exploring angr in IPython (or other Python command line interpreters) is a main use case that we design angr for. When you are not sure what interfaces are available, tab completion is your friend!

Sometimes tab completion in IPython can be slow. We find the following workaround helpful without degrading the validity of completion results:

```
# Drop this file in IPython profile's startup directory to avoid running it every time.
import IPython
py = IPython.get_ipython()
py.Completer.use_jedi = False
```

### 3.1.1 Basic properties

First, we have some basic properties about the project: its CPU architecture, its filename, and the address of its entry point.

```
>>> import monkeyhex # this will format numerical results in hexadecimal
>>> proj.arch
<Arch AMD64 (LE)>
>>> proj.entry
0x401670
>>> proj.filename
'/bin/true'
```

- *arch* is an instance of an `archinfo.Arch` object for whichever architecture the program is compiled, in this case little-endian amd64. It contains a ton of clerical data about the CPU it runs on, which you can peruse at your leisure. The common ones you care about are `arch.bits`, `arch.bytes` (that one is a `@property` declaration on the main Arch class), `arch.name`, and `arch.memory_endness`.
- *entry* is the entry point of the binary!
- *filename* is the absolute filename of the binary. Riveting stuff!

### 3.1.2 Loading

Getting from a binary file to its representation in a virtual address space is pretty complicated! We have a module called CLE to handle that. CLE's result, called the loader, is available in the `.loader` property. We'll get into detail on how to use this *soon*, but for now just know that you can use it to see the shared libraries that angr loaded alongside your program and perform basic queries about the loaded address space.

```
>>> proj.loader
<Loaded true, maps [0x400000:0x5004000]>

>>> proj.loader.shared_objects # may look a little different for you!
{'ld-linux-x86-64.so.2': <ELF Object ld-2.24.so, maps [0x2000000:0x2227167]>,
 'libc.so.6': <ELF Object libc-2.24.so, maps [0x1000000:0x13c699f]>}

>>> proj.loader.min_addr
0x400000
>>> proj.loader.max_addr
0x5004000

>>> proj.loader.main_object  # we've loaded several binaries into this project. Here's␣
↪the main one!
<ELF Object true, maps [0x400000:0x60721f]>

>>> proj.loader.main_object.execstack  # sample query: does this binary have an␣
↪executable stack?
False
>>> proj.loader.main_object.pic  # sample query: is this binary position-independent?
True
```

### 3.1.3 The factory

There are a lot of classes in angr, and most of them require a project to be instantiated. Instead of making you pass around the project everywhere, we provide `project.factory`, which has several convenient constructors for common objects you'll want to use frequently.

This section will also serve as an introduction to several basic angr concepts. Strap in!

#### Blocks

First, we have `project.factory.block()`, which is used to extract a basic block of code from a given address. This is an important fact - *angr analyzes code in units of basic blocks.* You will get back a Block object, which can tell you lots of fun things about the block of code:

```
>>> block = proj.factory.block(proj.entry) # lift a block of code from the program's␣
↪entry point
<Block for 0x401670, 42 bytes>
```

(continues on next page)

(continued from previous page)

```
>>> block.pp()                          # pretty-print a disassembly to stdout
0x401670:       xor     ebp, ebp
0x401672:       mov     r9, rdx
0x401675:       pop     rsi
0x401676:       mov     rdx, rsp
0x401679:       and     rsp, 0xfffffffffffffff0
0x40167d:       push    rax
0x40167e:       push    rsp
0x40167f:       lea     r8, [rip + 0x2e2a]
0x401686:       lea     rcx, [rip + 0x2db3]
0x40168d:       lea     rdi, [rip - 0xd4]
0x401694:       call    qword ptr [rip + 0x205866]

>>> block.instructions                  # how many instructions are there?
0xb
>>> block.instruction_addrs             # what are the addresses of the instructions?
[0x401670, 0x401672, 0x401675, 0x401676, 0x401679, 0x40167d, 0x40167e, 0x40167f,␣
↪0x401686, 0x40168d, 0x401694]
```

Additionally, you can use a Block object to get other representations of the block of code:

```
>>> block.capstone                       # capstone disassembly
<CapstoneBlock for 0x401670>
>>> block.vex                            # VEX IRSB (that's a Python internal address,␣
↪not a program address)
<pyvex.block.IRSB at 0x7706330>
```

### States

Here's another fact about angr - the `Project` object only represents an "initialization image" for the program. When you're performing execution with angr, you are working with a specific object representing a *simulated program state* - a `SimState`. Let's grab one right now!

```
>>> state = proj.factory.entry_state()
<SimState @ 0x401670>
```

A SimState contains a program's memory, registers, filesystem data... any "live data" that can be changed by execution has a home in the state. We'll cover how to interact with states in depth later, but for now, let's use `state.regs` and `state.mem` to access the registers and memory of this state:

```
>>> state.regs.rip        # get the current instruction pointer
<BV64 0x401670>
>>> state.regs.rax
<BV64 0x1c>
>>> state.mem[proj.entry].int.resolved  # interpret the memory at the entry point as a C␣
↪int
<BV32 0x8949ed31>
```

Those aren't Python ints! Those are *bitvectors*. Python integers don't have the same semantics as words on a CPU, e.g. wrapping on overflow, so we work with bitvectors, which you can think of as an integer as represented by a series of bits, to represent CPU data in angr. Note that each bitvector has a `.length` property describing how wide it is in bits.

We'll learn all about how to work with them soon, but for now, here's how to convert from Python ints to bitvectors and back again:

```
>>> bv = angr.claripy.BVV(0x1234, 32)        # create a 32-bit-wide bitvector with value
↪0x1234
<BV32 0x1234>                                # BVV stands for bitvector value
>>> state.solver.eval(bv)                  # convert to Python int
0x1234
```

You can store these bitvectors back to registers and memory, or you can directly store a Python integer and it'll be converted to a bitvector of the appropriate size:

```
>>> state.regs.rsi = angr.claripy.BVV(3, 64)
>>> state.regs.rsi
<BV64 0x3>

>>> state.mem[0x1000].long = 4
>>> state.mem[0x1000].long.resolved
<BV64 0x4>
```

The `mem` interface is a little confusing at first, since it's using some pretty hefty Python magic. The short version of how to use it is:

- Use array[index] notation to specify an address
- Use `.<type>` to specify that the memory should be interpreted as `type` (common values: char, short, int, long, size_t, uint8_t, uint16_t...)
- From there, you can either:
  - Store a value to it, either a bitvector or a Python int
  - Use `.resolved` to get the value as a bitvector
  - Use `.concrete` to get the value as a Python int

There are more advanced usages that will be covered later!

Finally, if you try reading some more registers you may encounter a very strange looking value:

```
>>> state.regs.rdi
<BV64 reg_48_11_64{UNINITIALIZED}>
```

This is still a 64-bit bitvector, but it doesn't contain a numerical value. Instead, it has a name! This is called a *symbolic variable* and it is the underpinning of symbolic execution. Don't panic! We will discuss all of this in detail exactly two chapters from now.

### Simulation Managers

If a state lets us represent a program at a given point in time, there must be a way to get it to the *next* point in time. A simulation manager is the primary interface in angr for performing execution, simulation, whatever you want to call it, with states. As a brief introduction, let's show how to tick that state we created earlier forward a few basic blocks.

First, we create the simulation manager we're going to be using. The constructor can take a state or a list of states.

```
>>> simgr = proj.factory.simulation_manager(state)
<SimulationManager with 1 active>
>>> simgr.active
[<SimState @ 0x401670>]
```

A simulation manager can contain several *stashes* of states. The default stash, `active`, is initialized with the state we passed in. We could look at `simgr.active[0]` to look at our state some more, if we haven't had enough!

Now... get ready, we're going to do some execution.

```
>>> simgr.step()
```

We've just performed a basic block's worth of symbolic execution! We can look at the active stash again, noticing that it's been updated, and furthermore, that it has **not** modified our original state. SimState objects are treated as immutable by execution - you can safely use a single state as a "base" for multiple rounds of execution.

```
>>> simgr.active
[<SimState @ 0x1020300>]
>>> simgr.active[0].regs.rip                # new and exciting!
<BV64 0x1020300>
>>> state.regs.rip                          # still the same!
<BV64 0x401670>
```

`/bin/true` isn't a very good example for describing how to do interesting things with symbolic execution, so we'll stop here for now.

### 3.1.4 Analyses

angr comes pre-packaged with several built-in analyses that you can use to extract some fun kinds of information from a program. Here they are:

```
>>> proj.analyses.            # Press TAB here in ipython to get an autocomplete-listing␣
↪of everything:
 proj.analyses.BackwardSlice        proj.analyses.CongruencyCheck      proj.analyses.
↪reload_analyses
 proj.analyses.BinaryOptimizer      proj.analyses.DDG                  proj.analyses.
↪StaticHooker
 proj.analyses.BinDiff              proj.analyses.DFG                  proj.analyses.
↪VariableRecovery
 proj.analyses.BoyScout             proj.analyses.Disassembly          proj.analyses.
↪VariableRecoveryFast
 proj.analyses.CDG                  proj.analyses.GirlScout            proj.analyses.
↪Veritesting
 proj.analyses.CFG                  proj.analyses.Identifier           proj.analyses.VFG
 proj.analyses.CFGEmulated          proj.analyses.LoopFinder           proj.analyses.VSA_
↪DDG
 proj.analyses.CFGFast              proj.analyses.Reassembler
```

A couple of these are documented later in this book, but in general, if you want to find how to use a given analysis, you should look in the api documentation for *angr.analyses*. As an extremely brief example: here's how you construct and use a quick control-flow graph:

```
# Originally, when we loaded this binary it also loaded all its dependencies into the␣
↪same virtual address  space
# This is undesirable for most analysis.
>>> proj = angr.Project('/bin/true', auto_load_libs=False)
>>> cfg = proj.analyses.CFGFast()
<CFGFast Analysis Result at 0x2d85130>

# cfg.graph is a networkx DiGraph full of CFGNode instances
```

(continues on next page)

(continued from previous page)

```
# You should go look up the networkx APIs to learn how to use this!
>>> cfg.graph
<networkx.classes.digraph.DiGraph at 0x2da43a0>
>>> len(cfg.graph.nodes())
951

# To get the CFGNode for a given address, use cfg.model.get_any_node
>>> entry_node = cfg.model.get_any_node(proj.entry)
>>> len(list(cfg.graph.successors(entry_node)))
2
```

### 3.1.5 Now what?

Having read this page, you should now be acquainted with several important angr concepts: basic blocks, states, bitvectors, simulation managers, and analyses. You can't really do anything interesting besides just use angr as a glorified debugger, though! Keep reading, and you will unlock deeper powers...

## 3.2 Loading a Binary

Previously, you saw just the barest taste of angr's loading facilities - you loaded `/bin/true`, and then loaded it again without its shared libraries. You also saw `proj.loader` and a few things it could do. Now, we'll dive into the nuances of these interfaces and the things they can tell you.

We briefly mentioned angr's binary loading component, CLE. CLE stands for "CLE Loads Everything", and is responsible for taking a binary (and any libraries that it depends on) and presenting it to the rest of angr in a way that is easy to work with.

### 3.2.1 The Loader

Let's load `examples/fauxware/fauxware` and take a deeper look at how to interact with the loader.

```
>>> import angr, monkeyhex
>>> proj = angr.Project('examples/fauxware/fauxware')
>>> proj.loader
<Loaded fauxware, maps [0x400000:0x5008000]>
```

#### Loaded Objects

The CLE loader (`cle.Loader`) represents an entire conglomerate of loaded *binary objects*, loaded and mapped into a single memory space. Each binary object is loaded by a loader backend that can handle its filetype (a subclass of `cle.Backend`). For example, `cle.ELF` is used to load ELF binaries.

There will also be objects in memory that don't correspond to any loaded binary. For example, an object used to provide thread-local storage support, and an externs object used to provide unresolved symbols.

You can get the full list of objects that CLE has loaded with `loader.all_objects`, as well as several more targeted classifications:

```
# All loaded objects
>>> proj.loader.all_objects
[<ELF Object fauxware, maps [0x400000:0x60105f]>,
 <ELF Object libc-2.23.so, maps [0x1000000:0x13c999f]>,
 <ELF Object ld-2.23.so, maps [0x2000000:0x2227167]>,
```

(continues on next page)

(continued from previous page)

```
 <ELFTLSObject Object cle##tls, maps [0x3000000:0x3015010]>,
 <ExternObject Object cle##externs, maps [0x4000000:0x4008000]>,
 <KernelObject Object cle##kernel, maps [0x5000000:0x5008000]>]

# This is the "main" object, the one that you directly specified when loading the project
>>> proj.loader.main_object
<ELF Object fauxware, maps [0x400000:0x60105f]>

# This is a dictionary mapping from shared object name to object
>>> proj.loader.shared_objects
{ 'fauxware': <ELF Object fauxware, maps [0x400000:0x60105f]>,
  'libc.so.6': <ELF Object libc-2.23.so, maps [0x1000000:0x13c999f]>,
  'ld-linux-x86-64.so.2': <ELF Object ld-2.23.so, maps [0x2000000:0x2227167]> }

# Here's all the objects that were loaded from ELF files
# If this were a windows program we'd use all_pe_objects!
>>> proj.loader.all_elf_objects
[<ELF Object fauxware, maps [0x400000:0x60105f]>,
 <ELF Object libc-2.23.so, maps [0x1000000:0x13c999f]>,
 <ELF Object ld-2.23.so, maps [0x2000000:0x2227167]>]

# Here's the "externs object", which we use to provide addresses for unresolved imports␣
↪and angr internals
>>> proj.loader.extern_object
<ExternObject Object cle##externs, maps [0x4000000:0x4008000]>

# This object is used to provide addresses for emulated syscalls
>>> proj.loader.kernel_object
<KernelObject Object cle##kernel, maps [0x5000000:0x5008000]>

# Finally, you can to get a reference to an object given an address in it
>>> proj.loader.find_object_containing(0x400000)
<ELF Object fauxware, maps [0x400000:0x60105f]>
```

You can interact directly with these objects to extract metadata from them:

```
>>> obj = proj.loader.main_object

# The entry point of the object
>>> obj.entry
0x400580

>>> obj.min_addr, obj.max_addr
(0x400000, 0x60105f)

# Retrieve this ELF's segments and sections
>>> obj.segments
<Regions: [<ELFSegment memsize=0xa74, filesize=0xa74, vaddr=0x400000, flags=0x5,␣
↪offset=0x0>,
           <ELFSegment memsize=0x238, filesize=0x228, vaddr=0x600e28, flags=0x6,␣
↪offset=0xe28>]>
>>> obj.sections
```

(continues on next page)

(continued from previous page)

```
<Regions: [<Unnamed | offset 0x0, vaddr 0x0, size 0x0>,
           <.interp | offset 0x238, vaddr 0x400238, size 0x1c>,
           <.note.ABI-tag | offset 0x254, vaddr 0x400254, size 0x20>,
            ...etc

# You can get an individual segment or section by an address it contains:
>>> obj.find_segment_containing(obj.entry)
<ELFSegment memsize=0xa74, filesize=0xa74, vaddr=0x400000, flags=0x5, offset=0x0>
>>> obj.find_section_containing(obj.entry)
<.text | offset 0x580, vaddr 0x400580, size 0x338>

# Get the address of the PLT stub for a symbol
>>> addr = obj.plt['strcmp']
>>> addr
0x400550
>>> obj.reverse_plt[addr]
'strcmp'

# Show the prelinked base of the object and the location it was actually mapped into␣
↪memory by CLE
>>> obj.linked_base
0x400000
>>> obj.mapped_base
0x400000
```

### Symbols and Relocations

You can also work with symbols while using CLE. A symbol is a fundamental concept in the world of executable formats, effectively mapping a name to an address.

The easiest way to get a symbol from CLE is to use `loader.find_symbol`, which takes either a name or an address and returns a Symbol object.

```
>>> strcmp = proj.loader.find_symbol('strcmp')
>>> strcmp
<Symbol "strcmp" in libc.so.6 at 0x1089cd0>
```

The most useful attributes on a symbol are its name, its owner, and its address, but the "address" of a symbol can be ambiguous. The Symbol object has three ways of reporting its address:

- `.rebased_addr` is its address in the global address space. This is what is shown in the print output.
- `.linked_addr` is its address relative to the prelinked base of the binary. This is the address reported in, for example, `readelf(1)`.
- `.relative_addr` is its address relative to the object base. This is known in the literature (particularly the Windows literature) as an RVA (relative virtual address).

```
>>> strcmp.name
'strcmp'

>>> strcmp.owner
<ELF Object libc-2.23.so, maps [0x1000000:0x13c999f]>
```

(continues on next page)

(continued from previous page)

```
>>> strcmp.rebased_addr
0x1089cd0
>>> strcmp.linked_addr
0x89cd0
>>> strcmp.relative_addr
0x89cd0
```

In addition to providing debug information, symbols also support the notion of dynamic linking. libc provides the strcmp symbol as an export, and the main binary depends on it. If we ask CLE to give us a strcmp symbol from the main object directly, it'll tell us that this is an *import symbol*. Import symbols do not have meaningful addresses associated with them, but they do provide a reference to the symbol that was used to resolve them, as `.resolvedby`.

```
>>> strcmp.is_export
True
>>> strcmp.is_import
False

# On Loader, the method is find_symbol because it performs a search operation to find␣
↪the symbol.
# On an individual object, the method is get_symbol because there can only be one symbol␣
↪with a given name.
>>> main_strcmp = proj.loader.main_object.get_symbol('strcmp')
>>> main_strcmp
<Symbol "strcmp" in fauxware (import)>
>>> main_strcmp.is_export
False
>>> main_strcmp.is_import
True
>>> main_strcmp.resolvedby
<Symbol "strcmp" in libc.so.6 at 0x1089cd0>
```

The specific ways that the links between imports and exports should be registered in memory are handled by another notion called *relocations*. A relocation says, "when you match *[import]* up with an export symbol, please write the export's address to *[location]*, formatted as *[format]*." We can see the full list of relocations for an object (as `Relocation` instances) as `obj.relocs`, or just a mapping from symbol name to Relocation as `obj.imports`. There is no corresponding list of export symbols.

A relocation's corresponding import symbol can be accessed as `.symbol`. The address the relocation will write to is accessible through any of the address identifiers you can use for Symbol, and you can get a reference to the object requesting the relocation with `.owner` as well.

```
# Relocations don't have a good pretty-printing, so those addresses are Python-internal,␣
↪unrelated to our program
>>> proj.loader.shared_objects['libc.so.6'].imports
{'__libc_enable_secure': <cle.backends.elf.relocation.amd64.R_X86_64_GLOB_DAT at␣
↪0x7ff5c5fce780>,
 '__tls_get_addr': <cle.backends.elf.relocation.amd64.R_X86_64_JUMP_SLOT at␣
↪0x7ff5c6018358>,
 '_dl_argv': <cle.backends.elf.relocation.amd64.R_X86_64_GLOB_DAT at 0x7ff5c5fd2e48>,
 '_dl_find_dso_for_object': <cle.backends.elf.relocation.amd64.R_X86_64_JUMP_SLOT at␣
↪0x7ff5c6018588>,
 '_dl_starting_up': <cle.backends.elf.relocation.amd64.R_X86_64_GLOB_DAT at␣
↪0x7ff5c5fd2550>,
```

(continues on next page)

(continued from previous page)

```
 '_rtld_global': <cle.backends.elf.relocation.amd64.R_X86_64_GLOB_DAT at 0x7ff5c5fce4e0>,
 '_rtld_global_ro': <cle.backends.elf.relocation.amd64.R_X86_64_GLOB_DAT at␣
↪0x7ff5c5fcea20>}
```

If an import cannot be resolved to any export, for example, because a shared library could not be found, CLE will automatically update the externs object (`loader.extern_obj`) to claim it provides the symbol as an export.

### 3.2.2 Loading Options

If you are loading something with `angr.Project` and you want to pass an option to the `cle.Loader` instance that Project implicitly creates, you can just pass the keyword argument directly to the Project constructor, and it will be passed on to CLE. You should look at the CLE API docs. if you want to know everything that could possibly be passed in as an option, but we will go over some important and frequently used options here.

#### Basic Options

We've discussed `auto_load_libs` already - it enables or disables CLE's attempt to automatically resolve shared library dependencies, and is off by default. Additionally, there is the opposite, `except_missing_libs`, which, if set to true, will cause an exception to be thrown whenever a binary has a shared library dependency that cannot be resolved.

You can pass a list of strings to `force_load_libs` and anything listed will be treated as an unresolved shared library dependency right out of the gate, or you can pass a list of strings to `skip_libs` to prevent any library of that name from being resolved as a dependency. Additionally, you can pass a list of strings (or a single string) to `ld_path`, which will be used as an additional search path for shared libraries, before any of the defaults: the same directory as the loaded program, the current working directory, and your system libraries.

#### Per-Binary Options

If you want to specify some options that only apply to a specific binary object, CLE will let you do that too. The parameters `main_opts` and `lib_opts` do this by taking dictionaries of options. `main_opts` is a mapping from option names to option values, while `lib_opts` is a mapping from library name to dictionaries mapping option names to option values.

The options that you can use vary from backend to backend, but some common ones are:

- `backend` - which backend to use, as either a class or a name
- `base_addr` - a base address to use
- `entry_point` - an entry point to use
- `arch` - the name of an architecture to use

Example:

```
>>> angr.Project('examples/fauxware/fauxware', main_opts={'backend': 'blob', 'arch':
↪'i386'}, lib_opts={'libc.so.6': {'backend': 'elf'}})
<Project examples/fauxware/fauxware>
```

#### Backends

CLE currently has backends for statically loading ELF, PE, CGC, Mach-O and ELF core dump files, as well as loading files into a flat address space. CLE will automatically detect the correct backend to use in most cases, so you shouldn't need to specify which backend you're using unless you're doing some pretty weird stuff.

You can force CLE to use a specific backend for an object by including a key in its options dictionary, as described above. Some backends cannot autodetect which architecture to use and *must* have a `arch` specified. The key doesn't

need to match any list of architectures; angr will identify which architecture you mean given almost any common identifier for any supported arch.

To refer to a backend, use the name from this table:

| backend name | description | requires `arch`? |
|---|---|---|
| elf | Static loader for ELF files based on PyELFTools | no |
| pe | Static loader for PE files based on PEFile | no |
| mach-o | Static loader for Mach-O files. Does not support dynamic linking or rebasing. | no |
| cgc | Static loader for Cyber Grand Challenge binaries | no |
| backedcgc | Static loader for CGC binaries that allows specifying memory and register backers | no |
| elfcore | Static loader for ELF core dumps | no |
| blob | Loads the file into memory as a flat image | yes |

### 3.2.3 Symbolic Function Summaries

By default, Project tries to replace external calls to library functions by using symbolic summaries termed *SimProcedures* - effectively just Python functions that imitate the library function's effect on the state. We've implemented a whole bunch of functions as SimProcedures. These builtin procedures are available in the `angr.SIM_PROCEDURES` dictionary, which is two-leveled, keyed first on the package name (libc, posix, win32, stubs) and then on the name of the library function. Executing a SimProcedure instead of the actual library function that gets loaded from your system makes analysis a LOT more tractable, at the cost of *some potential inaccuracies*.

When no such summary is available for a given function:

- if `auto_load_libs` is `True`, then the *real* library function is executed instead. This may or may not be what you want, depending on the actual function. For example, some of libc's functions are extremely complex to analyze and will most likely cause an explosion of the number of states for the path trying to execute them.
- if `auto_load_libs` is `False` (this is the default), then external functions are unresolved, and Project will resolve them to a generic "stub" SimProcedure called `ReturnUnconstrained`. It does what its name says: it returns a unique unconstrained symbolic value each time it is called.
- if `use_sim_procedures` (this is a parameter to `angr.Project`, not `cle.Loader`) is `False` (it is `True` by default), then only symbols provided by the extern object will be replaced with SimProcedures, and they will be replaced by a stub `ReturnUnconstrained`, which does nothing but return a symbolic value.
- you may specify specific symbols to exclude from being replaced with SimProcedures with the parameters to `angr.Project`: `exclude_sim_procedures_list` and `exclude_sim_procedures_func`.
- Look at the code for `angr.Project._register_object` for the exact algorithm.

#### Hooking

The mechanism by which angr replaces library code with a Python summary is called hooking, and you can do it too! When performing simulation, at every step angr checks if the current address has been hooked, and if so, runs the hook instead of the binary code at that address. The API to let you do this is `proj.hook(addr, hook)`, where `hook` is a SimProcedure instance. You can manage your project's hooks with `.is_hooked`, `.unhook`, and `.hooked_by`, which should hopefully not require explanation.

There is an alternate API for hooking an address that lets you specify your own off-the-cuff function to use as a hook, by using `proj.hook(addr)` as a function decorator. If you do this, you can also optionally specify a `length` keyword argument to make execution jump some number of bytes forward after your hook finishes.

```
>>> stub_func = angr.SIM_PROCEDURES['stubs']['ReturnUnconstrained'] # this is a CLASS
>>> proj.hook(0x10000, stub_func())  # hook with an instance of the class

>>> proj.is_hooked(0x10000)            # these functions should be pretty self-
↪explanitory
True
>>> proj.hooked_by(0x10000)
<ReturnUnconstrained>
>>> proj.unhook(0x10000)

>>> @proj.hook(0x20000, length=5)
... def my_hook(state):
...     state.regs.rax = 1

>>> proj.is_hooked(0x20000)
True
```

Furthermore, you can use `proj.hook_symbol(name, hook)`, providing the name of a symbol as the first argument, to hook the address where the symbol lives. One very important usage of this is to extend the behavior of angr's built-in library SimProcedures. Since these library functions are just classes, you can subclass them, overriding pieces of their behavior, and then use your subclass in a hook.

### 3.2.4 So far so good!

By now, you should have a reasonable understanding of how to control the environment in which your analysis happens, on the level of the CLE loader and the angr Project. You should also understand that angr makes a reasonable attempt to simplify its analysis by hooking complex library functions with SimProcedures that summarize the effects of the functions.

In order to see all the things you can do with the CLE loader and its backends, look at the CLE API docs.

## 3.3 Symbolic Expressions and Constraint Solving

angr's power comes not from it being an emulator, but from being able to execute with what we call *symbolic variables*. Instead of saying that a variable has a *concrete* numerical value, we can say that it holds a *symbol*, effectively just a name. Then, performing arithmetic operations with that variable will yield a tree of operations (termed an *abstract syntax tree* or *AST*, from compiler theory). ASTs can be translated into constraints for an *SMT solver*, like z3, in order to ask questions like *"given the output of this sequence of operations, what must the input have been?"* Here, you'll learn how to use angr to answer this.

### 3.3.1 Working with Bitvectors

Let's get a dummy project and state so we can start playing with numbers.

```
>>> import angr, monkeyhex
>>> from angr import claripy
>>> proj = angr.Project('/bin/true')
>>> state = proj.factory.entry_state()
```

A bitvector is just a sequence of bits, interpreted with the semantics of a bounded integer for arithmetic. Let's make a few.

```
# 64-bit bitvectors with concrete values 1 and 100
>>> one = claripy.BVV(1, 64)
>>> one
 <BV64 0x1>
>>> one_hundred =claripy.BVV(100, 64)
>>> one_hundred
 <BV64 0x64>

# create a 27-bit bitvector with concrete value 9
>>> weird_nine = claripy.BVV(9, 27)
>>> weird_nine
<BV27 0x9>
```

As you can see, you can have any sequence of bits and call them a bitvector. You can do math with them too:

```
>>> one + one_hundred
<BV64 0x65>

# You can provide normal Python integers and they will be coerced to the
appropriate type: >>> one_hundred + 0x100 <BV64 0x164>

# The semantics of normal wrapping arithmetic apply
>>> one_hundred - one*200
<BV64 0xffffffffffffff9c>
```

You *cannot* say `one + weird_nine`, though. It is a type error to perform an operation on bitvectors of differing lengths. You can, however, extend `weird_nine` so it has an appropriate number of bits:

```
>>> weird_nine.zero_extend(64 - 27)
<BV64 0x9>
>>> one + weird_nine.zero_extend(64 - 27)
<BV64 0xa>
```

`zero_extend` will pad the bitvector on the left with the given number of zero bits. You can also use `sign_extend` to pad with a duplicate of the highest bit, preserving the value of the bitvector under two's complement signed integer semantics.

Now, let's introduce some symbols into the mix.

```
# Create a bitvector symbol named "x" of length 64 bits
>>> x = claripy.BVS("x", 64)
>>> x
<BV64 x_9_64>
>>> y = claripy.BVS("y", 64)
>>> y
<BV64 y_10_64>
```

`x` and `y` are now *symbolic variables*, which are kind of like the variables you learned to work with in 7th grade algebra. Notice that the name you provided has been mangled by appending an incrementing counter and You can do as much arithmetic as you want with them, but you won't get a number back, you'll get an AST instead.

```
>>> x + one
<BV64 x_9_64 + 0x1>
```

(continues on next page)

(continued from previous page)

```
>>> (x + one) / 2
<BV64 (x_9_64 + 0x1) / 0x2>

>>> x - y
<BV64 x_9_64 - y_10_64>
```

Technically `x` and `y` and even `one` are also ASTs - any bitvector is a tree of operations, even if that tree is only one layer deep. To understand this, let's learn how to process ASTs.

Each AST has a `.op` and a `.args`. The op is a string naming the operation being performed, and the args are the values the operation takes as input. Unless the op is `BVV` or `BVS` (or a few others...), the args are all other ASTs, the tree eventually terminating with BVVs or BVSs.

```
>>> tree = (x + 1) / (y + 2)
>>> tree
<BV64 (x_9_64 + 0x1) / (y_10_64 + 0x2)>
>>> tree.op
'__floordiv__'
>>> tree.args
(<BV64 x_9_64 + 0x1>, <BV64 y_10_64 + 0x2>)
>>> tree.args[0].op
'__add__'
>>> tree.args[0].args
(<BV64 x_9_64>, <BV64 0x1>)
>>> tree.args[0].args[1].op
'BVV'
>>> tree.args[0].args[1].args
(1, 64)
```

From here on out, we will use the word "bitvector" to refer to any AST whose topmost operation produces a bitvector. There can be other data types represented through ASTs, including floating point numbers and, as we're about to see, booleans.

### 3.3.2 Symbolic Constraints

Performing comparison operations between any two similarly-typed ASTs will yield another AST - not a bitvector, but now a symbolic boolean.

```
>>> x == 1
<Bool x_9_64 == 0x1>
>>> x == one
<Bool x_9_64 == 0x1>
>>> x > 2
<Bool x_9_64 > 0x2>
>>> x + y == one_hundred + 5
<Bool (x_9_64 + y_10_64) == 0x69>
>>> one_hundred > 5
<Bool True>
>>> one_hundred > -5
<Bool False>
```

One tidbit you can see from this is that the comparisons are unsigned by default. The -5 in the last example is coerced to `<BV64 0xfffffffffffffffb>`, which is definitely not less than one hundred. If you want the comparison to be

signed, you can say `one_hundred.SGT(-5)` (that's "signed greater-than"). A full list of operations can be found at the end of this chapter.

This snippet also illustrates an important point about working with angr - you should never directly use a comparison between variables in the condition for an if- or while-statement, since the answer might not have a concrete truth value. Even if there is a concrete truth value, `if one > one_hundred` will raise an exception. Instead, you should use `solver.is_true` and `solver.is_false`, which test for concrete truthyness/falsiness without performing a constraint solve.

```
>>> yes = one == 1
>>> no = one == 2
>>> maybe = x == y
>>> state.solver.is_true(yes)
True
>>> state.solver.is_false(yes)
False
>>> state.solver.is_true(no)
False
>>> state.solver.is_false(no)
True
>>> state.solver.is_true(maybe)
False
>>> state.solver.is_false(maybe)
False
```

### 3.3.3 Constraint Solving

You can treat any symbolic boolean as an assertion about the valid values of a symbolic variable by adding it as a *constraint* to the state. You can then query for a valid value of a symbolic variable by asking for an evaluation of a symbolic expression.

An example will probably be more clear than an explanation here:

```
>>> state.solver.add(x > y)
>>> state.solver.add(y > 2)
>>> state.solver.add(10 > x)
>>> state.solver.eval(x)
4
```

By adding these constraints to the state, we've forced the constraint solver to consider them as assertions that must be satisfied about any values it returns. If you run this code, you might get a different value for x, but that value will definitely be greater than 3 (since y must be greater than 2 and x must be greater than y) and less than 10. Furthermore, if you then say `state.solver.eval(y)`, you'll get a value of y which is consistent with the value of x that you got. If you don't add any constraints between two queries, the results will be consistent with each other.

From here, it's easy to see how to do the task we proposed at the beginning of the chapter - finding the input that produced a given output.

```
# get a fresh state without constraints
>>> state = proj.factory.entry_state()
>>> input = claripy.BVS('input', 64)
>>> operation = (((input + 4) * 3) >> 1) + input
>>> output = 200
>>> state.solver.add(operation == output)
```

(continues on next page)

(continued from previous page)

```
>>> state.solver.eval(input)
0x3333333333333381
```

Note that, again, this solution only works because of the bitvector semantics. If we were operating over the domain of integers, there would be no solutions!

If we add conflicting or contradictory constraints, such that there are no values that can be assigned to the variables such that the constraints are satisfied, the state becomes *unsatisfiable*, or unsat, and queries against it will raise an exception. You can check the satisfiability of a state with `state.satisfiable()`.

```
>>> state.solver.add(input < 2**32)
>>> state.satisfiable()
False
```

You can also evaluate more complex expressions, not just single variables.

```
# fresh state
>>> state = proj.factory.entry_state()
>>> state.solver.add(x - y >= 4)
>>> state.solver.add(y > 0)
>>> state.solver.eval(x)
5
>>> state.solver.eval(y)
1
>>> state.solver.eval(x + y)
6
```

From this we can see that `eval` is a general purpose method to convert any bitvector into a Python primitive while respecting the integrity of the state. This is why we use `eval` to convert from concrete bitvectors to Python ints, too!

Also note that the x and y variables can be used in this new state despite having been created using an old state. Variables are not tied to any one state, and can exist freely.

### 3.3.4 Floating point numbers

z3 has support for the theory of IEEE754 floating point numbers, and so angr can use them as well. The main difference is that instead of a width, a floating point number has a *sort*. You can create floating point symbols and values with `FPV` and `FPS`.

```
# fresh state
>>> state = proj.factory.entry_state()
>>> a = claripy.FPV(3.2, claripy.fp.FSORT_DOUBLE)
>>> a
<FP64 FPV(3.2, DOUBLE)>

>>> b = claripy.FPS('b', claripy.fp.FSORT_DOUBLE)
>>> b
<FP64 FPS('FP_b_0_64', DOUBLE)>

>>> a + b
<FP64 fpAdd('RNE', FPV(3.2, DOUBLE), FPS('FP_b_0_64', DOUBLE))>

>>> a + 4.4
<FP64 FPV(7.6000000000000005, DOUBLE)>
```

(continues on next page)

(continued from previous page)

```
>>> b + 2 < 0
<Bool fpLT(fpAdd('RNE', FPS('FP_b_0_64', DOUBLE), FPV(2.0, DOUBLE)), FPV(0.0, DOUBLE))>
```

So there's a bit to unpack here - for starters the pretty-printing isn't as smart about floating point numbers. But past that, most operations actually have a third parameter, implicitly added when you use the binary operators - the rounding mode. The IEEE754 spec supports multiple rounding modes (round-to-nearest, round-to-zero, round-to-positive, etc), so z3 has to support them. If you want to specify the rounding mode for an operation, use the fp operation explicitly (`claripy.fpAdd` for example) with a rounding mode (one of `claripy.fp.RM_*`) as the first argument.

Constraints and solving work in the same way, but with `eval` returning a floating point number:

```
>>> state.solver.add(b + 2 < 0)
>>> state.solver.add(b + 2 > -1)
>>> state.solver.eval(b)
-2.4999999999999996
```

This is nice, but sometimes we need to be able to work directly with the representation of the float as a bitvector. You can interpret bitvectors as floats and vice versa, with the methods `raw_to_bv` and `raw_to_fp`:

```
>>> a.raw_to_bv()
<BV64 0x400999999999999a>
>>> b.raw_to_bv()
<BV64 fpToIEEEBV(FPS('FP_b_0_64', DOUBLE))>

>>> claripy.BVV(0, 64).raw_to_fp()
<FP64 FPV(0.0, DOUBLE)>
>>> claripy.BVS('x', 64).raw_to_fp()
<FP64 fpToFP(x_1_64, DOUBLE)>
```

These conversions preserve the bit-pattern, as if you casted a float pointer to an int pointer or vice versa. However, if you want to preserve the value as closely as possible, as if you casted a float to an int (or vice versa), you can use a different set of methods, `val_to_fp` and `val_to_bv`. These methods must take the size or sort of the target value as a parameter, due to the floating-point nature of floats.

```
>>> a
<FP64 FPV(3.2, DOUBLE)>
>>> a.val_to_bv(12)
<BV12 0x3>
>>> a.val_to_bv(12).val_to_fp(claripy.fp.FSORT_FLOAT)
<FP32 FPV(3.0, FLOAT)>
```

These methods can also take a `signed` parameter, designating the signedness of the source or target bitvector.

### 3.3.5 More Solving Methods

`eval` will give you one possible solution to an expression, but what if you want several? What if you want to ensure that the solution is unique? The solver provides you with several methods for common solving patterns:

- `solver.eval(expression)` will give you one possible solution to the given expression.
- `solver.eval_one(expression)` will give you the solution to the given expression, or throw an error if more than one solution is possible.
- `solver.eval_upto(expression, n)` will give you up to n solutions to the given expression, returning fewer than n if fewer than n are possible.

- `solver.eval_atleast(expression, n)` will give you n solutions to the given expression, throwing an error if fewer than n are possible.
- `solver.eval_exact(expression, n)` will give you n solutions to the given expression, throwing an error if fewer or more than are possible.
- `solver.min(expression)` will give you the minimum possible solution to the given expression.
- `solver.max(expression)` will give you the maximum possible solution to the given expression.

Additionally, all of these methods can take the following keyword arguments:

- `extra_constraints` can be passed as a tuple of constraints. These constraints will be taken into account for this evaluation, but will not be added to the state.
- `cast_to` can be passed a data type to cast the result to. Currently, this can only be `int` and `bytes`, which will cause the method to return the corresponding representation of the underlying data. For example, `state.solver.eval(claripy.BVV(0x41424344, 32), cast_to=bytes)` will return `b'ABCD'`.

### 3.3.6 Summary

That was a lot!! After reading this, you should be able to create and manipulate bitvectors, booleans, and floating point values to form trees of operations, and then query the constraint solver attached to a state for possible solutions under a set of constraints. Hopefully by this point you understand the power of using ASTs to represent computations, and the power of a constraint solver.

In the appendix, you can find a reference for all the additional operations you can apply to ASTs, in case you ever need a quick table to look at.

## 3.4 Machine State - memory, registers, and so on

So far, we've only used angr's simulated program states (`SimState` objects) in the barest possible way in order to demonstrate basic concepts about angr's operation. Here, you'll learn about the structure of a state object and how to interact with it in a variety of useful ways.

### 3.4.1 Review: Reading and writing memory and registers

If you've been reading this book in order (and you should be, at least for this first section), you already saw the basics of how to access memory and registers. `state.regs` provides read and write access to the registers through attributes with the names of each register, and `state.mem` provides typed read and write access to memory with index-access notation to specify the address followed by an attribute access to specify the type you would like to interpret the memory as.

Additionally, you should now know how to work with ASTs, so you can now understand that any bitvector-typed AST can be stored in registers or memory.

Here are some quick examples for copying and performing operations on data from the state:

```
>>> import angr
>>> proj = angr.Project('/bin/true')
>>> state = proj.factory.entry_state()

# copy rsp to rbp
>>> state.regs.rbp = state.regs.rsp

# store rdx to memory at 0x1000
>>> state.mem[0x1000].uint64_t = state.regs.rdx
```

(continues on next page)

(continued from previous page)

```
# dereference rbp
>>> state.regs.rbp = state.mem[state.regs.rbp].uint64_t.resolved

# add rax, qword ptr [rsp + 8]
>>> state.regs.rax += state.mem[state.regs.rsp + 8].uint64_t.resolved
```

### 3.4.2 Basic Execution

Earlier, we showed how to use a Simulation Manager to do some basic execution. We'll show off the full capabilities of the simulation manager in the next chapter, but for now we can use a much simpler interface to demonstrate how symbolic execution works: `state.step()`. This method will perform one step of symbolic execution and return an object called *angr.engines.successors.SimSuccessors*. Unlike normal emulation, symbolic execution can produce several successor states that can be classified in a number of ways. For now, what we care about is the `.successors` property of this object, which is a list containing all the "normal" successors of a given step.

Why a list, instead of just a single successor state? Well, angr's process of symbolic execution is just the taking the operations of the individual instructions compiled into the program and performing them to mutate a SimState. When a line of code like `if (x > 4)` is reached, what happens if x is a symbolic bitvector? Somewhere in the depths of angr, the comparison `x > 4` is going to get performed, and the result is going to be `<Bool x_32_1 > 4>`.

That's fine, but the next question is, do we take the "true" branch or the "false" one? The answer is, we take both! We generate two entirely separate successor states - one simulating the case where the condition was true and simulating the case where the condition was false. In the first state, we add `x > 4` as a constraint, and in the second state, we add `!(x > 4)` as a constraint. That way, whenever we perform a constraint solve using either of these successor states, *the conditions on the state ensure that any solutions we get are valid inputs that will cause execution to follow the same path that the given state has followed.*

To demonstrate this, let's use a *fake firmware image* <*../examples/fauxware/fauxware*> as an example. If you look at the *source code* <*../examples/fauxware/fauxware.c*> for this binary, you'll see that the authentication mechanism for the firmware is backdoored; any username can be authenticated as an administrator with the password "SOSNEAKY". Furthermore, the first comparison against user input that happens is the comparison against the backdoor, so if we step until we get more than one successor state, one of those states will contain conditions constraining the user input to be the backdoor password. The following snippet implements this:

```
>>> proj = angr.Project('examples/fauxware/fauxware')
>>> state = proj.factory.entry_state(stdin=angr.SimFile)  # ignore that argument for now
↪- we're disabling a more complicated default setup for the sake of education
>>> while True:
...     succ = state.step()
...     if len(succ.successors) == 2:
...         break
...     state = succ.successors[0]

>>> state1, state2 = succ.successors
>>> state1
<SimState @ 0x400629>
>>> state2
<SimState @ 0x400699
```

Don't look at the constraints on these states directly - the branch we just went through involves the result of `strcmp`, which is a tricky function to emulate symbolically, and the resulting constraints are *very* complicated.

The program we emulated took data from standard input, which angr treats as an infinite stream of symbolic data by default. To perform a constraint solve and get a possible value that input could have taken in order to satisfy the

constraints, we'll need to get a reference to the actual contents of stdin. We'll go over how our file and input subsystems work later on this very page, but for now, just use `state.posix.stdin.load(0, state.posix.stdin.size)` to retrieve a bitvector representing all the content read from stdin so far.

```
>>> input_data = state1.posix.stdin.load(0, state1.posix.stdin.size)

>>> state1.solver.eval(input_data, cast_to=bytes)
b'\x00\x00\x00\x00\x00\x00\x00\x00\x00SOSNEAKY\x00\x00\x00'

>>> state2.solver.eval(input_data, cast_to=bytes)
b'\x00\x00\x00\x00\x00\x00\x00\x00\x00S\x00\x80N\x00\x00 \x00\x00\x00\x00'
```

As you can see, in order to go down the `state1` path, you must have given as a password the backdoor string "SOSNEAKY". In order to go down the `state2` path, you must have given something *besides* "SOSNEAKY". z3 has helpfully provided one of the billions of strings fitting this criteria.

Fauxware was the first program angr's symbolic execution ever successfully worked on, back in 2013. By finding its backdoor using angr you are participating in a grand tradition of having a bare-bones understanding of how to use symbolic execution to extract meaning from binaries!

### 3.4.3 State Presets

So far, whenever we've been working with a state, we've created it with `project.factory.entry_state()`. This is just one of several *state constructors* available on the project factory:

- `.blank_state()` constructs a "blank slate" blank state, with most of its data left uninitialized. When accessing uninitialized data, an unconstrained symbolic value will be returned.
- `.entry_state()` constructs a state ready to execute at the main binary's entry point.
- `.full_init_state()` constructs a state that is ready to execute through any initializers that need to be run before the main binary's entry point, for example, shared library constructors or preinitializers. When it is finished with these it will jump to the entry point.
- `.call_state()` constructs a state ready to execute a given function.

You can customize the state through several arguments to these constructors:

- All of these constructors can take an `addr` argument to specify the exact address to start.
- If you're executing in an environment that can take command line arguments or an environment, you can pass a list of arguments through `args` and a dictionary of environment variables through `env` into `entry_state` and `full_init_state`. The values in these structures can be strings or bitvectors, and will be serialized into the state as the arguments and environment to the simulated execution. The default `args` is an empty list, so if the program you're analyzing expects to find at least an `argv[0]`, you should always provide that!
- If you'd like to have `argc` be symbolic, you can pass a symbolic bitvector as `argc` to the `entry_state` and `full_init_state` constructors. Be careful, though: if you do this, you should also add a constraint to the resulting state that your value for argc cannot be larger than the number of args you passed into `args`.
- To use the call state, you should call it with `.call_state(addr, arg1, arg2, ...)`, where `addr` is the address of the function you want to call and `argN` is the Nth argument to that function, either as a Python integer, string, or array, or a bitvector. If you want to have memory allocated and actually pass in a pointer to an object, you should wrap it in an PointerWrapper, i.e. `angr.PointerWrapper("point to me!")`. The results of this API can be a little unpredictable, but we're working on it.
- To specify the calling convention used for a function with `call_state`, you can pass a *SimCC* instance as the `cc` argument. We try to pick a sane default, but for special cases you will need to help angr out.

There are several more options that can be used in any of these constructors! See the docs on the `project.factory` object (an *angr.factory.AngrObjectFactory*) for more details.

### 3.4.4 Low level interface for memory

The `state.mem` interface is convenient for loading typed data from memory, but when you want to do raw loads and stores to and from ranges of memory, it's very cumbersome. It turns out that `state.mem` is actually just a bunch of logic to correctly access the underlying memory storage, which is just a flat address space filled with bitvector data: `state.memory`. You can use `state.memory` directly with the `.load(addr, size)` and `.store(addr, val)` methods:

```
>>> s = proj.factory.blank_state()
>>> s.memory.store(0x4000, angr.claripy.BVV(0x0123456789abcdef0123456789abcdef, 128))
>>> s.memory.load(0x4004, 6) # load-size is in bytes
<BV48 0x89abcdef0123>
```

As you can see, the data is loaded and stored in a "big-endian" fashion, since the primary purpose of `state.memory` is to load an store swaths of data with no attached semantics. However, if you want to perform a byteswap on the loaded or stored data, you can pass a keyword argument `endness` - if you specify little-endian, byteswap will happen. The endness should be one of the members of the `Endness` enum in the `archinfo` package used to hold declarative data about CPU architectures for angr. Additionally, the endness of the program being analyzed can be found as `arch.memory_endness` - for instance `state.arch.memory_endness`.

```
>>> import archinfo
>>> s.memory.load(0x4000, 4, endness=archinfo.Endness.LE)
<BV32 0x67452301>
```

There is also a low-level interface for register access, `state.registers`, that uses the exact same API as `state.memory`, but explaining its behavior involves a *dive* into the abstractions that angr uses to seamlessly work with multiple architectures. The short version is that it is simply a register file, with the mapping between registers and offsets defined in archinfo.

### 3.4.5 State Options

There are a lot of little tweaks that can be made to the internals of angr that will optimize behavior in some situations and be a detriment in others. These tweaks are controlled through state options.

On each SimState object, there is a set (`state.options`) of all its enabled options. Each option (really just a string) controls the behavior of angr's execution engine in some minute way. A listing of the full domain of options, along with the defaults for different state types, can be found in *the appendix*. You can access an individual option for adding to a state through `angr.options`. The individual options are named with CAPITAL_LETTERS, but there are also common groupings of objects that you might want to use bundled together, named with lowercase_letters.

When creating a SimState through any constructor, you may pass the keyword arguments `add_options` and `remove_options`, which should be sets of options that modify the initial options set from the default.

```
# Example: enable lazy solves, an option that causes state satisfiability to be checked␣
↪as infrequently as possible.
# This change to the settings will be propagated to all successor states created from␣
↪this state after this line.
>>> s.options.add(angr.options.LAZY_SOLVES)

# Create a new state with lazy solves enabled
>>> s = proj.factory.entry_state(add_options={angr.options.LAZY_SOLVES})
```

(continues on next page)

(continued from previous page)

```
# Create a new state without simplification options enabled
>>> s = proj.factory.entry_state(remove_options=angr.options.simplification)
```

### 3.4.6 State Plugins

With the exception of the set of options just discussed, everything stored in a SimState is actually stored in a *plugin* attached to the state. Almost every property on the state we've discussed so far is a plugin - `memory`, `registers`, `mem`, `regs`, `solver`, etc. This design allows for code modularity as well as the ability to easily *implement new kinds of data storage* for other aspects of an emulated state, or the ability to provide alternate implementations of plugins.

For example, the normal `memory` plugin simulates a flat memory space, but analyses can choose to enable the "abstract memory" plugin, which uses alternate data types for addresses to simulate free-floating memory mappings independent of address, to provide `state.memory`. Conversely, plugins can reduce code complexity: `state.memory` and `state.registers` are actually two different instances of the same plugin, since the registers are emulated with an address space as well.

#### The globals plugin

`state.globals` is an extremely simple plugin: it implements the interface of a standard Python dict, allowing you to store arbitrary data on a state.

#### The history plugin

`state.history` is a very important plugin storing historical data about the path a state has taken during execution. It is actually a linked list of several history nodes, each one representing a single round of execution—you can traverse this list with `state.history.parent.parent` etc.

To make it more convenient to work with this structure, the history also provides several efficient iterators over the history of certain values. In general, these values are stored as `history.recent_NAME` and the iterator over them is just `history.NAME`. For example, `for addr in state.history.bbl_addrs: print hex(addr)` will print out a basic block address trace for the binary, while `state.history.recent_bbl_addrs` is the list of basic blocks executed in the most recent step, `state.history.parent.recent_bbl_addrs` is the list of basic blocks executed in the previous step, etc. If you ever need to quickly obtain a flat list of these values, you can access `.hardcopy`, e.g. `state.history.bbl_addrs.hardcopy`. Keep in mind though, index-based accessing is implemented on the iterators.

Here is a brief listing of some of the values stored in the history:

- `history.descriptions` is a listing of string descriptions of each of the rounds of execution performed on the state.
- `history.bbl_addrs` is a listing of the basic block addresses executed by the state. There may be more than one per round of execution, and not all addresses may correspond to binary code - some may be addresses at which SimProcedures are hooked.
- `history.jumpkinds` is a listing of the disposition of each of the control flow transitions in the state's history, as VEX enum strings.
- `history.jump_guards` is a listing of the conditions guarding each of the branches that the state has encountered.
- `history.events` is a semantic listing of "interesting events" which happened during execution, such as the presence of a symbolic jump condition, the program popping up a message box, or execution terminating with an exit code.
- `history.actions` is usually empty, but if you add the `angr.options.refs` options to the state, it will be populated with a log of all the memory, register, and temporary value accesses performed by the program.

#### The callstack plugin

angr will track the call stack for the emulated program. On every call instruction, a frame will be added to the top of the tracked callstack, and whenever the stack pointer drops below the point where the topmost frame was called, a frame is popped. This allows angr to robustly store data local to the current emulated function.

Similar to the history, the callstack is also a linked list of nodes, but there are no provided iterators over the contents of the nodes - instead you can directly iterate over `state.callstack` to get the callstack frames for each of the active frames, in order from most recent to oldest. If you just want the topmost frame, this is `state.callstack`.

- `callstack.func_addr` is the address of the function currently being executed
- `callstack.call_site_addr` is the address of the basic block which called the current function
- `callstack.stack_ptr` is the value of the stack pointer from the beginning of the current function
- `callstack.ret_addr` is the location that the current function will return to if it returns

### 3.4.7 More about I/O: Files, file systems, and network sockets

Please refer to *Working with File System, Sockets, and Pipes* for a more complete and detailed documentation of how I/O is modeled in angr.

### 3.4.8 Copying and Merging

A state supports very fast copies, so that you can explore different possibilities:

```
>>> proj = angr.Project('/bin/true')
>>> s = proj.factory.blank_state()
>>> s1 = s.copy()
>>> s2 = s.copy()

>>> s1.mem[0x1000].uint32_t = 0x41414141
>>> s2.mem[0x1000].uint32_t = 0x42424242
```

States can also be merged together.

```
# merge will return a tuple. the first element is the merged state
# the second element is a symbolic variable describing a state flag
# the third element is a boolean describing whether any merging was done
>>> (s_merged, m, anything_merged) = s1.merge(s2)

# this is now an expression that can resolve to "AAAA" *or* "BBBB"
>>> aaaa_or_bbbb = s_merged.mem[0x1000].uint32_t
```

**Todo**

describe limitations of merging

## 3.5 Simulation Managers

The most important control interface in angr is the SimulationManager, which allows you to control symbolic execution over groups of states simultaneously, applying search strategies to explore a program's state space. Here, you'll learn how to use it.

Simulation managers let you wrangle multiple states in a slick way. States are organized into "stashes", which you can step forward, filter, merge, and move around as you wish. This allows you to, for example, step two different stashes of states at different rates, then merge them together. The default stash for most operations is the `active` stash, which is where your states get put when you initialize a new simulation manager.

### 3.5.1 Stepping

The most basic capability of a simulation manager is to step forward all states in a given stash by one basic block. You do this with `.step()`.

```
>>> import angr
>>> proj = angr.Project('examples/fauxware/fauxware', auto_load_libs=False)
>>> state = proj.factory.entry_state()
>>> simgr = proj.factory.simgr(state)
>>> simgr.active
[<SimState @ 0x400580>]

>>> simgr.step()
>>> simgr.active
[<SimState @ 0x400540>]
```

Of course, the real power of the stash model is that when a state encounters a symbolic branch condition, both of the successor states appear in the stash, and you can step both of them in sync. When you don't really care about controlling analysis very carefully and you just want to step until there's nothing left to step, you can just use the `.run()` method.

```
# Step until the first symbolic branch
>>> while len(simgr.active) == 1:
...     simgr.step()

>>> simgr
<SimulationManager with 2 active>
>>> simgr.active
[<SimState @ 0x400692>, <SimState @ 0x400699>]

# Step until everything terminates
>>> simgr.run()
>>> simgr
<SimulationManager with 3 deadended>
```

We now have 3 deadended states! When a state fails to produce any successors during execution, for example, because it reached an `exit` syscall, it is removed from the active stash and placed in the `deadended` stash.

### 3.5.2 Stash Management

Let's see how to work with other stashes.

To move states between stashes, use `.move()`, which takes `from_stash`, `to_stash`, and `filter_func` (optional, default is to move everything). For example, let's move everything that has a certain string in its output:

```
>>> simgr.move(from_stash='deadended', to_stash='authenticated', filter_func=lambda s: b
↪'Welcome' in s.posix.dumps(1))
>>> simgr
<SimulationManager with 2 authenticated, 1 deadended>
```

We were able to just create a new stash named "authenticated" just by asking for states to be moved to it. All the states in this stash have "Welcome" in their stdout, which is a fine metric for now.

Each stash is just a list, and you can index into or iterate over the list to access each of the individual states, but there are some alternate methods to access the states too. If you prepend the name of a stash with `one_`, you will be given the first state in the stash. If you prepend the name of a stash with `mp_`, you will be given a mulpyplexed version of the stash.

```
>>> for s in simgr.deadended + simgr.authenticated:
...     print(hex(s.addr))
0x1000030
0x1000078
0x1000078

>>> simgr.one_deadended
<SimState @ 0x1000030>
>>> simgr.mp_authenticated
MP([<SimState @ 0x1000078>, <SimState @ 0x1000078>])
>>> simgr.mp_authenticated.posix.dumps(0)
MP(['\x00\x00\x00\x00\x00\x00\x00\x00\x00SOSNEAKY\x00',
    '\x00\x00\x00\x00\x00\x00\x00\x00\x00S\x80\x80\x80\x80@\x80@\x00'])
```

Of course, `step`, `run`, and any other method that operates on a single stash of paths can take a `stash` argument, specifying which stash to operate on.

There are lots of fun tools that the simulation manager provides you for managing your stashes. We won't go into the rest of them for now, but you should check out the API documentation.

### Stash types

You can use stashes for whatever you like, but there are a few stashes that will be used to categorize some special kinds of states. These are:

| Stash | Description |
|---|---|
| active | This stash contains the states that will be stepped by default, unless an alternate stash is specified. |
| deadended | A state goes to the deadended stash when it cannot continue the execution for some reason, including no more valid instructions, unsat state of all of its successors, or an invalid instruction pointer. |
| pruned | When using `LAZY_SOLVES`, states are not checked for satisfiability unless absolutely necessary. When a state is found to be unsat in the presence of `LAZY_SOLVES`, the state hierarchy is traversed to identify when, in its history, it initially became unsat. All states that are descendants of that point (which will also be unsat, since a state cannot become un-unsat) are pruned and put in this stash. |
| unconstrained | If the `save_unconstrained` option is provided to the SimulationManager constructor, states that are determined to be unconstrained (i.e., with the instruction pointer controlled by user data or some other source of symbolic data) are placed here. |
| unsat | If the `save_unsat` option is provided to the SimulationManager constructor, states that are determined to be unsatisfiable (i.e., they have constraints that are contradictory, like the input having to be both "AAAA" and "BBBB" at the same time) are placed here. |

There is another list of states that is not a stash: `errored`. If, during execution, an error is raised, then the state will be wrapped in an `ErrorRecord` object, which contains the state and the error it raised, and then the record will be inserted into `errored`. You can get at the state as it was at the beginning of the execution tick that caused the error with `record.state`, you can see the error that was raised with `record.error`, and you can launch a debug shell at the site of the error with `record.debug()`. This is an invaluable debugging tool!

### 3.5.3 Simple Exploration

An extremely common operation in symbolic execution is to find a state that reaches a certain address, while discarding all states that go through another address. Simulation manager has a shortcut for this pattern, the `.explore()` method.

When launching `.explore()` with a `find` argument, execution will run until a state is found that matches the find condition, which can be the address of an instruction to stop at, a list of addresses to stop at, or a function which takes a state and returns whether it meets some criteria. When any of the states in the active stash match the `find` condition, they are placed in the `found` stash, and execution terminates. You can then explore the found state, or decide to discard it and continue with the other ones. You can also specify an `avoid` condition in the same format as `find`. When a state matches the avoid condition, it is put in the `avoided` stash, and execution continues. Finally, the `num_find` argument controls the number of states that should be found before returning, with a default of 1. Of course, if you run out of states in the active stash before finding this many solutions, execution will stop anyway.

Let's look at a simple crackme example:

First, we load the binary.

```
>>> proj = angr.Project('examples/CSCI-4968-MBE/challenges/crackme0x00a/crackme0x00a')
```

Next, we create a SimulationManager.

```
>>> simgr = proj.factory.simgr()
```

Now, we symbolically execute until we find a state that matches our condition (i.e., the "win" condition).

```
>>> simgr.explore(find=lambda s: b"Congrats" in s.posix.dumps(1))
<SimulationManager with 1 active, 1 found>
```

Now, we can get the flag out of that state!

```
>>> s = simgr.found[0]
>>> print(s.posix.dumps(1))
Enter password: Congrats!

>>> flag = s.posix.dumps(0)
>>> print(flag)
g00dJ0B!
```

Pretty simple, isn't it?

Other examples can be found by browsing the *examples*.

#### Exploration Techniques

angr ships with several pieces of canned functionality that let you customize the behavior of a simulation manager, called *exploration techniques*. The archetypical example of why you would want an exploration technique is to modify the pattern in which the state space of the program is explored - the default "step everything at once" strategy is effectively breadth-first search, but with an exploration technique you could implement, for example, depth-first search. However, the instrumentation power of these techniques is much more flexible than that - you can totally alter the behavior of angr's stepping process. Writing your own exploration techniques will be covered in a later chapter.

To use an exploration technique, call `simgr.use_technique(tech)`, where tech is an instance of an ExplorationTechnique subclass. angr's built-in exploration techniques can be found under `angr.exploration_techniques`.

Here's a quick overview of some of the built-in ones:

- *DFS*: Depth first search, as mentioned earlier. Keeps only one state active at once, putting the rest in the `deferred` stash until it deadends or errors.

- *Explorer*: This technique implements the `.explore()` functionality, allowing you to search for and avoid addresses.
- *LengthLimiter*: Puts a cap on the maximum length of the path a state goes through.
- *LoopSeer*: Uses a reasonable approximation of loop counting to discard states that appear to be going through a loop too many times, putting them in a `spinning` stash and pulling them out again if we run out of otherwise viable states.
- *ManualMergepoint*: Marks an address in the program as a merge point, so states that reach that address will be briefly held, and any other states that reach that same point within a timeout will be merged together.
- *MemoryWatcher*: Monitors how much memory is free/available on the system between simgr steps and stops exploration if it gets too low.
- *Oppologist*: The "operation apologist" is an especially fun gadget - if this technique is enabled and angr encounters an unsupported instruction, for example a bizarre and foreign floating point SIMD op, it will concretize all the inputs to that instruction and emulate the single instruction using the unicorn engine, allowing execution to continue.
- *Spiller*: When there are too many states active, this technique can dump some of them to disk in order to keep memory consumption low.
- *Threading*: Adds thread-level parallelism to the stepping process. This doesn't help much because of Python's global interpreter locks, but if you have a program whose analysis spends a lot of time in angr's native-code dependencies (unicorn, z3, libvex) you can seem some gains.
- *Tracer*: An exploration technique that causes execution to follow a dynamic trace recorded from some other source. The dynamic tracer repository has some tools to generate those traces.
- *Veritesting*: An implementation of a CMU paper on automatically identifying useful merge points. This is so useful, you can enable it automatically with `veritesting=True` in the SimulationManager constructor! Note that it frequenly doesn't play nice with other techniques due to the invasive way it implements static symbolic execution.

Look at the API documentation for the *SimulationManager* and `ExplorationTechnique` classes for more information.

## 3.6 Simulation and Instrumentation

When you ask for a step of execution to happen in angr, something has to actually perform the step. angr uses a series of engines (subclasses of the `SimEngine` class) to emulate the effects that of a given section of code has on an input state. The execution core of angr simply tries all the available engines in sequence, taking the first one that is able to handle the step. The following is the default list of engines, in order:

- The failure engine kicks in when the previous step took us to some uncontinuable state
- The syscall engine kicks in when the previous step ended in a syscall
- The hook engine kicks in when the current address is hooked
- The unicorn engine kicks in when the `UNICORN` state option is enabled and there is no symbolic data in the state
- The VEX engine kicks in as the final fallback.

### 3.6.1 SimSuccessors

The code that actually tries all the engines in turn is `project.factory.successors(state, **kwargs)`, which passes its arguments onto each of the engines. This function is at the heart of `state.step()` and `simulation_manager.step()`. It returns a SimSuccessors object, which we discussed briefly before. The purpose

of SimSuccessors is to perform a simple categorization of the successor states, stored in various list attributes. They are:

| Attribut | Guard Condition | Instruction Pointer | Description |
|---|---|---|---|
| succ | True (can be symbolic, but constrained to True) | Can be symbolic (but 256 solutions or less; see unconstr | A normal, satisfiable successor state to the state processed by the engine. The instruction pointer of this state may be symbolic (i.e., a computed jump based on user input), so the state might actually represent *several* potential continuations of execution going forward. |
| unsa | False (can be symbolic, but constrained to False). | Can be symbolic. | Unsatisfiable successors. These are successors whose guard conditions can only be false (i.e., jumps that cannot be taken, or the default branch of jumps that *must* be taken). |
| flat | True (can be symbolic, but constrained to True). | Concrete value. | As noted above, states in the `successors` list can have symbolic instruction pointers. This is rather confusing, as elsewhere in the code (i.e., in `SimEngineVEX.process`, when it's time to step that state forward), we make assumptions that a single program state only represents the execution of a single spot in the code. To alleviate this, when we encounter states in `successors` with symbolic instruction pointers, we compute all possible concrete solutions (up to an arbitrary threshold of 256) for them, and make a copy of the state for each such solution. We call this process "flattening". These `flat_successors` are states, each of which has a different, concrete instruction pointer. For example, if the instruction pointer of a state in `successors` was `X+5`, where `X` had constraints of `X > 0x800000` and `X <= 0x800010`, we would flatten it into 16 different `flat_successors` states, one with an instruction pointer of `0x800006`, one with `0x800007`, and so on until `0x800015`. |
| unco | True (can be symbolic, but constrained to True). | Symbolic (with more than 256 solutions). | During the flattening procedure described above, if it turns out that there are more than 256 possible solutions for the instruction pointer, we assume that the instruction pointer has been overwritten with unconstrained data (i.e., a stack overflow with user data). *This assumption is not sound in general*. Such states are placed in `unconstrained_successors` and not in `successors`. |
| all_ | Anything | Can be symbolic. | This is `successors + unsat_successors + unconstrained_successors`. |

### 3.6.2 Breakpoints

**Todo**

rewrite this to fix the narrative

Like any decent execution engine, angr supports breakpoints. This is pretty cool! A point is set as follows:

```
>>> import angr
>>> b = angr.Project('examples/fauxware/fauxware')

# get our state
>>> s = b.factory.entry_state()

# add a breakpoint. This breakpoint will drop into ipdb right before a memory write␣
↪happens.
>>> s.inspect.b('mem_write')

# on the other hand, we can have a breakpoint trigger right *after* a memory write␣
↪happens.
# we can also have a callback function run instead of opening ipdb.
>>> def debug_func(state):
...     print(f"State {state} is about to do a memory write!")

>>> s.inspect.b('mem_write', when=angr.BP_AFTER, action=debug_func)

# or, you can have it drop you in an embedded IPython!
>>> s.inspect.b('mem_write', when=angr.BP_AFTER, action=angr.BP_IPYTHON)
```

There are many other places to break than a memory write. Here is the list. You can break at BP_BEFORE or BP_AFTER for each of these events.

| Event type | Event meaning |
|---|---|
| mem_read | Memory is being read. |
| mem_write | Memory is being written. |
| address_concretization | A symbolic memory access is being resolved. |
| reg_read | A register is being read. |
| reg_write | A register is being written. |
| tmp_read | A temp is being read. |
| tmp_write | A temp is being written. |
| expr | An expression is being created (i.e., a result of an arithmetic operation or a constant in the IR). |
| statement | An IR statement is being translated. |
| instruction | A new (native) instruction is being translated. |
| irsb | A new basic block is being translated. |
| constraints | New constraints are being added to the state. |
| exit | A successor is being generated from execution. |
| fork | A symbolic execution state has forked into multiple states. |
| symbolic_variable | A new symbolic variable is being created. |
| call | A call instruction is hit. |
| return | A ret instruction is hit. |
| simprocedure | A simprocedure (or syscall) is executed. |
| dirty | A dirty IR callback is executed. |
| syscall | A syscall is executed (called in addition to the simprocedure event). |
| engine_process | A SimEngine is about to process some code. |

These events expose different attributes:

| Event type | Attribute name | Attribute availability | Attribute meaning |
|---|---|---|---|
| mem_read | mem_read_address | BP_BEFORE or BP_AFTER | The address at which memory is being read. |
| mem_read | mem_read_expr | BP_AFTER | The expression at that address. |
| mem_read | mem_read_length | BP_BEFORE or BP_AFTER | The length of the memory read. |
| mem_read | mem_read_condition | BP_BEFORE or BP_AFTER | The condition of the memory read. |
| mem_write | mem_write_address | BP_BEFORE or BP_AFTER | The address at which memory is being written. |
| mem_write | mem_write_length | BP_BEFORE or BP_AFTER | The length of the memory write. |
| mem_write | mem_write_expr | BP_BEFORE or BP_AFTER | The expression that is being written. |
| mem_write | mem_write_condition | BP_BEFORE or BP_AFTER | The condition of the memory write. |
| reg_read | reg_read_offset | BP_BEFORE or BP_AFTER | The offset of the register being read. |
| reg_read | reg_read_length | BP_BEFORE or BP_AFTER | The length of the register read. |
| reg_read | reg_read_expr | BP_AFTER | The expression in the register. |

continues on next page

Table 1 – continued from previous page

| Event type | Attribute name | Attribute availability | Attribute meaning |
|---|---|---|---|
| reg_read | reg_read_condition | BP_BEFORE or BP_AFTER | The condition of the register read. |
| reg_write | reg_write_offset | BP_BEFORE or BP_AFTER | The offset of the register being written. |
| reg_write | reg_write_length | BP_BEFORE or BP_AFTER | The length of the register write. |
| reg_write | reg_write_expr | BP_BEFORE or BP_AFTER | The expression that is being written. |
| reg_write | reg_write_condition | BP_BEFORE or BP_AFTER | The condition of the register write. |
| tmp_read | tmp_read_num | BP_BEFORE or BP_AFTER | The number of the temp being read. |
| tmp_read | tmp_read_expr | BP_AFTER | The expression of the temp. |
| tmp_write | tmp_write_num | BP_BEFORE or BP_AFTER | The number of the temp written. |
| tmp_write | tmp_write_expr | BP_AFTER | The expression written to the temp. |
| expr | expr | BP_BEFORE or BP_AFTER | The IR expression. |
| expr | expr_result | BP_AFTER | The value (e.g. AST) which the expression was evaluated to. |
| statement | statement | BP_BEFORE or BP_AFTER | The index of the IR statement (in the IR basic block). |
| instruction | instruction | BP_BEFORE or BP_AFTER | The address of the native instruction. |
| irsb | address | BP_BEFORE or BP_AFTER | The address of the basic block. |
| constraints | added_constraints | BP_BEFORE or BP_AFTER | The list of constraint expressions being added. |
| call | function_address | BP_BEFORE or BP_AFTER | The name of the function being called. |
| exit | exit_target | BP_BEFORE or BP_AFTER | The expression representing the target of a SimExit. |
| exit | exit_guard | BP_BEFORE or BP_AFTER | The expression representing the guard of a SimExit. |
| exit | exit_jumpkind | BP_BEFORE or BP_AFTER | The expression representing the kind of SimExit. |
| symbolic_variable | symbolic_name | BP_AFTER | The name of the symbolic variable being created. The solver engine might modify this name (by appending a unique ID and length). Check the symbolic_expr for the final symbolic expression. |
| symbolic_variable | symbolic_size | BP_AFTER | The size of the symbolic variable being created. |

continues on next page

Table 1 – continued from previous page

| Event type | Attribute name | Attribute availability | Attribute meaning |
|---|---|---|---|
| symbolic_variable | symbolic_expr | BP_AFTER | The expression representing the new symbolic variable. |
| address_concretization | address_concretization_strateg | BP_BEFORE or BP_AFTER | The SimConcretizationStrategy being used to resolve the address. This can be modified by the breakpoint handler to change the strategy that will be applied. If your breakpoint handler sets this to None, this strategy will be skipped. |
| address_concretization | address_concretization_action | BP_BEFORE or BP_AFTER | The SimAction object being used to record the memory action. |
| address_concretization | address_concretization_memo | BP_BEFORE or BP_AFTER | The SimMemory object on which the action was taken. |
| address_concretization | address_concretization_expr | BP_BEFORE or BP_AFTER | The AST representing the memory index being resolved. The breakpoint handler can modify this to affect the address being resolved. |
| address_concretization | address_concretization_add_c | BP_BEFORE or BP_AFTER | Whether or not constraints should/will be added for this read. |
| address_concretization | address_concretization_result | BP_AFTER | The list of resolved memory addresses (integers). The breakpoint handler can overwrite these to effect a different resolution result. |
| syscall | syscall_name | BP_BEFORE or BP_AFTER | The name of the system call. |
| simprocedure | simprocedure_name | BP_BEFORE or BP_AFTER | The name of the simprocedure. |
| simprocedure | simprocedure_addr | BP_BEFORE or BP_AFTER | The address of the simprocedure. |
| simprocedure | simprocedure_result | BP_AFTER | The return value of the simprocedure. You can also *override* it in BP_BEFORE, which will cause the actual simprocedure to be skipped and for your return value to be used instead. |
| simprocedure | simprocedure | BP_BEFORE or BP_AFTER | The actual SimProcedure object. |

continues on next page

Table 1 – continued from previous page

| Event type | Attribute name | Attribute availability | Attribute meaning |
|---|---|---|---|
| dirty | dirty_name | BP_BEFORE or BP_AFTER | The name of the dirty call. |
| dirty | dirty_handler | BP_BEFORE | The function that will be run to handle the dirty call. You can override this. |
| dirty | dirty_args | BP_BEFORE or BP_AFTER | The address of the dirty. |
| dirty | dirty_result | BP_AFTER | The return value of the dirty call. You can also *override* it in BP_BEFORE, which will cause the actual dirty call to be skipped and for your return value to be used instead. |
| engine_process | sim_engine | BP_BEFORE or BP_AFTER | The SimEngine that is processing. |
| engine_process | successors | BP_BEFORE or BP_AFTER | The SimSuccessors object defining the result of the engine. |

These attributes can be accessed as members of `state.inspect.attrs` during the appropriate breakpoint callback to access the appropriate values. You can even modify these value to modify further uses of the values!

```
>>> def track_reads(state):
...     print('Read', state.inspect.attrs.mem_read_expr, 'from', state.inspect.attrs.mem_
↪read_address)
...
>>> s.inspect.b('mem_read', when=angr.BP_AFTER, action=track_reads)
```

Additionally, each of these properties can be used as a keyword argument to `inspect.b` to make the breakpoint conditional:

```
# This will break before a memory write if 0x1000 is a possible value of its target␣
↪expression
>>> s.inspect.b('mem_write', mem_write_address=0x1000)

# This will break before a memory write if 0x1000 is the *only* value of its target␣
↪expression
>>> s.inspect.b('mem_write', mem_write_address=0x1000, mem_write_address_unique=True)

# This will break after instruction 0x8000, but only 0x1000 is a possible value of the␣
↪last expression that was read from memory
>>> s.inspect.b('instruction', when=angr.BP_AFTER, instruction=0x8000, mem_read_
↪expr=0x1000)
```

Cool stuff! In fact, we can even specify a function as a condition:

```
# this is a complex condition that could do anything! In this case, it makes sure that␣
↪RAX is 0x41414141 and
# that the basic block starting at 0x8004 was executed sometime in this path's history
```

(continues on next page)

(continued from previous page)

```
>>> def cond(state):
...     return state.eval(state.regs.rax, cast_to=str) == 'AAAA' and 0x8004 in state.
↪inspect.attrs.backtrace

>>> s.inspect.b('mem_write', condition=cond)
```

That is some cool stuff!

#### Caution about `mem_read` breakpoint

The `mem_read` breakpoint gets triggered anytime there are memory reads by either the executing program or the binary analysis. If you are using breakpoint on `mem_read` and also using `state.mem` to load data from memory addresses, then know that the breakpoint will be fired as you are technically reading memory.

So if you want to load data from memory and not trigger any `mem_read` breakpoint you have had set up, then use `state.memory.load` with the keyword arguments `disable_actions=True` and `inspect=False`.

This is also true for `state.find` and you can use the same keyword arguments to prevent `mem_read` breakpoints from firing.

## 3.7 Analyses

angr's goal is to make it easy to carry out useful analyses on binary programs. To this end, angr allows you to package analysis code in a common format that can be easily applied to any project. We will cover writing your own analyses *Writing Analyses*, but the idea is that all the analyses appear under `project.analyses` (for example, `project.analyses.CFGFast()`) and can be called as functions, returning analysis result instances.

### 3.7.1 Built-in Analyses

| Name | Description |
|---|---|
| CFGFast | Constructs a fast *Control Flow Graph* of the program |
| CFGEmulated | Constructs an accurate *Control Flow Graph* of the program |
| VFG | Performs VSA on every function of the program, creating a *Value Flow Graph* and detecting stack variables |
| DDG | Calculates a *Data Dependency Graph*, allowing one to determine what statements a given value depends on |
| BackwardSlice | Computes a *Backward Slice* of a program with respect to a certain target |
| Identifier | Identifies common library functions in CGC binaries |
| More! | angr has quite a few analyses, most of which work! If you'd like to know how to use one, please submit an issue requesting documentation. |

### 3.7.2 Resilience

Analyses can be written to be resilient, and catch and log basically any error. These errors, depending on how they're caught, are logged to the `errors` or `named_errors` attribute of the analysis. However, you might want to run an analysis in "fail fast" mode, so that errors are not handled. To do this, the argument `fail_fast=True` can be passed into the analysis constructor.

## 3.8 Symbolic Execution

Symbolic execution is a program analysis technique used to explore multiple execution paths of a program simultaneously. Unlike normal execution, which runs the program with specific inputs, symbolic execution treats inputs as symbolic variables rather than concrete values. This means the execution can represent a wide range of inputs with symbolic expressions. Symbolic execution allows, at a time in emulation, to determine for a branch all conditions necessary to take a branch or not. Every variable is represented as a symbolic value, and each branch as a constraint. Thus, symbolic execution allows us to see which conditions allow the program to go from point A to point B by resolving these constraints. The execution paths are then analyzed by solving constraints generated by these symbolic expressions, allowing the discovery of bugs and vulnerabilities that might be missed in standard testing.

### 3.8.1 Example:

Consider the following simple program :

```
const char* check_value(int x) {
    if (x > 10) {
        return "Greater";
    } else {
        return "Lesser or Equal";
    }
}
```

In normal execution, if `x` is set to 5, the program will follow the path where `x <= 10` and return "Lesser or Equal". In symbolic execution, `x` is treated as a symbolic variable, `X`. The execution engine explores both paths:

- Path 1: `X > 10` leading to the result "Greater"
- Path 2: `X <= 10` leading to the result "Lesser or Equal"

Constraints for both paths are generated and solved to understand all possible behaviors of the program.

In software verification, it helps ensure that the code behaves as expected across all possible inputs and states. For security analysis, symbolic execution can uncover vulnerabilities such as input validation errors, which could be exploited by attackers. Additionally, in automated testing, it aids in generating comprehensive test cases that cover edge cases and rare execution paths, enhancing the robustness and security of software systems. Overall, symbolic execution provides a powerful means to rigorously analyze and improve software and firmware reliability.

### 3.8.2 Basic Execution

Now let's see an example use case of symbolic execution with angr. Consider the following example code,

```
void helloWorld() {
    printf("Hello, World!\n");
}

void firstCall(uint32_t num) {
    if (num > 50 && num <100)
        HelloWorld();
}
```

The `firstCall` function will accept a 32-bit number as an input and will call `helloWorld` function if the number is between 50 and 100.

You can perform a symbolic execution to find a correct and valid input to reach the final `helloWorld` function call with angr using the following sample code.

```
import angr
# Load the binary
project = angr.Project('./3func', auto_load_libs=False)

# Define the address of the firstCall function
firstCall_addr = project.loader.main_object.get_symbol("firstCall")

# Define the address of the helloWorld function
helloWorld_addr = project.loader.main_object.get_symbol("helloWorld")
# Create a symbolic variable for the firstCall arg
input_arg = angr.claripy.BVS('input_arg', 32)

# Create a blank state at the address of the firstCall function
init_state = project.factory.blank_state(addr=firstCall_addr.rebased_addr)

# Assuming the calling convention passes the argument in a register
# (e.g., x86 uses edi for the argument)
init_state.regs.edi = input_arg

# Create a simulation manager
simgr = project.factory.simulation_manager(init_state)

# Explore the binary, looking for the address of helloWorld
simgr.explore(find=helloWorld_addr.rebased_addr)

# Check if we found a state that reached the target
if simgr.found:
    input_value = simgr.found[0].solver.eval(input_arg)
    print(f"Value of input_arg that reaches HelloWorld: {input_value}")
    # Get the constraints for reaching the helloWorld function
    constraints = simgr.found[0].solver.constraints
    # Create a solver with the constraints
    solver = angr.claripy.Solver()
    solver.add(constraints)
    min_val = solver.min(input_arg)
    max_val = solver.max(input_arg)
    print(f"Function arg: min = {min_val}, max = {max_val}")
else:
    print("Did not find a state that reaches HelloWorld.")
```

It will produce the output like the below with a valid example function arg that can reach the function `helloWorld` that you can use as a test case.

```
Value of input_arg that reaches HelloWorld: 71
Function arg: min = 51, max = 99
```

## 3.9 A final word of advice

Congratulations! If you've read this far through the book (editor's note: this comment only really applies when we've actually finished writing all the TODOs so far) then you've been introduced to all the fundamental components of angr necessary to get started with binary analysis.

Ultimately, angr is just an emulator. It is a highly instrumentable and very unique emulator with lots of considerations

for environment, true, but at its core, the work you do with angr is about extracting knowledge about how a bunch of bytecode behaves on a CPU. In designing angr, we've tried to provide you with the tools and abstractions on top of this emulator to make certain common tasks more useful, but there's no problem you can't solve just by working with a SimState and observing the affects of `.step()`.

As you read further into this book, we'll describe more technical subjects and how to tune angr's behavior for complicated scenarios. This knowledge should inform your use of angr so you can take the quickest path to a solution to any given problem, but ultimately, you will want to solve problems by exercising creativity with the tools at your disposal. If you can take a problem and wrangle it into a form where it has defined and tractable inputs and outputs, you can absolutely use angr to achieve your goals, given that these goals involve analyzing binaries. None of the abstractions or instrumentations we provide are the end-all of how to use angr for a given task - angr is designed so it can be used in as integrated or as ad-hoc of a manner as you desire. If you see a path from problem to solution, take it.

Of course, it's very difficult to become well-acquainted with such a huge piece of technology as angr. To this end you can absolutely lean on the community (through the angr Discord server is the best option) to discuss angr and solving problems with it.

Good luck!

CHAPTER

FOUR

# BUILD-IN ANALYSES

## 4.1 Control-flow Graph Recovery (CFG)

angr includes analyses to recover the control-flow graph of a binary program. This also includes recovery of function boundaries, as well as reasoning about indirect jumps and other useful metadata.

### 4.1.1 General ideas

A basic analysis that one might carry out on a binary is a Control Flow Graph. A CFG is a graph with (conceptually) basic blocks as nodes and jumps/calls/rets/etc as edges.

In angr, there are two types of CFG that can be generated: a static CFG (CFGFast) and a dynamic CFG (CFGEmulated).

CFGFast uses static analysis to generate a CFG. It is significantly faster, but is theoretically bounded by the fact that some control-flow transitions can only be resolved at execution-time. This is the same sort of CFG analysis performed by other popular reverse-engineering tools, and its results are comparable with their output.

CFGEmulated uses symbolic execution to capture the CFG. While it is theoretically more accurate, it is dramatically slower. It is also typically less complete, due to issues with the accuracy of emulation (system calls, missing hardware features, and so on)

*If you are unsure which CFG to use, or are having problems with CFGEmulated, try CFGFast first.*

A CFG can be constructed by doing:

```
>>> import angr
# load your project
>>> p = angr.Project('/bin/true', load_options={'auto_load_libs': False})

# Generate a static CFG
>>> cfg = p.analyses.CFGFast()

# generate a dynamic CFG
>>> cfg = p.analyses.CFGEmulated(keep_state=True)
```

### 4.1.2 Using the CFG

The CFG, at its core, is a NetworkX di-graph. This means that all of the normal NetworkX APIs are available:

```
>>> print("This is the graph:", cfg.model.graph)
>>> print("It has %d nodes and %d edges" % (len(cfg.model.graph.nodes()), len(cfg.model.
↪graph.edges())))
```

The nodes of the CFG graph are instances of class `CFGNode`. Due to context sensitivity, a given basic block can have multiple nodes in the graph (for multiple contexts).

```
# this grabs *any* node at a given location:
>>> entry_node = cfg.model.get_any_node(p.entry)

# on the other hand, this grabs all of the nodes
>>> print("There were %d contexts for the entry block" % len(cfg.model.get_all_nodes(p.
↪entry)))

# we can also look up predecessors and successors
>>> print("Predecessors of the entry point:", entry_node.predecessors)
>>> print("Successors of the entry point:", entry_node.successors)
>>> print("Successors (and type of jump) of the entry point:", [ jumpkind + " to " +␣
↪str(node.addr) for node,jumpkind in cfg.model.get_successors_and_jumpkind(entry_node)␣
↪])
```

#### Viewing the CFG

Control-flow graph rendering is a hard problem. angr does not provide any built-in mechanism for rendering the output of a CFG analysis, and attempting to use a traditional graph rendering library, like matplotlib, will result in an unusable image.

One solution for viewing angr CFGs is found in axt's angr-utils repository.

### 4.1.3 Shared Libraries

The CFG analysis does not distinguish between code from different binary objects. This means that by default, it will try to analyze control flow through loaded shared libraries. This is almost never intended behavior, since this will extend the analysis time to several days, probably. To load a binary without shared libraries, add the following keyword argument to the `Project` constructor: `load_options={'auto_load_libs': False}`

### 4.1.4 Function Manager

The CFG result produces an object called the *Function Manager*, accessible through `cfg.kb.functions`. The most common use case for this object is to access it like a dictionary. It maps addresses to `Function` objects, which can tell you properties about a function.

```
>>> entry_func = cfg.kb.functions[p.entry]
```

Functions have several important properties!

- `entry_func.block_addrs` is a set of addresses at which basic blocks belonging to the function begin.
- `entry_func.blocks` is the set of basic blocks belonging to the function, that you can explore and disassemble using capstone.
- `entry_func.string_references()` returns a list of all the constant strings that were referred to at any point in the function. They are formatted as `(addr, string)` tuples, where addr is the address in the binary's data section the string lives, and string is a Python string that contains the value of the string.
- `entry_func.returning` is a boolean value signifying whether or not the function can return. `False` indicates that all paths do not return.
- `entry_func.callable` is an angr Callable object referring to this function. You can call it like a Python function with Python arguments and get back an actual result (may be symbolic) as if you ran the function with those arguments!

- `entry_func.transition_graph` is a NetworkX DiGraph describing control flow within the function itself. It resembles the control-flow graphs IDA displays on a per-function level.
- `entry_func.name` is the name of the function.
- `entry_func.has_unresolved_calls` and `entry.has_unresolved_jumps` have to do with detecting imprecision within the CFG. Sometimes, the analysis cannot detect what the possible target of an indirect call or jump could be. If this occurs within a function, that function will have the appropriate `has_unresolved_*` value set to `True`.
- `entry_func.get_call_sites()` returns a list of all the addresses of basic blocks which end in calls out to other functions.
- `entry_func.get_call_target(callsite_addr)` will, given `callsite_addr` from the list of call site addresses, return where that callsite will call out to.
- `entry_func.get_call_return(callsite_addr)` will, given `callsite_addr` from the list of call site addresses, return where that callsite should return to.

and many more !

### 4.1.5 CFGFast details

CFGFast performs a static control-flow and function recovery. Starting with the entry point (or any user-defined points) roughly the following procedure is performed:

1) The basic block is lifted to VEX IR, and all its exits (jumps, calls, returns, or continuation to the next block) are collected
2) For each exit, if this exit is a constant address, we add an edge to the CFG of the correct type, and add the destination block to the set of blocks to be analyzed.
3) In the event of a function call, the destination block is also considered the start of a new function. If the target function is known to return, the block after the call is also analyzed.
4) In the event of a return, the current function is marked as returning, and the appropriate edges in the callgraph and CFG are updated.
5) For all indirect jumps (block exits with a non-constant destination) Indirect Jump Resolution is performed.

#### Finding function starts

CFGFast supports multiple ways of deciding where a function starts and ends.

First the binary's main entry point will be analyzed. For binaries with symbols (e.g., non-stripped ELF and PE binaries) all function symbols will be used as possible starting points. For binaries without symbols, such as stripped binaries, or binaries loaded using the `blob` loader backend, CFG will scan the binary for a set of function prologues defined for the binary's architecture. Finally, by default, the binary's entire code section will be scanned for executable contents, regardless of prologues or symbols.

In addition to these, as with CFGEmulated, function starts will also be considered when they are the target of a "call" instruction on the given architecture.

All of these options can be disabled

#### FakeRets and function returns

When a function call is observed, we first assume that the callee function eventually returns, and treat the block after it as part of the caller function. This inferred control-flow edge is known as a "FakeRet". If, in analyzing the callee, we find this not to be true, we update the CFG, removing this "FakeRet", and updating the callgraph and function blocks accordingly. As such, the CFG is recovered *twice*. In doing this, the set of blocks in each function, and whether the function returns, can be recovered and propagated directly.

#### Indirect Jump Resolution

**Todo**

Document this.

#### CFGFast Options

These are the most useful options when working with CFGFast:

| Option | Description |
|---|---|
| force_complete_ | (Default: True) Treat the entire binary as code for the purposes of function detection. If you have a blob (e.g., mixed code and data) *you want to turn this off*. |
| function_starts | A list of addresses, to use as entry points into the analysis. |
| normalize | (Default: False) Normalize the resulting functions (e.g., each basic block belongs to at most one function, back-edges point to the start of basic blocks) |
| resolve_indirect_j | (Default: True) Perform additional analysis to attempt to find targets for every indirect jump found during CFG creation. |
| more! | Examine the docstring on p.analyses.CFGFast for more up-to-date options |

### 4.1.6 CFGEmulated details

#### CFGEmulated Options

The most common options for CFGEmulated include:

| Option | Description |
|---|---|
| context_sensitivity_level | This sets the context sensitivity level of the analysis. See the context sensitivity level section below for more information. This is 1 by default. |
| starts | A list of addresses, to use as entry points into the analysis. |
| avoid_runs | A list of addresses to ignore in the analysis. |
| call_depth | Limit the depth of the analysis to some number calls. This is useful for checking which functions a specific function can directly jump to (by setting `call_depth` to 1). |
| initial_state | An initial state can be provided to the CFG, which it will use throughout its analysis. |
| keep_state | To save memory, the state at each basic block is discarded by default. If `keep_state` is True, the state is saved in the CFGNode. |
| enable_symbolic_back_ | Whether to enable an intensive technique for resolving indirect jumps |
| enable_advanced_backv | Whether to enable another intensive technique for resolving direct jumps |
| more! | Examine the docstring on p.analyses.CFGEmulated for more up-to-date options |

#### Context Sensitivity Level

angr constructs a CFG by executing every basic block and seeing where it goes. This introduces some challenges: a basic block can act differently in different *contexts*. For example, if a block ends in a function return, the target of that return will be different, depending on different callers of the function containing that basic block.

The context sensitivity level is, conceptually, the number of such callers to keep on the callstack. To explain this concept, let's look at the following code:

```
void error(char *error)
{
    puts(error);
}

void alpha()
{
    puts("alpha");
    error("alpha!");
}

void beta()
{
    puts("beta");
    error("beta!");
}

void main()
{
    alpha();
    beta();
}
```

The above sample has four call chains: `main>alpha>puts`, `main>alpha>error>puts` and `main>beta>puts`, and `main>beta>error>puts`. While, in this case, angr can probably execute both call chains, this becomes unfeasible for larger binaries. Thus, angr executes the blocks with states limited by the context sensitivity level. That is, each function is re-analyzed for each unique context that it is called in.

For example, the `puts()` function above will be analyzed with the following contexts, given different context sensitivity levels:

| Level | Meaning | Contexts |
|---|---|---|
| 0 | Callee-only | `puts` |
| 1 | One caller, plus callee | `alpha>puts beta>puts error>puts` |
| 2 | Two callers, plus callee | `alpha>error>puts main>alpha>puts beta>error>puts main>beta>puts` |
| 3 | Three callers, plus callee | `main>alpha>error>puts main>alpha>puts main>beta>error>puts main>beta>puts` |

The upside of increasing the context sensitivity level is that more information can be gleaned from the CFG. For example, with context sensitivity of 1, the CFG will show that, when called from `alpha`, `puts` returns to `alpha`, when called from `error`, `puts` returns to `error`, and so forth. With context sensitivity of 0, the CFG simply shows that `puts` returns to `alpha`, `beta`, and `error`. This, specifically, is the context sensitivity level used in IDA. The downside of increasing the context sensitivity level is that it exponentially increases the analysis time.

## 4.2 Backward Slicing

A *program slice* is a subset of statements that is obtained from the original program, usually by removing zero or more statements. Slicing is often helpful in debugging and program understanding. For instance, it's usually easier to locate the source of a variable on a program slice.

A backward slice is constructed from a *target* in the program, and all data flows in this slice end at the *target*.

angr has a built-in analysis, called `BackwardSlice`, to construct a backward program slice. This section will act as a how-to for angr's `BackwardSlice` analysis, and followed by some in-depth discussion over the implementation choices and limitations.

### 4.2.1 First Step First

To build a `BackwardSlice`, you will need the following information as input.

- **Required** CFG. A control flow graph (CFG) of the program. This CFG must be an accurate CFG (CFGEmulated).
- **Required** Target, which is the final destination that your backward slice terminates at.
- **Optional** CDG. A control dependence graph (CDG) derived from the CFG. angr has a built-in analysis `CDG` for that purpose.
- **Optional** DDG. A data dependence graph (DDG) built on top of the CFG. angr has a built-in analysis `DDG` for that purpose.

A `BackwardSlice` can be constructed with the following code:

```
>>> import angr
# Load the project
>>> b = angr.Project("examples/fauxware/fauxware", load_options={"auto_load_libs": False}
↪)

# Generate a CFG first. In order to generate data dependence graph afterwards, you'll␣
↪have to:
# - keep all input states by specifying keep_state=True.
# - store memory, register and temporary values accesses by adding the angr.options.refs␣
↪option set.
# Feel free to provide more parameters (for example, context_sensitivity_level) for CFG
# recovery based on your needs.
>>> cfg = b.analyses.CFGEmulated(keep_state=True,
...                              state_add_options=angr.sim_options.refs,
...                              context_sensitivity_level=2)

# Generate the control dependence graph
>>> cdg = b.analyses.CDG(cfg)

# Build the data dependence graph. It might take a while. Be patient!
>>> ddg = b.analyses.DDG(cfg)

# See where we wanna go... let's go to the exit() call, which is modeled as a
# SimProcedure.
>>> target_func = cfg.kb.functions.function(name="exit")
# We need the CFGNode instance
>>> target_node = cfg.model.get_any_node(target_func.addr)

# Let's get a BackwardSlice out of them!
# ``targets`` is a list of objects, where each one is either a CodeLocation
# object, or a tuple of CFGNode instance and a statement ID. Setting statement
# ID to -1 means the very beginning of that CFGNode. A SimProcedure does not
# have any statement, so you should always specify -1 for it.
>>> bs = b.analyses.BackwardSlice(cfg, cdg=cdg, ddg=ddg, targets=[ (target_node, -1) ])
```

(continues on next page)

(continued from previous page)

```
# Here is our awesome program slice!
>>> print(bs)
```

Sometimes it's difficult to get a data dependence graph, or you may simply want build a program slice on top of a CFG. That's basically why DDG is an optional parameter. You can build a `BackwardSlice` solely based on CFG by doing:

```
>>> bs = b.analyses.BackwardSlice(cfg, control_flow_slice=True)
BackwardSlice (to [(<CFGNode exit (0x10000a0) [0]>, -1)])
```

### 4.2.2 Using The `BackwardSlice` Object

Before you go ahead and use `BackwardSlice` object, you should notice that the design of this class is fairly arbitrary right now, and it is still subject to change in the near future. We'll try our best to keep this documentation up-to-date.

#### Members

After construction, a `BackwardSlice` has the following members which describe a program slice:

| Member | Mode | Meaning |
|---|---|---|
| runs_in_slice | CFG-only | A `networkx.DiGraph` instance showing addresses of blocks and SimProcedures in the program slice, as well as transitions between them |
| cfg_nodes_in_ | CFG-only | A `networkx.DiGraph` instance showing CFGNodes in the program slice and transitions in between |
| chosen_statement | With DDG | A dict mapping basic block addresses to lists of statement IDs that are part of the program slice |
| chosen_exits | With DDG | A dict mapping basic block addresses to a list of "exits". Each exit in the list is a valid transition in the program slice |

Each "exit" in `chosen_exit` is a tuple including a statement ID and a list of target addresses. For example, an "exit" might look like the following:

```
(35, [ 0x400020 ])
```

If the "exit" is the default exit of a basic block, it'll look like the following:

```
("default", [ 0x400085 ])
```

#### Export an Annotated Control Flow Graph

## 4.3 Identifier

The identifier uses test cases to identify common library functions in CGC binaries. It prefilters by finding some basic information about stack variables/arguments. The information of about stack variables can be generally useful in other projects.

```
>>> import angr

# get all the matches
>>> p = angr.Project("../binaries/tests/i386/identifiable")
# note analysis is executed via the Identifier call
>>> idfer = p.analyses.Identifier()
>>> for funcInfo in idfer.func_info:
...     print(hex(funcInfo.addr), funcInfo.name)

0x8048e60 memcmp
0x8048ef0 memcpy
0x8048f60 memmove
0x8049030 memset
0x8049320 fdprintf
0x8049a70 sprintf
0x8049f40 strcasecmp
0x804a0f0 strcmp
0x804a190 strcpy
0x804a260 strlen
0x804a3d0 strncmp
0x804a620 strtol
0x804aa00 strtol
0x80485b0 free
0x804aab0 free
0x804aad0 free
```

(continues on next page)

(continued from previous page)

```

0x80485b0 free
```

## 4.4 angr Decompiler

### 4.4.1 Analysis Passes

| Name | Description | Sub-analysis |
|---|---|---|
| CFG recovery | Recover the control flow graph. | Indirect branch resolving |
| Indirect branch resolving | Resolve the targets of indirect branches. | Jump table resolving |
| Removing alignment blocks | | |
| Calling convention recovery | | |
| Stack pointer analysis | Determine values of stack pointer at each instruction. | |
| IR Lifting | Lift the original representation to AIL, block by block. | |
| AIL graph building | | |
| Rewriting single-target indirect branches | Replace single-target indirect branches with direct branches. | |
| Making return statements | Convert Ijk_Ret jump kinds into AIL Return statements. | |
| Simplifying AIL blocks | Simplify each AIL block. | Constant folding, copy propagation, dead assignment elimination, peephole optimizations |
| Reaching definition analysis | | |
| Constant folding | | |
| Copy propagation | | |
| Dead assignment elimination | | |
| Peephole optimizations | | |
| Simplifying AIL function | Simplify the entire AIL function. | Assignment expression folding, unifying local variables, call expression folding, reaching definition analysis |
| Assignment expression folding | Eliminate variables that are assigned to once and used once. | Copy propagation |
| Unifying local variables | Find local variables that are always equivalent and eliminate redundant copies. | Copy propagation |
| Call expression folding | Fold call expressions into the variable where its return value is stored. | Copy propagation |
| Call site building | Apply calling conventions to each call site and rewrite call statements to ones with arguments | Reaching definition analysis |
| Variable recovery | Identify local and global variables. | |
| Variable type inference | Collect type constraints and infer variable types. | |
| Simplification passes | | |
| Region identification | Identify single-entry, single-exit regions. | |
| Structure analysis | Structure each identified region to create high-level control flow structures. | |
| Code generation | | |

CHAPTER

FIVE

# ADVANCED TOPICS

## 5.1 Gotchas when using angr

This section contains a list of gotchas that users/victims of angr frequently run into.

### 5.1.1 SimProcedure inaccuracy

To make symbolic execution more tractable, angr replaces common library functions with summaries written in Python. We call these summaries SimProcedures. SimProcedures allow us to mitigate path explosion that would otherwise be introduced by, for example, `strlen` running on a symbolic string.

Unfortunately, our SimProcedures are far from perfect. If angr is displaying unexpected behavior, it might be caused by a buggy/incomplete SimProcedure. There are several things that you can do:

1. Disable the SimProcedure (you can exclude specific SimProcedures by passing options to the `angr.Project` class. This has the drawback of likely leading to a path explosion, unless you are very careful about constraining the input to the function in question. The path explosion can be partially mitigated with other angr capabilities (such as Veritesting).
2. Replace the SimProcedure with something written directly to the situation in question. For example, our `scanf` implementation is not complete, but if you just need to support a single, known format string, you can write a hook to do exactly that.
3. Fix the SimProcedure.

### 5.1.2 Unsupported syscalls

System calls are also implemented as SimProcedures. Unfortunately, there are system calls that we have not yet implemented in angr. There are several workarounds for an unsupported system call:

1. Implement the system call.

   **Todo**

   document this process

2. Hook the callsite of the system call (using `project.hook`) to make the required modifications to the state in an ad-hoc way.
3. Use the `state.posix.queued_syscall_returns` list to queue syscall return values. If a return value is queued, the system call will not be executed, and the value will be used instead. Furthermore, a function can be queued instead as the "return value", which will result in that function being applied to the state when the system call is triggered.

### 5.1.3 Symbolic memory model

The default memory model used by angr is inspired by Mayhem. This memory model supports limited symbolic reads and writes. If the memory index of a read is symbolic and the range of possible values of this index is too wide, the index is concretized to a single value. If the memory index of a write is symbolic at all, the index is concretized to a single value. This is configurable by changing the memory concretization strategies of `state.memory`.

### 5.1.4 Symbolic lengths

SimProcedures, and especially system calls such as `read()` and `write()` might run into a situation where the *length* of a buffer is symbolic. In general, this is handled very poorly: in many cases, this length will end up being concretized outright or retroactively concretized in later steps of execution. Even in cases when it is not, the source or destination file might end up looking a bit "weird".

### 5.1.5 Division by Zero

Z3 has some issues with divisions by zero. For example:

```
>>> z = z3.Solver()
>>> a = z3.BitVec('a', 32)
>>> b = z3.BitVec('b', 32)
>>> c = z3.BitVec('c', 32)
>>> z.add(a/b == c)
>>> z.add(b == 0)
>>> z.check()
>>> print(z.model().eval(b), z.model().eval(a/b))
0 4294967295
```

This makes it very difficult to handle certain situations in Claripy. We post-process the VEX IR itself to explicitly check for zero-divisions and create IRSB side-exits corresponding to the exceptional case, but SimProcedures and custom analysis code may let occurrences of zero divisions split through, which will then cause weird issues in your analysis. Be safe — when dividing, add a constraint against the denominator being zero.

## 5.2 Understanding the Execution Pipeline

If you've made it this far you know that at its core, angr is a highly flexible and intensely instrumentable emulator. In order to get the most mileage out of it, you'll want to know what happens at every step of the way when you say `simgr.run()`.

This is intended to be a more advanced document; you'll need to understand the function and intent of `SimulationManager`, `ExplorationTechnique`, `SimState`, and `SimEngine` in order to understand what we're talking about at times! You may want to have the angr source open to follow along with this.

At every step along the way, each function will take `**kwargs` and pass them along to the next function in the hierarchy, so you can pass parameters to any point in the hierarchy and they will trickle down to everything below.

### 5.2.1 Simulation Managers

So you've set your analysis in motion. Time to begin our journey.

#### `run()`

`SimulationManager.run()` takes several optional parameters, all of which control when to break out of the stepping loop. Notably, `n`, and `until`. `n` is used immediately - the run function loops, calling the `step()` function and passing on all its parameters until either `n` steps have happened or some other termination condition has occurred. If `n` is not provided, it defaults to 1, unless an `until` function is provided, in which case there will be no numerical cap on the

loop. Additionally, the stash that is being used is taken into consideration, as if it becomes empty execution must terminate.

So, in summary, when you call `run()`, `step()` will be called in a loop until any of the following:

1. The `n` number of steps have elapsed
2. The `until` function returns true
3. The exploration techniques `complete()` hooks (combined via the `SimulationManager.completion_mode` parameter/attribute - it is by default the `any` builtin function but can be changed to `all` for example) indicate that the analysis is complete
4. The stash being executed becomes empty

#### An aside: `explore()`

`SimulationManager.explore()` is a very thin wrapper around `run()` which adds the `Explorer` exploration technique, since performing one-off explorations is a very common action. Its code in its entirety is below:

```
num_find += len(self._stashes[find_stash]) if find_stash in self._stashes else 0
tech = self.use_technique(Explorer(find, avoid, find_stash, avoid_stash, cfg, num_find))

try:
    self.run(stash=stash, n=n, **kwargs)
finally:
    self.remove_technique(tech)

return self
```

### Exploration technique hooking

From here down, every function in the simulation manager can be instrumented by an exploration technique. The exact mechanism through which this works is that when you call `SimulationManager.use_technique()`, angr monkeypatches the simulation manager to replace any function implemented in the exploration technique's body with a function which will first call the exploration technique's function, and then on the second call will call the original function. This is somewhat messy to implement and certainly not thread safe by any means, but does produce a clean and powerful interface for exploration techniques to instrument stepping behavior, either before or after the original function is called, even choosing whether or not to call the original function whatsoever. Additionally, it allows multiple exploration techniques to hook the same function, as the monkeypatched function simply becomes the "original" function for the next-applied hook.

#### `step()`

There is a lot of complicated logic in `step()` to handle degenerate cases - mostly implementing the population of the `deadended` stash, the `save_unsat` option, and calling the `filter()` exploration technique hooks. Beyond this, though, most of the logic is looping through the stash specified by the `stash` argument and calling `step_state()` on each state, then applying the dict result of `step_state()` to the stash list. Finally, if the `step_func` parameter is provided, it is called with the simulation manager as a parameter before the step ends.

#### `step_state()`

The default `step_state()`, which can be overridden or instrumented by exploration techniques, is also simple - it calls `successors()`, which returns a `SimSuccessors` object, and then translates it into a dict mapping stash names to new states which should be added to that stash. It also implements error handling - if `successors()` throws an error, it will be caught and an `ErrorRecord` will be inserted into `SimulationManager.errored`.

#### successors()

We've almost made it out of SimulationManager. `successors()`, which can also be instrumented by exploration techniques, is supposed to take a state and step it forward, returning a `SimSuccessors` object categorizing its successors independently of any stash logic. If the `successor_func` parameter was provided, it is used and its return value is returned directly. If this parameter was not provided, we use the `project.factory.successors` method to tick the state forward and get our `SimSuccessors`.

### 5.2.2 The Engine

When we get to the actual successors generation, we need to figure out how to actually perform the execution. Hopefully, the angr documentation has been organized in a way such that by the time you reach this page, you know that a `SimEngine` is a device that knows how to take a state and produce its successors. There is only one "default engine" per project, but you can provide the `engine` parameter to specify which engine will be used to perform the step.

Keep in mind that this parameter can be provided way at the top, to `.step()`, `.explore()`, `.run()` or anything else that starts execution, and they will be filtered down to this level. Any additional parameters will continue being passed down, until they reach the part of the engine they are intended for. The engine will discard any parameters it doesn't understand.

Generally, the main entry point of an engine is `SimEngine.process()`, which can return whatever result it likes, but for simulation managers, engines are required to use `SuccessorsMixin`, which provides a `process()` method, which creates a `SimSuccessors` object and then calls `process_successors()` so that other mixins can fill it out.

angr's default engine, the `UberEngine`, contains several mixins which provide the `process_successors()` method:

- `SimEngineFailure` - handles stepping states with degenerate jumpkinds
- `SimEngineSyscall` - handles stepping states which have performed a syscall and need it executed
- `HooksMixin` - handles stepping states which have reached a hooked address and need the hook executed
- `SimEngineUnicorn` - executes machine code via the unicorn engine
- `SootMixin` - executes java bytecode via the SOOT IR
- `HeavyVEXMixin` - executes machine code via the VEX IR

Each of these mixins is implemented to fill out the `SimSuccessors` object if they can handle the current state, otherwise they call `super()` to pass the job on to the next class in the stack.

### 5.2.3 Engine mixins

`SimEngineFailure` handles error cases. It is only used when the previous jumpkind is one of `Ijk_EmFail`, `Ijk_MapFail`, `Ijk_Sig*`, `Ijk_NoDecode` (but only if the address is not hooked), or `Ijk_Exit`. In the first four cases, its action is to raise an exception. In the last case, its action is to simply produce no successors.

`SimEngineSyscall` services syscalls. It is used when the previous jumpkind is anything of the form `Ijk_Sys*`. It works by making a call into `SimOS` to retrieve the SimProcedure that should be run to respond to this syscall, and then running it! Pretty simple.

`HooksMixin` provides the hooking functionality in angr. It is used when a state is at an address that is hooked, and the previous jumpkind is *not* `Ijk_NoHook`. It simply looks up the associated SimProcedure and runs it on the state! It also takes the parameter `procedure`, which will cause the given procedure to be run for the current step even if the address is not hooked.

`SimEngineUnicorn` performs concrete execution with the Unicorn Engine. It is used when the state option `o.UNICORN` is enabled, and a myriad of other conditions designed for maximum efficiency (described below) are met.

`SootMixin` performs execution over the SOOT IR. Not very important unless you are analyzing java bytecode, in which case it is very important.

`SimEngineVEX` is the big fellow. It is used whenever any of the previous can't be used. It attempts to lift bytes from the current address into an IRSB, and then executes that IRSB symbolically. There are a huge number of parameters that can control this process, so it is best to reference the API doc for `angr.engines.vex.engine.SimEngineVEX.process()` describing them.

The exact process by which SimEngineVEX digs into an IRSB is a little complicated, but essentially it runs all the block's statements in order. This code is worth reading if you want to see the true inner core of angr's symbolic execution.

### 5.2.4 When using Unicorn Engine

If you add the `o.UNICORN` state option, at every step `SimEngineUnicorn` will be invoked, and try to see if it is allowed to use Unicorn to execute concretely.

What you REALLY want to do is to add the predefined set `o.unicorn` (lowercase) of options to your state:

```
unicorn = { UNICORN, UNICORN_SYM_REGS_SUPPORT, INITIALIZE_ZERO_REGISTERS, UNICORN_HANDLE_
↪TRANSMIT_SYSCALL }
```

These will enable some additional functionalities and defaults which will greatly enhance your experience. Additionally, there are a lot of options you can tune on the `state.unicorn` plugin.

A good way to understand how unicorn works is by examining the logging output (`logging.getLogger('angr.engines.unicorn_engine').setLevel('DEBUG'); logging.getLogger('angr.state_plugins.unicorn_engine').setLevel('DEBUG')` from a sample run of unicorn.

```
INFO    | 2017-02-25 08:19:48,012 | angr.state_plugins.unicorn | started emulation at␣
↪0x4012f9 (1000000 steps)
```

Here, angr diverts to unicorn engine, beginning with the basic block at 0x4012f9. The maximum step count is set to 1000000, so if execution stays in Unicorn for 1000000 blocks, it'll automatically pop out. This is to avoid hanging in an infinite loop. The block count is configurable via the `state.unicorn.max_steps` variable.

```
INFO    | 2017-02-25 08:19:48,014 | angr.state_plugins.unicorn | mmap [0x401000,␣
↪0x401fff], 5 (symbolic)
INFO    | 2017-02-25 08:19:48,016 | angr.state_plugins.unicorn | mmap [0x7fffffffffe0000,
↪ 0x7fffffffffeffff], 3 (symbolic)
INFO    | 2017-02-25 08:19:48,019 | angr.state_plugins.unicorn | mmap [0x6010000,␣
↪0x601ffff], 3
INFO    | 2017-02-25 08:19:48,022 | angr.state_plugins.unicorn | mmap [0x602000,␣
↪0x602fff], 3 (symbolic)
INFO    | 2017-02-25 08:19:48,023 | angr.state_plugins.unicorn | mmap [0x400000,␣
↪0x400fff], 5
INFO    | 2017-02-25 08:19:48,025 | angr.state_plugins.unicorn | mmap [0x7000000,␣
↪0x7000fff], 5
```

angr performs lazy mapping of data that is accessed by unicorn engine, as it is accessed. 0x401000 is the page of instructions that it is executing, 0x7fffffffffe0000 is the stack, and so on. Some of these pages are symbolic, meaning that they contain at least some data that, when accessed, will cause execution to abort out of Unicorn.

```
INFO    | 2017-02-25 08:19:48,037 | angr.state_plugins.unicorn | finished emulation at␣
↪0x7000080 after 3 steps: STOP_STOPPOINT
```

Execution stays in Unicorn for 3 basic blocks (a computational waste, considering the required setup), after which it reaches a simprocedure location and jumps out to execute the simproc in angr.

```
INFO    | 2017-02-25 08:19:48,076 | angr.state_plugins.unicorn | started emulation at␣
↪0x40175d (1000000 steps)
INFO    | 2017-02-25 08:19:48,077 | angr.state_plugins.unicorn | mmap [0x401000,␣
↪0x401fff], 5 (symbolic)
INFO    | 2017-02-25 08:19:48,079 | angr.state_plugins.unicorn | mmap [0x7fffffffffe0000,
↪ 0x7fffffffffefffff], 3 (symbolic)
INFO    | 2017-02-25 08:19:48,081 | angr.state_plugins.unicorn | mmap [0x6010000,␣
↪0x601ffff], 3
```

After the simprocedure, execution jumps back into Unicorn.

```
WARNING | 2017-02-25 08:19:48,082 | angr.state_plugins.unicorn | fetching empty page␣
↪[0x0, 0xfff]
INFO    | 2017-02-25 08:19:48,103 | angr.state_plugins.unicorn | finished emulation at␣
↪0x401777 after 1 steps: STOP_EXECNONE
```

Execution bounces out of Unicorn almost right away because the binary accessed the zero-page.

```
INFO    | 2017-02-25 08:19:48,120 | angr.engines.unicorn_engine | not enough runs since␣
↪last unicorn (100)
INFO    | 2017-02-25 08:19:48,125 | angr.engines.unicorn_engine | not enough runs since␣
↪last unicorn (99)
```

To avoid thrashing in and out of Unicorn (which is expensive), we have cooldowns (attributes of the `state.unicorn` plugin) that wait for certain conditions to hold (i.e., no symbolic memory accesses for X blocks) before jumping back into unicorn when a unicorn run is aborted due to anything but a simprocedure or syscall. Here, the condition it's waiting for is for 100 blocks to be executed before jumping back in.

## 5.3 What's Up With Mixins, Anyway?

If you are trying to work more intently with the deeper parts of angr, you will need to understand one of the design patterns we use frequently: the mixin pattern.

In brief, the mixin pattern is where Python's subclassing features is used not to implement IS-A relationships (a Child is a kind of Person) but instead to implement pieces of functionality for a type in different classes to make more modular and maintainable code. Here's an example of the mixin pattern in action:

```
class Base:
    def add_one(self, v):
        return v + 1

class StringsMixin(Base):
    def add_one(self, v):
        coerce = type(v) is str
        if coerce:
            v = int(v)
        result = super().add_one(v)
        if coerce:
            result = str(result)
        return result

class ArraysMixin(Base):
    def add_one(self, v):
```

(continues on next page)

(continued from previous page)

```
        if type(v) is list:
            return [super().add_one(v_x) for v_x in v]
        else:
            return super().add_one(v)

class FinalClass(ArraysMixin, StringsMixin, Base):
    pass
```

With this construction, we are able to define a very simple interface in the `Base` class, and by "mixing in" two mixins, we can create the `FinalClass` which has the same interface but with additional features. This is accomplished through Python's powerful multiple inheritance model, which handles method dispatch by creating a *method resolution order*, or MRO, which is unsurprisingly a list which determines the order in which methods are called as execution proceeds through `super()` calls. You can view a class' MRO as such:

```
FinalClass.__mro__

(FinalClass, ArraysMixin, StringsMixin, Base, object)
```

This means that when we take an instance of `FinalClass` and call `add_one()`, Python first checks to see if `FinalClass` defines an `add_one`, and then `ArraysMixin`, and so on and so forth. Furthermore, when `ArraysMixin` calls `super().add_one()`, Python will skip past `ArraysMixin` in the MRO, first checking if `StringsMixin` defines an `add_one`, and so forth.

Because multiple inheritance can create strange dependency graphs in the subclass relationship, there are rules for generating the MRO and for determining if a given mix of mixins is even allowed. This is important to understand when building complex classes with many mixins which have dependencies on each other. In short: left-to-right, depth-first, but deferring any base classes which are shared by multiple subclasses (the merge point of a diamond pattern in the inheritance graph) until the last point where they would be encountered in this depth-first search. For example, if you have classes A, B(A), C(B), D(A), E(C, D), then the method resolution order will be E, C, B, D, A. If there is any case in which the MRO would be ambiguous, the class construction is illegal and will throw an exception at import time.

This is complicated! If you find yourself confused, the canonical document explaining the rationale, history, and mechanics of Python's multiple inheritance can be found here.

### 5.3.1 Mixins in Claripy Solvers

**Todo**

Write this section

### 5.3.2 Mixins in angr Engines

The main entry point to a SimEngine is `process()`, but how do we determine what that does?

The mixin model is used in SimEngine and friends in order to allow pieces of functionality to be reused between static and symbolic analyses. The default engine, `UberEngine`, is defined as follows:

```
class UberEngine(SimEngineFailure,
   SimEngineSyscall,
   HooksMixin,
   SimEngineUnicorn,
   SuperFastpathMixin,
```

(continues on next page)

(continued from previous page)

```
    TrackActionsMixin,
    SimInspectMixin,
    HeavyResilienceMixin,
    SootMixin,
    HeavyVEXMixin
):
    pass
```

Each of these mixins provides either execution through a different medium or some additional instrumentation feature. Though they are not listed here explicitly, there are some base classes implicit to this hierarchy which set up the way this class is traversed. Most of these mixins inherit from `SuccessorsMixin`, which is what provides the basic `process()` implementation. This function sets up the `SimSuccessors` for the rest of the mixins to fill in, and then calls `process_successors()`, which each of the mixins which provide some mode of execution implement. If the mixin can handle the step, it does so and returns, otherwise it calls `super().process_successors()`. In this way, the MRO for the engine class determines what the order of precedence for the engine's pieces is.

### HeavyVEXMixin and friends

Let's take a closer look at the last mixin, `HeavyVEXMixin`. If you look at the module hierarchy of the angr `engines` submodule, you will see that the `vex` submodule has a lot of pieces in it which are organized by how tightly tied to particular state types or data types they are. The heavy VEX mixin is one version of the culmination of all of these. Let's look at its definition:

```
class HeavyVEXMixin(SuccessorsMixin, ClaripyDataMixin, SimStateStorageMixin, VEXMixin,␣
↪VEXLifter):
    ...
    # a WHOLE lot of implementation
```

So, the heavy VEX mixin is meant to provide fully instrumented symbolic execution on a SimState. What does this entail? The mixins tell the tale.

First, the plain `VEXMixin`. This mixin is designed to provide the barest-bones framework for processing a VEX block. Take a look at its source code. Its main purpose is to perform the preliminary digestion of the VEX IRSB and dispatch processing of it to methods which are provided by mixins - look at the methods which are either `pass` or `return NotImplemented`. Notice that absolutely none of its code makes any assumption whatsoever of what the type of `state` is or even what the type of the data words inside `state` are. This job is delegated to other mixins, making the `VEXMixin` an appropriate base class for literally any analysis on VEX blocks.

The next-most interesting mixin is the `ClaripyDataMixin`, whose source code is here. This mixin actually integrates the fact that we are executing over the domain of Claripy ASTs. It does this by implementing some of the methods which are unimplemented in the `VEXMixin`, most importantly the `ITE` expression, all the operations, and the clean helpers.

In terms of what it looks like to actually touch the SimState, the `SimStateStorageMixin` provides the glue between the `VEXMixin`'s interface for memory writes et al and SimState's interface for memory writes and such. It is unremarkable, except for a small interaction between it and the `ClaripyDataMixin`. The Claripy mixin also overrides the memory/register read/write functions, for the purpose of converting between the bitvector and floating-point types, since the vex interface expects to be able to load and store floats, but the SimState interface wants to load and store only bitvectors. Because of this, *the claripy mixin must come before the storage mixin in the MRO*. This is very much an interaction like the one in the add_one example at the start of this page - one mixin serves as a data filtering layer for another mixin.

#### Instrumenting the data layer

Let's turn our attention to a mixin which is not included in the `HeavyVEXMixin` but rather mixed into the `UberEngine` formula explicitly: the `TrackActionsMixin`. This mixin implements "SimActions", which is angr parlance for dataflow tracking. Again, look at the source code. The way it does this is that it *wraps and unwraps the data layer* to pass around additional information about data flows. Look at how it instruments `RdTmp`, for instance. It immediately `super()`-calls to the next method in the MRO, but instead of returning that data it returns a tuple of the data and its dependencies, which depending on whether you want temporary variables to be atoms in the dataflow model, will either be just the tmp which was read or the dependencies of the value written to that tmp.

This pattern continues for every single method that this mixin touches - any expression it receives must be unpacked into the expression and its dependencies, and any result must be packaged with its dependencies before it is returned. This works because the mixin above it makes no assumptions about what data it is passing around, and the mixin below it never gets to see any dependencies whatsoever. In fact, there could be multiple mixins performing this kind of wrap-unwrap trick and they could all coexist peacefully!

Note that a mixin which instruments the data layer in this way is *obligated* to override *every single method which takes or returns an expression value*, even if it doesn't perform any operation on the expression other than doing the wrapping and unwrapping. To understand why, imagine that the mixin does not override the `handle_vex_const` expression, so immediate value loads are not annotated with dependencies. The expression value which will be returned from the mixin which does provide `handle_vex_const` will not be a tuple of (expression, deps), it will just be the expression. Imagine this execution is taking place in the context of a `WrTmp(t0, Const(0))`. The const expression will be passed down to the `WrTmp` handler along with the identifier of the tmp to write to. However, since `handle_vex_stmt_WrTmp` *will* be overridden by our mixin which touches the data layer, it expects to be passed the tuple including the deps, and so it will crash when trying to unpack the not-a-tuple value.

In this way, you can sort of imagine that a mixin which instruments the data layer in this way is actually creating a contract within Python's nonexistent typesystem - you are guaranteed to receive back any types you return, but you must pass down any types you receive as return values from below.

### 5.3.3 Mixins in the memory model

**Todo**

write this section

## 5.4 Optimization considerations

The performance of angr as an analysis tool or emulator is greatly handicapped by the fact that lots of it is written in Python. Regardless, there are a lot of optimizations and tweaks you can use to make angr faster and lighter.

### 5.4.1 General speed tips

- *Use pypy*. Pypy is an alternate Python interpreter that performs optimized jitting of Python code. In our tests, it's a 10x speedup out of the box.
- *Only use the SimEngine mixins that you need*. SimEngine uses a mixin model which allows you to add and remove features by constructing new classes. The default engine mixes in every possible features, and the consequence of that is that it is slower than it needs to be. Look at the definition for `UberEngine` (the default SimEngine), copy its declaration, and remove all the base classes which provide features you don't need.
- *Don't load shared libraries unless you need them*. The default setting in angr is to try at all costs to find shared libraries that are compatible with the binary you've loaded, including loading them straight out of your OS libraries. This can complicate things in a lot of scenarios. If you're performing an analysis that's anything more abstract than bare-bones symbolic execution, ESPECIALLY control-flow graph construction, you might want

to make the tradeoff of sacrificing accuracy for tractability. angr does a reasonable job of making sane things happen when library calls to functions that don't exist try to happen.

- *Use hooking and SimProcedures*. If you're enabling shared libraries, then you definitely want to have SimProcedures written for any complicated library function you're jumping into. If there's no autonomy requirement for this project, you can often isolate individual problem spots where analysis hangs up and summarize them with a hook.
- *Use SimInspect*. *SimInspect* is the most underused and one of the most powerful features of angr. You can hook and modify almost any behavior of angr, including memory index resolution (which is often the slowest part of any angr analysis).
- *Write a concretization strategy*. A more powerful solution to the problem of memory index resolution is a concretization strategy.
- *Use the Replacement Solver*. You can enable it with the `angr.options.REPLACEMENT_SOLVER` state option. The replacement solver allows you to specify AST replacements that are applied at solve-time. If you add replacements so that all symbolic data is replaced with concrete data when it comes time to do the solve, the runtime is greatly reduced. The API for adding a replacement is `state.se._solver.add_replacement(old, new)`. The replacement solver is a bit finicky, so there are some gotchas, but it'll definitely help.

### 5.4.2 If you're performing lots of concrete or partially-concrete execution

- *Use the unicorn engine*. If you have unicorn engine installed, angr can be built to take advantage of it for concrete emulation. To enable it, add the options in the set `angr.options.unicorn` to your state. Keep in mind that while most items under `angr.options` are individual options, `angr.options.unicorn` is a bundle of options, and is thus a set. *NOTE*: At time of writing the official version of unicorn engine will not work with angr - we have a lot of patches to it to make it work well with angr. They're all pending pull requests at this time, so sit tight. If you're really impatient, ping us about uploading our fork!
- *Enable fast memory and fast registers*. The state options `angr.options.FAST_MEMORY` and `angr.options.FAST_REGISTERS` will do this. These will switch the memory/registers over to a less intensive memory model that sacrifices accuracy for speed. TODO: document the specific sacrifices. Should be safe for mostly concrete access though. NOTE: not compatible with concretization strategies.
- *Concretize your input ahead of time*. This is the approach taken by driller. When creating a state with `entry_state` or the like, you can create a SimFile filled with symbolic data, pass it to the initialization function as an argument `entry_state(..., stdin=my_simfile)`, and then constrain the symbolic data in the SimFile to what you want the input to be. If you don't require any tracking of the data coming from stdin, you can forego the symbolic part and just fill it with concrete data. If there are other sources of input besides standard input, do the same for those.
- *Use the afterburner*. While using unicorn, if you add the `UNICORN_THRESHOLD_CONCRETIZATION` state option, angr will accept thresholds after which it causes symbolic values to be concretized so that execution can spend more time in Unicorn. Specifically, the following thresholds exist:
  - `state.unicorn.concretization_threshold_memory` - this is the number of times a symbolic variable, stored in memory, is allowed to kick execution out of Unicorn before it is forcefully concretized and forced into Unicorn anyways.
  - `state.unicorn.concretization_threshold_registers` - this is the number of times a symbolic variable, stored in a register, is allowed to kick execution out of Unicorn before it is forcefully concretized and forced into Unicorn anyways.
  - `state.unicorn.concretization_threshold_instruction` - this is the number of times that any given instruction can force execution out of Unicorn (by running into symbolic data) before any symbolic data encountered at that instruction is concretized to force execution into Unicorn.

  You can get further control of what is and isn't concretized with the following sets:

- `state.unicorn.always_concretize` - a set of variable names that will always be concretized to force execution into unicorn (in fact, the memory and register thresholds just end up causing variables to be added to this list).
- `state.unicorn.never_concretize` - a set of variable names that will never be concretized and forced into Unicorn under any condition.
- `state.unicorn.concretize_at` - a set of instruction addresses at which data should be concretized and forced into Unicorn. The instruction threshold causes addresses to be added to this set.

Once something is concretized with the afterburner, you will lose track of that variable. The state will still be consistent, but you'll lose dependencies, as the stuff that comes out of Unicorn is just concrete bits with no memory of what variables they came from. Still, this might be worth it for the speed in some cases, if you know what you want to (or do not want to) concretize.

### 5.4.3 Memory optimization

The golden rule for memory optimization is to make sure you're not keeping any references to data you don't care about anymore, especially related to states which have been left behind. If you find yourself running out of memory during analysis, the first thing you want to do is make sure you haven't caused a state explosion, meaning that the analysis is accumulating program states too quickly. If the state count is in control, then you can start looking for reference leaks. A good tool to do this with is https://github.com/rhelmot/dumpsterdiver, which gives you an interactive prompt for exploring the reference graph of a Python process.

One specific consideration that should be made when analyzing programs with very long paths is that the state history is designed to accumulate data infinitely. This is less of a problem than it could be because the data is stored in a smart tree structure and never copied, but it will accumulate infinitely. To downsize a state's history and free all data related to old steps, call `state.history.trim()`.

One *particularly* problematic member of the history dataset is the basic block trace and the stack pointer trace. When using unicorn engine, these lists of ints can become huge very very quickly. To disable unicorn's capture of ip and sp data, remove the state options `UNICORN_TRACK_BBL_ADDRS` and `UNICORN_TRACK_STACK_POINTERS`.

## 5.5 Working with File System, Sockets, and Pipes

It's very important to be able to control the environment that emulated programs see, including how symbolic data is introduced from the environment! angr has a robust series of abstractions to help you set up the environment you want.

The root of any interaction with the filesystem, sockets, pipes, or terminals is a SimFile object. A SimFile is a *storage* abstraction that defines a sequence of bytes, symbolic or otherwise. There are several kinds of SimFiles which store their data very differently - the two easiest examples are `SimFile` (the base class is actually called `SimFileBase`), which stores files as a flat address-space of data, and `SimPackets`, which stores a sequence of variable-sized reads. The former is best for modeling programs that need to perform seeks on their files, and is the default storage for opened files, while the latter is best for modeling programs that depend on short-reads or use scanf, and is the default storage for stdin/stdout/stderr.

Because SimFiles can have such diverse storage mechanisms, the interface for interacting with them is *very* abstracted. You can read from the file from some position, you can write to the file at some position, you can ask how many bytes are currently stored in the file, and you can concretize the file, generating a testcase for it. If you know specifically which SimFile class you're working with, you can take much more powerful control over it, and as a result you're encouraged to manually create any files you want to work with when you create your initial state.

Specifically, each SimFile class creates its own abstraction of a "position" within the file - each read and write takes a position and returns a new position that you should use to continue from where you left off. If you're working with SimFiles of unknown type you have to treat this position as a totally opaque object with no semantics other than the contract with the read/write functions.

However! This is a very poor match to how programs generally interact with files, so angr also has a SimFileDescriptor abstraction, which provides the familiar read/write/seek/tell interfaces but will also return error conditions when the underlying storage don't support the appropriate operations - just like normal file descriptors!

You may access the mapping from file descriptor number to file descriptor object in `state.posix.fd`. See the API document for *angr.storage.file.SimFileDescriptorBase* for more details.

### 5.5.1 Just tell me how to do what I want to do!

Okay okay!!

To create a SimFile, you should just create an instance of the class you want to use. Refer to *angr.storage.file* for the full instructions.

Let's go through a few illustrative examples, which cover how you can work with a concrete file, a symbolic file, a file with mixed concrete and symbolic content, or streams.

#### Example 1: Create a file with concrete content

```
>>> import angr
>>> simfile = angr.SimFile('myconcretefile', content='hello world!\n')
```

Here's a nuance - you can't use SimFiles without a state attached, because reasons. You'll **never** have to do this in a real scenario (this operation happens automatically when you pass a SimFile into a constructor or the filesystem) but let's mock it up:

```
>>> proj = angr.Project('/bin/true')
>>> state = proj.factory.blank_state()
>>> simfile.set_state(state)
```

To demonstrate the behavior of these files we're going to use the fact that the default SimFile position is just the number of bytes from the start of the file. `SimFile.read` returns a tuple (bitvector data, actual size, new pos):

```
>>> data, actual_size, new_pos = simfile.read(0, 5)
>>> from angr import claripy
>>> assert claripy.is_true(data == 'hello')
>>> assert claripy.is_true(actual_size == 5)
>>> assert claripy.is_true(new_pos == 5)
```

Continue the read, trying to read way too much:

```
>>> data, actual_size, new_pos = simfile.read(new_pos, 1000)
```

angr doesn't try to sanitize the data returned, only the size - we returned 1000 bytes! The intent is that you're only allowed to use up to actual_size of them.

```
>>> assert len(data) == 1000*8  # bitvector sizes are in bits
>>> assert claripy.is_true(actual_size == 8)
>>> assert claripy.is_true(data.get_bytes(0, 8) == ' world!\n')
>>> assert claripy.is_true(new_pos == 13)
```

#### Example 2: Create a file with symbolic content and a defined size

```
>>> simfile = angr.SimFile('mysymbolicfile', size=0x20)
>>> simfile.set_state(state)
```

(continues on next page)

(continued from previous page)

```
>>> data, actual_size, new_pos = simfile.read(0, 0x30)
>>> assert data.symbolic
>>> assert claripy.is_true(actual_size == 0x20)
```

The basic SimFile provides the same interface as `state.memory`, so you can load data directly:

```
>>> assert simfile.load(0, actual_size) is data.get_bytes(0, 0x20)
```

### Example 3: Create a file with constrained symbolic content

```
>>> bytes_list = [claripy.BVS('byte_%d' % i, 8) for i in range(32)]
>>> bytes_ast = claripy.Concat(*bytes_list)
>>> mystate = proj.factory.entry_state(stdin=angr.SimFile('/dev/stdin', content=bytes_
↪ast))
>>> for byte in bytes_list:
...     mystate.solver.add(byte >= 0x20)
...     mystate.solver.add(byte <= 0x7e)
```

### Example 4: Create a file with some mixed concrete and symbolic content, but no EOF

```
>>> variable = claripy.BVS('myvar', 10*8)
>>> simfile = angr.SimFile('mymixedfile', content=variable.concat(claripy.BVV('\n')),␣
↪has_end=False)
>>> simfile.set_state(state)
```

We can always query the number of bytes stored in the file:

```
>>> assert claripy.is_true(simfile.size == 11)
```

Reads will generate additional symbolic data past the current frontier:

```
>>> data, actual_size, new_pos = simfile.read(0, 15)
>>> assert claripy.is_true(actual_size == 15)
>>> assert claripy.is_true(new_pos == 15)

>>> assert claripy.is_true(data.get_bytes(0, 10) == variable)
>>> assert claripy.is_true(data.get_bytes(10, 1) == '\n')
>>> assert data.get_bytes(11, 4).symbolic
```

### Example 5: Create a file with a symbolic size (`has_end` is implicitly true here)

```
>>> symsize = claripy.BVS('mysize', 64)
>>> state.solver.add(symsize >= 10)
>>> state.solver.add(symsize < 20)
>>> simfile = angr.SimFile('mysymsizefile', size=symsize)
>>> simfile.set_state(state)
```

Reads will encode all possibilities:

```
>>> data, actual_size, new_pos = simfile.read(0, 30)
>>> assert set(state.solver.eval_upto(actual_size, 30)) == set(range(10, 20))
```

The maximum size can't be easily resolved, so the data returned is 30 bytes long, and we're supposed to use it conjunction with actual_size.

```
>>> assert len(data) == 30*8
```

Symbolic read sizes work too!

```
>>> symreadsize = claripy.BVS('myreadsize', 64)
>>> state.solver.add(symreadsize >= 5)
>>> state.solver.add(symreadsize < 30)
>>> data, actual_size, new_pos = simfile.read(0, symreadsize)
```

All sizes between 5 and 20 should be possible:

```
>>> assert set(state.solver.eval_upto(actual_size, 30)) == set(range(5, 20))
```

### Example 6: Working with streams (SimPackets)

So far, we've only used the SimFile class, which models a random-accessible file object. However, in real life, files are not everything. Streams (standard I/O, TCP, etc.) are a great example: While they hold data like a normal file does, they do not support random accesses, e.g., you cannot read out the second byte of stdin if you have already read passed that position, and you cannot modify any byte that has been previously sent out to a network endpoint. This allows us to design a simpler abstraction for streams in angr.

Believe it or not, this simpler abstraction for streams will benefit symbolic execution. Consider an example program that calls `scanf` N times to read in N strings. With a traditional SimFile, as we do not know the length of each input string, there does not exist any clear boundary in the file between these symbolic input strings. In this case, angr will perform N symbolic reads where each read will generate a gigantic tree of claripy ASTs, with string lengths being symbolic. This is a nightmare for constraint solving. Nevertheless, the fact that `scanf` is used on a stream (stdin) dictates that there will be zero overlap between individual reads, regardless of the sizes of each symbolic input string. We may as well model stdin as a stream that comprises of *consecutive packets*, instead of a file containing a sequence of bytes. Each of the packet can be of a fixed length or a symbolic length. Since there will be absolutely no byte overlap between packets, the constraints that angr will produce after executing this example program will be a lot simpler.

The key concept involved is "short reads", i.e. when you ask for `n` bytes but actually get back fewer bytes than that. We use a different class implementing SimFileBase, `SimPackets`, to automatically enable support for short reads. By default, stdin, stdout, and stderr are all SimPackets objects.

```
>>> simfile = angr.SimPackets('mypackets')
>>> simfile.set_state(state)
```

This'll just generate a single packet. For SimPackets, the position is just a packet number! If left unspecified, short_reads is determined from a state option.

```
>>> data, actual_size, new_pos = simfile.read(0, 20, short_reads=True)
>>> assert len(data) == 20*8
>>> assert set(state.solver.eval_upto(actual_size, 30)) == set(range(21))
```

Data in a SimPackets is stored as tuples of (packet data, packet size) in `.content`.

```
>>> print(simfile.content)
[(<BV160 packet_0_mypackets>, <BV64 packetsize_0_mypackets>)]

>>> simfile.read(0, 1, short_reads=False)
>>> print(simfile.content)
```

(continues on next page)

(continued from previous page)

```
[(<BV160 packet_0_mypackets>, <BV64 packetsize_0_mypackets>), (<BV8 packet_1_mypackets>,
↪<BV64 0x1>)]
```

So hopefully you understand sort of the kind of data that a SimFile can store and what'll happen when a program tries to interact with it with various combinations of symbolic and concrete data. Those examples only covered reads, but writes are pretty similar.

### 5.5.2 The filesystem, for real now

If you want to make a SimFile available to the program, we need to either stick it in the filesystem or serve stdin/stdout from it.

The simulated filesystem is the `state.fs` plugin. You can store, load, and delete files from the filesystem, with the `insert`, `get`, and `delete` methods. Refer to *angr.state_plugins.filesystem* for details.

So to make our file available as `/tmp/myfile`:

```
>>> state.fs.insert('/tmp/myfile', simfile)
>>> assert state.fs.get('/tmp/myfile') is simfile
```

Then, after execution, we would extract the file from the result state and use `simfile.concretize()` to generate a testcase to reach that state. Keep in mind that `concretize()` returns different types depending on the file type - for a SimFile it's a bytestring and for SimPackets it's a list of bytestrings.

The simulated filesystem supports a fun concept of "mounts", where you can designate a subtree as instrumented by a particular provider. The most common mount is to expose a part of the host filesystem to the guest, lazily importing file data when the program asks for it:

```
>>> state.fs.mount('/', angr.SimHostFilesystem('./guest_chroot'))
```

You can write whatever kind of mount you want to instrument filesystem access by subclassing `angr.SimMount`!

The filesystem also has a root directory, which `state.fs.chroot` changes - this is what the `chroot` simprocedure calls. The new root is resolved inside the filesystem the state already has, so a guest calling `chroot` can only reduce what it is able to reach; it never gains access to anything you did not mount yourself.

### 5.5.3 Stdio streams

For stdin and friends, it's a little more complicated. The relevant plugin is `state.posix`, which stores all abstractions relevant to a POSIX-compliant environment. You can always get a state's stdin SimFile with `state.posix.stdin`, but you can't just replace it - as soon as the state is created, references to this file are created in the file descriptors. Because of this you need to specify it at the time the POSIX plugin is created:

```
>>> state.register_plugin('posix', angr.state_plugins.posix.SimSystemPosix(stdin=simfile,
↪ stdout=simfile, stderr=simfile))
>>> assert state.posix.stdin is simfile
>>> assert state.posix.stdout is simfile
>>> assert state.posix.stderr is simfile
```

Or, there's a nice shortcut while creating the state if you only need to specify stdin:

```
>>> state = proj.factory.entry_state(stdin=simfile)
>>> assert state.posix.stdin is simfile
```

Any of those places you can specify a SimFileBase, you can also specify a string or a bitvector (a flat SimFile with fixed size will be created to hold it) or a SimFile type (it'll be instantiated for you).

## 5.6 Intermediate Representation

In order to be able to analyze and execute machine code from different CPU architectures, such as MIPS, ARM, and PowerPC in addition to the classic x86, angr performs most of its analysis on an *intermediate representation*, a structured description of the fundamental actions performed by each CPU instruction. By understanding angr's IR, VEX (which we borrowed from Valgrind), you will be able to write very quick static analyses and have a better understanding of how angr works.

The VEX IR abstracts away several architecture differences when dealing with different architectures, allowing a single analysis to be run on all of them:

- **Register names.** The quantity and names of registers differ between architectures, but modern CPU designs hold to a common theme: each CPU contains several general purpose registers, a register to hold the stack pointer, a set of registers to store condition flags, and so forth. The IR provides a consistent, abstracted interface to registers on different platforms. Specifically, VEX models the registers as a separate memory space, with integer offsets (e.g., AMD64's `rax` is stored starting at address 16 in this memory space).
- **Memory access.** Different architectures access memory in different ways. For example, ARM can access memory in both little-endian and big-endian modes. The IR abstracts away these differences.
- **Memory segmentation.** Some architectures, such as x86, support memory segmentation through the use of special segment registers. The IR understands such memory access mechanisms.
- **Instruction side-effects.** Most instructions have side-effects. For example, most operations in Thumb mode on ARM update the condition flags, and stack push/pop instructions update the stack pointer. Tracking these side-effects in an *ad hoc* manner in the analysis would be crazy, so the IR makes these effects explicit.

There are lots of choices for an IR. We use VEX, since the uplifting of binary code into VEX is quite well supported. VEX is an architecture-agnostic, side-effects-free representation of a number of target machine languages. It abstracts machine code into a representation designed to make program analysis easier. This representation has four main classes of objects:

- **Expressions.** IR Expressions represent a calculated or constant value. This includes memory loads, register reads, and results of arithmetic operations.
- **Operations.** IR Operations describe a *modification* of IR Expressions. This includes integer arithmetic, floating-point arithmetic, bit operations, and so forth. An IR Operation applied to IR Expressions yields an IR Expression as a result.
- **Temporary variables.** VEX uses temporary variables as internal registers: IR Expressions are stored in temporary variables between use. The content of a temporary variable can be retrieved using an IR Expression. These temporaries are numbered, starting at `t0`. These temporaries are strongly typed (e.g., "64-bit integer" or "32-bit float").
- **Statements.** IR Statements model changes in the state of the target machine, such as the effect of memory stores and register writes. IR Statements use IR Expressions for values they may need. For example, a memory store *IR Statement* uses an *IR Expression* for the target address of the write, and another *IR Expression* for the content.
- **Blocks.** An IR Block is a collection of IR Statements, representing an extended basic block (termed "IR Super Block" or "IRSB") in the target architecture. A block can have several exits. For conditional exits from the middle of a basic block, a special *Exit* IR Statement is used. An IR Expression is used to represent the target of the unconditional exit at the end of the block.

VEX IR is actually quite well documented in the `libvex_ir.h` file (https://github.com/angr/vex/blob/master/pub/libvex_ir.h) in the VEX repository. For the lazy, we'll detail some parts of VEX that you'll likely interact with fairly frequently. To begin with, here are some IR Expressions:

| IR Expression | Evaluated Value | VEX Output Example |
|---|---|---|
| Constant | A constant value. | 0x4:I32 |
| Read Temp | The value stored in a VEX temporary variable. | RdTmp(t10) |
| Get Register | The value stored in a register. | GET:I32(16) |
| Load Memory | The value stored at a memory address, with the address specified by another IR Expression. | LDle:I32 / LDbe:I64 |
| Operation | A result of a specified IR Operation, applied to specified IR Expression arguments. | Add32 |
| If-Then-Else | If a given IR Expression evaluates to 0, return one IR Expression. Otherwise, return another. | ITE |
| Helper Function | VEX uses C helper functions for certain operations, such as computing the conditional flags registers of certain architectures. These functions return IR Expressions. | function_name() |

These expressions are then, in turn, used in IR Statements. Here are some common ones:

| IR Statement | Meaning | VEX Output Example |
|---|---|---|
| Write Temp | Set a VEX temporary variable to the value of the given IR Expression. | WrTmp(t1) = (IR Expression) |
| Put Register | Update a register with the value of the given IR Expression. | PUT(16) = (IR Expression) |
| Store Memory | Update a location in memory, given as an IR Expression, with a value, also given as an IR Expression. | STle(0x1000) = (IR Expression) |
| Exit | A conditional exit from a basic block, with the jump target specified by an IR Expression. The condition is specified by an IR Expression. | if (condition) goto (Boring) 0x4000A00:I32 |

An example of an IR translation, on ARM, is produced below. In the example, the subtraction operation is translated into a single IR block comprising 5 IR Statements, each of which contains at least one IR Expression (although, in real life, an IR block would typically consist of more than one instruction). Register names are translated into numerical indices given to the *GET* Expression and *PUT* Statement. The astute reader will observe that the actual subtraction is modeled by the first 4 IR Statements of the block, and the incrementing of the program counter to point to the next instruction (which, in this case, is located at `0x59FC8`) is modeled by the last statement.

The following ARM instruction:

```
subs R2, R2, #8
```

Becomes this VEX IR:

```
t0 = GET:I32(16)
t1 = 0x8:I32
```

(continues on next page)

(continued from previous page)

```
t3 = Sub32(t0,t1)
PUT(16) = t3
PUT(68) = 0x59FC8:I32
```

Now that you understand VEX, you can actually play with some VEX in angr: We use a library called PyVEX that exposes VEX into Python. In addition, PyVEX implements its own pretty-printing so that it can show register names instead of register offsets in PUT and GET instructions.

PyVEX is accessible through angr through the `Project.factory.block` interface. There are many different representations you could use to access syntactic properties of a block of code, but they all have in common the trait of analyzing a particular sequence of bytes. Through the `factory.block` constructor, you get a `Block` object that can be easily turned into several different representations. Try `.vex` for a PyVEX IRSB, or `.capstone` for a Capstone block.

Let's play with PyVEX:

```
>>> import angr

# load the program binary
>>> proj = angr.Project("/bin/true")

# translate the starting basic block
>>> irsb = proj.factory.block(proj.entry).vex
# and then pretty-print it
>>> irsb.pp()

# translate and pretty-print a basic block starting at an address
>>> irsb = proj.factory.block(0x401340).vex
>>> irsb.pp()

# this is the IR Expression of the jump target of the unconditional exit at the end of␣
↪the basic block
>>> print(irsb.next)

# this is the type of the unconditional exit (e.g., a call, ret, syscall, etc)
>>> print(irsb.jumpkind)

# you can also pretty-print it
>>> irsb.next.pp()

# iterate through each statement and print all the statements
>>> for stmt in irsb.statements:
...     stmt.pp()

# pretty-print the IR expression representing the data, and the *type* of that IR␣
↪expression written by every store statement
>>> import pyvex
>>> for stmt in irsb.statements:
...     if isinstance(stmt, pyvex.IRStmt.Store):
...         print("Data:",)
...         stmt.data.pp()
...         print("")
...         print("Type:",)
...         print(stmt.data.result_type)
```

(continues on next page)

(continued from previous page)

```
...         print("")

# pretty-print the condition and jump target of every conditional exit from the basic␣
↪block
>>> for stmt in irsb.statements:
...     if isinstance(stmt, pyvex.IRStmt.Exit):
...         print("Condition:",)
...         stmt.guard.pp()
...         print("")
...         print("Target:",)
...         stmt.dst.pp()
...         print("")

# these are the types of every temp in the IRSB
>>> print(irsb.tyenv.types)

# here is one way to get the type of temp 0
>>> print(irsb.tyenv.types[0])
```

### 5.6.1 Condition flags computation (for x86 and ARM)

One of the most common instruction side-effects on x86 and ARM CPUs is updating condition flags, such as the zero flag, the carry flag, or the overflow flag. Computer architects usually put the concatenation of these flags (yes, concatenation of the flags, since each condition flag is 1 bit wide) into a special register (i.e. `EFLAGS/RFLAGS` on x86, `APSR/CPSR` on ARM). This special register stores important information about the program state, and is critical for correct emulation of the CPU.

VEX uses 4 registers as its "Flag thunk descriptors" to record details of the latest flag-setting operation. VEX has a lazy strategy to compute the flags: when an operation that would update the flags happens, instead of computing the flags, VEX stores a code representing this operation to the `cc_op` pseudo-register, and the arguments to the operation in `cc_dep1` and `cc_dep2`. Then, whenever VEX needs to get the actual flag values, it can figure out what the one bit corresponding to the flag in question actually is, based on its flag thunk descriptors. This is an optimization in the flags computation, as VEX can now just directly perform the relevant operation in the IR without bothering to compute and update the flags' value.

Amongst different operations that can be placed in `cc_op`, there is a special value 0 which corresponds to `OP_COPY` operation. This operation is supposed to copy the value in `cc_dep1` to the flags. It simply means that `cc_dep1` contains the flags' value. angr uses this fact to let us efficiently retrieve the flags' value: whenever we ask for the actual flags, angr computes their value, then dumps them back into `cc_dep1` and sets `cc_op = OP_COPY` in order to cache the computation. We can also use this operation to allow the user to write to the flags: we just set `cc_op = OP_COPY` to say that a new value being set to the flags, then set `cc_dep1` to that new value.

## 5.7 Working with Data and Conventions

Frequently, you'll want to access structured data from the program you're analyzing. angr has several features to make this less of a headache.

### 5.7.1 Working with types

angr has a system for representing types. These SimTypes are found in `angr.types` - an instance of any of these classes represents a type. Many of the types are incomplete unless they are supplemented with a SimState - their size depends on the architecture you're running under. You may do this with `ty.with_arch(arch)`, which returns a copy of itself, with the architecture specified.

angr also has a light wrapper around `pycparser`, which is a C parser. This helps with getting instances of type objects:

```
>>> import angr, monkeyhex

# note that SimType objects have their __repr__ defined to return their c type name,
# so this function actually returned a SimType instance.
>>> angr.types.parse_type('int')
int

>>> angr.types.parse_type('char **')
char**

>>> angr.types.parse_type('struct aa {int x; long y;}')
struct aa

>>> angr.types.parse_type('struct aa {int x; long y;}').fields
OrderedDict([('x', int), ('y', long)])
```

Additionally, you may parse C definitions and have them returned to you in a dict, either of variable/function declarations or of newly defined types:

```
>>> angr.types.parse_defns("int x; typedef struct llist { char* str; struct llist *next;␣
↪} list_node; list_node *y;")
{'x': int, 'y': struct llist*}

>>> defs = angr.types.parse_types("int x; typedef struct llist { char* str; struct llist␣
↪*next; } list_node; list_node *y;")
>>> defs
{'struct llist': struct llist, 'list_node': struct llist}

# if you want to get both of these dicts at once, use parse_file, which returns both in␣
↪a tuple.
>>> angr.types.parse_file("int x; typedef struct llist { char* str; struct llist *next; }
↪ list_node; list_node *y;")
({'x': int, 'y': struct llist*},
 {'struct llist': struct llist, 'list_node': struct llist})

>>> defs['list_node'].fields
OrderedDict([('str', char*), ('next', struct llist*)])

>>> defs['list_node'].fields['next'].pts_to.fields
OrderedDict([('str', char*), ('next', struct llist*)])

# If you want to get a function type and you don't want to construct it manually,
# you can use parse_type
>>> angr.types.parse_type("int (int y, double z)")
(int, double) -> int
```

And finally, you can register struct definitions for future use:

```
>>> angr.types.register_types(angr.types.parse_type('struct abcd { int x; int y; }'))
>>> angr.types.register_types(angr.types.parse_types('typedef long time_t;'))
>>> angr.types.parse_defns('struct abcd a; time_t b;')
{'a': struct abcd, 'b': long}
```

These type objects aren't all that useful on their own, but they can be passed to other parts of angr to specify data types.

### 5.7.2 Accessing typed data from memory

Now that you know how angr's type system works, you can unlock the full power of the `state.mem` interface! Any type that's registered with the types module can be used to extract data from memory.

```
>>> p = angr.Project('examples/fauxware/fauxware')
>>> s = p.factory.entry_state()
>>> s.mem[0x601048]
<<untyped> <unresolvable> at 0x601048>

>>> s.mem[0x601048].long
<long (64 bits) <BV64 0x4008d0> at 0x601048>

>>> s.mem[0x601048].long.resolved
<BV64 0x4008d0>

>>> s.mem[0x601048].long.concrete
0x4008d0

>>> s.mem[0x601048].struct.abcd
<struct abcd {
  .x = <BV32 0x4008d0>,
  .y = <BV32 0x0>
} at 0x601048>

>>> s.mem[0x601048].struct.abcd.x
<int (32 bits) <BV32 0x4008d0> at 0x601048>

>>> s.mem[0x601048].struct.abcd.y
<int (32 bits) <BV32 0x0> at 0x60104c>

>>> s.mem[0x601048].deref
<<untyped> <unresolvable> at 0x4008d0>

>>> s.mem[0x601048].deref.string
<string_t <BV64 0x534f534e45414b59> at 0x4008d0>

>>> s.mem[0x601048].deref.string.resolved
<BV64 0x534f534e45414b59>

>>> s.mem[0x601048].deref.string.concrete
b'SOSNEAKY'
```

The interface works like this:

- You first use [array index notation] to specify the address you'd like to load from
- If at that address is a pointer, you may access the `deref` property to return a SimMemView at the address present in memory.
- You then specify a type for the data by simply accessing a property of that name. For a list of supported types, look at `state.mem.types`.
- You can then *refine* the type. Any type may support any refinement it likes. Right now the only refinements

supported are that you may access any member of a struct by its member name, and you may index into a string or array to access that element.

- If the address you specified initially points to an array of that type, you can say `.array(n)` to view the data as an array of n elements.
- Finally, extract the structured data with `.resolved` or `.concrete`. `.resolved` will return bitvector values, while `.concrete` will return integer, string, array, etc values, whatever best represents the data.
- Alternately, you may store a value to memory, by assigning to the chain of properties that you've constructed. Note that because of the way Python works, `x = s.mem[...].prop; x = val` will NOT work, you must say `s.mem[...].prop = val`.

If you define a struct using `register_types(parse_type(struct_expr))`, you can access it here as a type:

```
>>> s.mem[p.entry].struct.abcd
<struct abcd {
  .x = <BV32 0x8949ed31>,
  .y = <BV32 0x89485ed1>
} at 0x400580>
```

### 5.7.3 Working with Calling Conventions

A calling convention is the specific means by which code passes arguments and return values through function calls. angr's abstraction of calling conventions is called SimCC. You can construct new SimCC instances through the angr object factory, with `p.factory.cc(...)`. This will give a calling convention which is guessed based your guest architecture and OS. If angr guesses wrong, you can explicitly pick one of the calling conventions in the `angr.calling_conventions` module.

If you have a very wacky calling convention, you can use `angr.calling_conventions.SimCCUsercall`. This will ask you to specify locations for the arguments and the return value. To do this, use instances of the `SimRegArg` or `SimStackArg` classes. You can find them in the factory - `p.factory.cc.Sim*Arg`.

Once you have a SimCC object, you can use it along with a SimState object and a function prototype (a SimTypeFunction) to extract or store function arguments more cleanly. Take a look at the `angr.calling_conventions.SimCC>` for details. Alternately, you can pass it to an interface that can use it to modify its own behavior, like `p.factory.call_state`, or...

### 5.7.4 Callables

Callables are a Foreign Functions Interface (FFI) for symbolic execution. Basic callable usage is to create one with `myfunc = p.factory.callable(addr)`, and then call it! `result = myfunc(args, ...)` When you call the callable, angr will set up a `call_state` at the given address, dump the given arguments into memory, and run a `path_group` based on this state until all the paths have exited from the function. Then, it merges all the result states together, pulls the return value out of that state, and returns it.

All the interaction with the state happens with the aid of a `SimCC` and a `SimTypeFunction`, to tell where to put the arguments and where to get the return value. It will try to use a sane default for the architecture, but if you'd like to customize it, you can pass a `SimCC` object in the `cc` keyword argument when constructing the callable. The `SimTypeFunction` is required - you must pass the `prototype` parameter. If you pass a string to this parameter it will be parsed as a function declaration.

You can pass symbolic data as function arguments, and everything will work fine. You can even pass more complicated data, like strings, lists, and structures as native Python data (use tuples for structures), and it'll be serialized as cleanly as possible into the state. If you'd like to specify a pointer to a certain value, you can wrap it in a `PointerWrapper` object, available as `p.factory.callable.PointerWrapper`. The exact semantics of how pointer-wrapping work are a little confusing, but they can be boiled down to "unless you specify it with a PointerWrapper or a specific SimArrayType, nothing will be wrapped in a pointer automatically unless it gets to the end and it hasn't yet been wrapped in a pointer

yet and the original type is a string, array, or tuple." The relevant code is actually in SimCC - it's the `setup_callsite` function.

If you don't care for the actual return value of the call, you can say `func.perform_call(arg, ...)`, and then the properties `func.result_state` and `func.result_path_group` will be populated. They will actually be populated even if you call the callable normally, but you probably care about them more in this case!

## 5.8 Solver Engine

angr's solver engine is called Claripy. Claripy exposes the following design:

- Claripy ASTs (the subclasses of angr.claripy.ast.Base) provide a unified way to interact with concrete and symbolic expressions
- `Frontend`s provide different paradigms for evaluating these expressions. For example, the `FullFrontend` solves expressions using something like an SMT solver backend, while `LightFrontend` handles them by using an abstract (and approximating) data domain backend.
- Each `Frontend` needs to, at some point, do actual operation and evaluations on an AST. ASTs don't support this on their own. Instead, `Backend`s translate ASTs into backend objects (i.e., Python primitives for `BackendConcrete`, Z3 expressions for `BackendZ3`, strided intervals for `BackendVSA`, etc) and handle any appropriate state-tracking objects (such as tracking the solver state in the case of `BackendZ3`). Roughly speaking, frontends take ASTs as inputs and use backends to `backend.convert()` those ASTs into backend objects that can be evaluated and otherwise reasoned about.
- `FrontendMixin`s customize the operation of `Frontend`s. For example, `ModelCacheMixin` caches solutions from an SMT solver.
- The combination of a Frontend, a number of FrontendMixins, and a number of Backends comprise a claripy `Solver`.

Internally, Claripy seamlessly mediates the co-operation of multiple disparate backends – concrete bitvectors, VSA constructs, and SAT solvers. It is pretty badass.

Most users of angr will not need to interact directly with Claripy (except for, maybe, claripy AST objects, which represent symbolic expressions) – angr handles most interactions with Claripy internally. However, for dealing with expressions, an understanding of Claripy might be useful.

### 5.8.1 Claripy ASTs

Claripy ASTs abstract away the differences between mathematical constructs that Claripy supports. They define a tree of operations (i.e., `(a + b) / c`) on any type of underlying data. Claripy handles the application of these operations on the underlying objects themselves by dispatching requests to the backends.

Currently, Claripy supports the following types of ASTs:

| Nam | Description | Supported By (Claripy Backends) | Example Code |
|---|---|---|---|
| BV | This is a bitvector, whether symbolic (with a name) or concrete (with a value). It has a size (in bits). | BackendConcrete, BackendVSA, BackendZ3 | Create a 32-bit symbolic bitvector "x": *claripy.BVS('x', 32)* Create a 32-bit bitvector with the value *0xc001b3475*: *claripy.BVV(0xc001b3a75, 32)`</li><li>Create a 32-bit "strided interval" (see VSA documentation) that can be any divisible-by-10 number between 1000 and 2000: `claripy.SI(name='x', bits=32, lower_bound=1000, upper_bound=2000, stride=10)`</li></ul>* |
| FP | This is a floating-point number, whether symbolic (with a name) or concrete (with a value). | BackendConcrete, BackendZ3 | Create a `claripy.fp.FSORT_DOUBLE` symbolic floating point "b": `claripy.FPS('b', claripy.fp.FSORT_DOUBLE)`. Create a `claripy.fp.FSORT_FLOAT` floating point with value `3.2`: `claripy.FPV(3.2, claripy.fp.FSORT_FLOAT)`. |
| Bool | This is a boolean operation (True or False). | BackendConcrete, BackendVSA, BackendZ3 | `claripy.BoolV(True)`, or `claripy.true` or `claripy.false`, or by comparing two ASTs (i.e., `claripy.BVS('x', 32) < claripy.BVS('y', 32)` |

All of the above creation code returns claripy.AST objects, on which operations can then be carried out.

ASTs provide several useful operations.

```
>>> from angr import claripy

>>> bv = claripy.BVV(0x41424344, 32)

# Size - you can get the size of an AST with .size()
>>> assert bv.size() == 32

# Reversing - .reversed is the reversed version of the BVV
>>> assert bv.reversed is claripy.BVV(0x44434241, 32)
>>> assert bv.reversed.reversed is bv

# Depth - you can get the depth of the AST
>>> print(bv.depth)
>>> assert bv.depth == 1
>>> x = claripy.BVS('x', 32)
>>> assert (x+bv).depth == 2
>>> assert ((x+bv)/10).depth == 3
```

Applying a condition (==, !=, etc) on ASTs will return an AST that represents the condition being carried out. For example:

```
>>> r = bv == x
>>> assert isinstance(r, claripy.ast.Bool)

>>> p = bv == bv
>>> assert isinstance(p, claripy.ast.Bool)
>>> assert p.is_true()
```

You can combine these conditions in different ways.

```
>>> q = claripy.And(claripy.Or(bv == x, bv * 2 == x, bv * 3 == x), x == 0)
>>> assert isinstance(p, claripy.ast.Bool)
```

The usefulness of this will become apparent when we discuss Claripy solvers.

In general, Claripy supports all of the normal Python operations (+, -, |, ==, etc), and provides additional ones via the Claripy instance object. Here's a list of available operations from the latter.

| Name | Description | Example |
|---|---|---|
| LShR | Logically shifts a bit expression (BVV, BV, SI) to the right. | `claripy.LShR(x, 10)` |
| SignExt | Sign-extends a bit expression. | `claripy.SignExt(32, x)` or `x.sign_extend(32)` |
| ZeroExt | Zero-extends a bit expression. | `claripy.ZeroExt(32, x)` or `x.zero_extend(32)` |
| Extract | Extracts the given bits (zero-indexed from the *right*, inclusive) from a bit expression. | Extract the rightmost byte of x: `claripy.Extract(7, 0, x)` or `x[7:0]` |
| Concat | Concatenates several bit expressions together into a new bit expression. | `claripy.Concat(x, y, z)` |
| RotateLeft | Rotates a bit expression left. | `claripy.RotateLeft(x, 8)` |
| RotateRight | Rotates a bit expression right. | `claripy.RotateRight(x, 8)` |
| Reverse | Endian-reverses a bit expression. | `claripy.Reverse(x)` or `x.reversed` |
| And | Logical And (on boolean expressions) | `claripy.And(x == y, x > 0)` |
| Or | Logical Or (on boolean expressions) | `claripy.Or(x == y, y < 10)` |
| Not | Logical Not (on a boolean expression) | `claripy.Not(x == y)` is the same as `x != y` |
| If | An If-then-else | Choose the maximum of two expressions: `claripy.If(x > y, x, y)` |
| ULE | Unsigned less than or equal to. | Check if x is less than or equal to y: `claripy.ULE(x, y)` |
| ULT | Unsigned less than. | Check if x is less than y: `claripy.ULT(x, y)` |
| UGE | Unsigned greater than or equal to. | Check if x is greater than or equal to y: `claripy.UGE(x, y)` |
| UGT | Unsigned greater than. | Check if x is greater than y: `claripy.UGT(x, y)` |
| SLE | Signed less than or equal to. | Check if x is less than or equal to y: `claripy.SLE(x, y)` |
| SLT | Signed less than. | Check if x is less than y: `claripy.SLT(x, y)` |
| SGE | Signed greater than or equal to. | Check if x is greater than or equal to y: `claripy.SGE(x, y)` |
| SGT | Signed greater than. | Check if x is greater than y: `claripy.SGT(x, y)` |

> **Note**
>
> The default Python >, <, >=, and <= are unsigned in Claripy. This is different than their behavior in Z3, because it seems more natural in binary analysis.

### 5.8.2 Solvers

The main point of interaction with Claripy are the Claripy Solvers. Solvers expose an API to interpret ASTs in different ways and return usable values. There are several different solvers.

| Name | Description |
|---|---|
| Solver | This is analogous to a `z3.Solver()`. It is a solver that tracks constraints on symbolic variables and uses a constraint solver (currently, Z3) to evaluate symbolic expressions. |
| SolverVSA | This solver uses VSA to reason about values. It is an *approximating* solver, but produces values without performing actual constraint solves. |
| SolverReplacement | This solver acts as a pass-through to a child solver, allowing the replacement of expressions on-the-fly. It is used as a helper by other solvers and can be used directly to implement exotic analyses. |
| SolverHybrid | This solver combines the SolverReplacement and the Solver (VSA and Z3) to allow for *approximating* values. You can specify whether or not you want an exact result from your evaluations, and this solver does the rest. |
| SolverComposite | This solver implements optimizations that solve smaller sets of constraints to speed up constraint solving. |

Some examples of solver usage:

```
# create the solver and an expression
>>> s = claripy.Solver()
>>> x = claripy.BVS('x', 8)

# now let's add a constraint on x
>>> s.add(claripy.ULT(x, 5))

>>> assert sorted(s.eval(x, 10)) == [0, 1, 2, 3, 4]
>>> assert s.max(x) == 4
>>> assert s.min(x) == 0

# we can also get the values of complex expressions
>>> y = claripy.BVV(65, 8)
>>> z = claripy.If(x == 1, x, y)
>>> assert sorted(s.eval(z, 10)) == [1, 65]

# and, of course, we can add constraints on complex expressions
>>> s.add(z % 5 != 0)
>>> assert s.eval(z, 10) == (1,)
>>> assert s.eval(x, 10) == (1,) # interestingly enough, since z can't be y, x can only␣
↪be 1!
```

Custom solvers can be built by combining a Claripy Frontend (the class that handles the actual interaction with SMT solver or the underlying data domain) and some combination of frontend mixins (that handle things like caching, filtering out duplicate constraints, doing opportunistic simplification, and so on).

### 5.8.3 Claripy Backends

Backends are Claripy's workhorses. Claripy exposes ASTs to the world, but when actual computation has to be done, it pushes those ASTs into objects that can be handled by the backends themselves. This provides a unified interface to the outside world while allowing Claripy to support different types of computation. For example, BackendConcrete provides computation support for concrete bitvectors and booleans, BackendVSA introduces VSA constructs such as StridedIntervals (and details what happens when operations are performed on them, and BackendZ3 provides support for symbolic variables and constraint solving.

There are a set of functions that a backend is expected to implement. For all of these functions, the "public" version is expected to be able to deal with claripy's AST objects, while the "private" version should only deal with objects specific to the backend itself. This is distinguished with Python idioms: a public function will be named func() while a private function will be _func(). All functions should return objects that are usable by the backend in its private methods. If this can't be done (i.e., some functionality is being attempted that the backend can't handle), the backend should raise a BackendError. In this case, Claripy will move on to the next backend in its list.

All backends must implement a `convert()` function. This function receives a claripy AST and should return an object that the backend can handle in its private methods. Backends should also implement a `convert()` method, which will receive anything that is *not* a claripy AST object (i.e., an integer or an object from a different backend). If `convert()` or `convert()` receives something that the backend can't translate to a format that is usable internally, the backend should raise BackendError, and thus won't be used for that object. All backends must also implement any functions of the base `Backend` abstract class that currently raise `NotImplementedError()`.

Claripy's contract with its backends is as follows: backends should be able to handle, in their private functions, any object that they return from their private *or* public functions. Claripy will never pass an object to any backend private function that did not originate as a return value from a private or public function of that backend. One exception to this is `convert()` and `convert()`, as Claripy can try to stuff anything it feels like into _convert() to see if the backend can handle that type of object.

#### Backend Objects

To perform actual, useful computation on ASTs, Claripy uses backend objects. A `BackendObject` is a result of the operation represented by the AST. Claripy expects these objects to be returned from their respective backends, and will pass such objects into that backend's other functions.

## 5.9 Symbolic memory addressing

angr supports *symbolic memory addressing*, meaning that offsets into memory may be symbolic. Our implementation of this is inspired by "Mayhem". Specifically, this means that angr concretizes symbolic addresses when they are used as the target of a write. This causes some surprises, as users tend to expect symbolic writes to be treated purely symbolically, or "as symbolically" as we treat symbolic reads, but that is not the default behavior. However, like most things in angr, this is configurable.

The address resolution behavior is governed by *concretization strategies*, which are subclasses of `angr.concretization_strategies.SimConcretizationStrategy`. Concretization strategies for reads are set in `state.memory.read_strategies` and for writes in `state.memory.write_strategies`. These strategies are called, in order, until one of them is able to resolve addresses for the symbolic index. By setting your own concretization strategies (or through the use of SimInspect `address_concretization` breakpoints, described above), you can change the way angr resolves symbolic addresses.

For example, angr's default concretization strategies for writes are:

1. A conditional concretization strategy that allows symbolic writes (with a maximum range of 128 possible solutions) for any indices that are annotated with `angr.plugins.symbolic_memory.MultiwriteAnnotation`.
2. A concretization strategy that simply selects the maximum possible solution of the symbolic index.

To enable symbolic writes for all indices, you can either add the `SYMBOLIC_WRITE_ADDRESSES` state option at state creation time or manually insert a `angr.concretization_strategies.SimConcretizationStrategyRange` object into `state.memory.write_strategies`. The strategy object takes a single argument, which is the maximum range of possible solutions that it allows before giving up and moving on to the next (presumably non-symbolic) strategy.

### 5.9.1 Writing concretization strategies

**Todo**

Write this section

## 5.10 Java Support

`angr` also supports symbolically executing Java code and Android apps! This also includes Android apps using a combination of compiled Java and native (C/C++) code.

**Warning**

Java support is experimental! Contribution from the community is highly encouraged! Pull requests are very welcomed!

We implemented Java support by lifting the compiled Java code, both Java and DEX bytecode, leveraging our Soot Python wrapper: pysoot. `pysoot` extracts a fully serializable interface from Android apps and Java code (unfortunately, as of now, it only works on Linux). For every class of the generated IR (for instance, `SootMethod`), you can nicely print its instructions (in a format similar to `Soot shimple`) using `print()` or `str()`.

**Note**

Windows and macOS support is available on a branch. It should pass all tests and generally work well, but due to issues integrating JPype into CI infrastructure, it has not yet been merged.

We then leverage the generated IR in a new angr engine able to run code in Soot IR: angr/engines/soot/engine.py. This engine is also able to automatically switch to executing native code if the Java code calls any native method using the JNI interface.

Together with the symbolic execution, we also implemented some basic static analysis, specifically a basic CFG reconstruction analysis. Moreover, we added support for string constraint solving, modifying claripy and using the CVC4 solver.

### 5.10.1 How to install

Java support requires the `pysoot` package, which is not included in the default angr installation. You can install it from GitHub using pip:

```
git clone https://github.com/angr/pysoot.git
cd pysoot
pip install -e .
```

Alternatively, pysoot can be installed with the setup script in angr-dev:

```
./setup.sh pysoot
```

#### Analyzing Android apps.

Analyzing Android apps (`.APK` files, containing Java code compiled to the `DEX` format) requires the Android SDK. Typically, it is installed in `<HOME>/Android/SDK/platforms/platform-XX/android.jar`, where `XX` is the Android SDK version used by the app you want to analyze (you may want to install all the platforms required by the Android apps you want to analyze).

### 5.10.2 Examples

There are multiple examples available:

- Easy Java crackmes: java_crackme1, java_simple3, java_simple4
- A more complex example (solving a CTF challenge): ictf2017_javaisnotfun, blogpost
- Symbolically executing an Android app (using a mix of Java and native code): java_androidnative1
- Many other low-level tests: test_java

## 5.11 Debug variable resolution

angr now support resolve source level variable (debug variable) in binary with debug information. This article will introduce you how to use it.

### 5.11.1 Setting up

To use it you need binary that is compiled with dwarf debugging information (ex: `gcc -g`) and load in angr with the option `load_debug_info`. After that you need to run `project.kb.dvars.load_from_dwarf()` to set up the feature and we're set.

Overall it looks like this:

```
# compile your binary with debug information
gcc -g -o debug_var debug_var.c
```

```
>>> import angr
>>> project = angr.Project('./examples/debug_var/simple_var', load_debug_info = True)
>>> project.kb.dvars.load_from_dwarf()
```

### 5.11.2 Core feature

With things now set up you can view the value in the angr memory view of the debug variable within a state with: `state.dvars['variable_name'].mem` or the value that it point to if it is a pointer with: `state.dvars['pointer_name'].deref.mem`. Here are some example:

Given the source code in `examples/debug_var/simple_var.c`

```
#include<stdio.h>

int global_var = 100;
int main(void){
   int a = 10;
   int* b = &a;
```

(continues on next page)

(continued from previous page)

```
   printf("%d\n", *b);
   {
      int a = 24;
      *b = *b + a;
      int c[] = {5, 6, 7, 8};
      printf("%d\n", a);
   }
   return 0;
}
```

```
# Get a state before executing printf(%d\n", *b) (line 7)
# the addr to line 7 is 0x401193 you can search for it with
>>> project.loader.main_object.addr_to_line
{...}
>>> addr = 0x401193
# Create an simulation manager and run to that addr
>>> simgr = project.factory.simgr()
>>> simgr.explore(find = addr)
<SimulationManager with 1 found>
>>> state = simgr.found[0]
# Resolve 'a' in state
>>> state.dvars['a'].mem
<int (32 bits) <BV32 0xa> at 0x7fffffffffeff30>
# Dereference pointer b
>>> state.dvars['b'].deref.mem
<int (32 bits) <BV32 0xa> at 0x7fffffffffeff30>
# It works as expected when resolving the value of b gives the address of a
>>> state.dvars['b'].mem
<reg64_t <BV64 0x7fffffffffeff30> at 0x7fffffffffeff38>
```

Side-note: For string type you can use `.string` instead of `.mem` to resolve it. For struct type you can resolve its member by `.member("member_name").mem`. For array type you can use `.array(index).mem` to access the element in array.

## 5.12 Variable visibility

If you have many variable with the same name but in different scope, calling `state.dvars['var_name']` would resolve the variable with the nearest scope.

Example:

```
# Find the addr before executing printf("%d\n", a) (line 12)
# with the same method to find addr
>>> addr = 0x4011e0
# Explore until find state
>>> simgr.move(from_stash='found', to_stash='active')
<SimulationManager with 1 active>
>>> simgr.explore(find = addr)
<SimulationManager with 1 found>
>>> state = simgr.found[0]
# Resolve 'a' in state before execute line 10
>>> state.dvars['a'].mem
<int (32 bits) <BV32 0x18> at 0x7fffffffffeff34>
```

Congratulation, you've now know how to resolve debug variable using angr, for more info check out the api-doc.

CHAPTER

SIX

# EXTENDING ANGR

## 6.1 Hooks and SimProcedures

Hooks in angr are very powerful! You can use them to modify a program's behavior in any way you could imagine. However, the exact way you might want to program a specific hook may be non-obvious. This chapter should serve as a guide when programming SimProcedures.

### 6.1.1 Quick Start

Here's an example that will remove all bugs from any program:

```
>>> from angr import Project, SimProcedure
>>> project = Project('examples/fauxware/fauxware')

>>> class BugFree(SimProcedure):
...     def run(self, argc, argv):
...         print('Program running with argc=%s and argv=%s' % (argc, argv))
...         return 0

# this assumes we have symbols for the binary
>>> project.hook_symbol('main', BugFree())

# Run a quick execution!
>>> simgr = project.factory.simulation_manager()
>>> simgr.run()  # step until no more active states
Program running with argc=<SAO <BV64 0x0>> and argv=<SAO <BV64 0x7fffffffffeffa0>>
<SimulationManager with 1 deadended>
```

Now, whenever program execution reaches the main function, instead of executing the actual main function, it will execute this procedure! It just prints out a message, and returns.

Now, let's talk about what happens on the edge of this function! When entering the function, where do the values that go into the arguments come from? You can define your `run()` function with however many arguments you like, and the SimProcedure runtime will automatically extract from the program state those arguments for you, via a *calling convention*, and call your run function with them. Similarly, when you return a value from the run function, it is placed into the state (again, according to the calling convention), and the actual control-flow action of returning from a function is performed, which depending on the architecture may involve jumping to the link register or jumping to the result of a stack pop.

It should be clear at this point that the SimProcedure we just wrote is meant to totally replace whatever function it is hooked over top of. In fact, the original use case for SimProcedures was replacing library functions. More on that later.

### 6.1.2 Implementation Context

On a `Project` class, the dict `project._sim_procedures` is a mapping from address to `SimProcedure` instances. When the *execution pipeline* reaches an address that is present in that dict, that is, an address that is hooked, it will execute `project._sim_procedures[address].execute(state)`. This will consult the calling convention to extract the arguments, make a copy of itself in order to preserve thread safety, and run the `run()` method. It is important to produce a new instance of the SimProcedure for each time it is run, since the process of running a SimProcedure necessarily involves mutating state on the SimProcedure instance, so we need separate ones for each step, lest we run into race conditions in multithreaded environments.

#### kwargs

This hierarchy implies that you might want to reuse a single SimProcedure in multiple hooks. What if you want to hook the same SimProcedure in several places, but tweaked slightly each time? angr's support for this is that any additional keyword arguments you pass to the constructor of your SimProcedure will end up getting passed as keyword args to your SimProcedure's `run()` method. Pretty cool!

### 6.1.3 Data Types

If you were paying attention to the example earlier, you noticed that when we printed out the arguments to the `run()` function, they came out as a weird `<SAO <BV64 0xSTUFF>>` class. This is a `SimActionObject`. Basically, you don't need to worry about it too much, it's just a thin wrapper over a normal bitvector. It does a bit of tracking of what exactly you do with it inside the SimProcedure—this is helpful for static analysis.

You may also have noticed that we directly returned the Python int `0` from the procedure. This will automatically be promoted to a word-sized bitvector! You can return a native number, a bitvector, or a SimActionObject.

When you want to write a procedure that deals with floating point numbers, you will need to specify the calling convention manually. It's not too hard, just provide a cc to the hook: `` `cc = project.factory.cc_from_arg_kinds((True, True), ret_fp=True) `` and `project.hook(address, ProcedureClass(cc=mycc))` This method for passing in a calling convention works for all calling conventions, so if angr's autodetected one isn't right, you can fix that.

### 6.1.4 Control Flow

How can you exit a SimProcedure? We've already gone over the simplest way to do this, returning a value from `run()`. This is actually shorthand for calling `self.ret(value)`. `self.ret()` is the function which knows how to perform the specific action of returning from a function.

SimProcedures can use lots of different functions like this!

- `ret(expr)`: Return from a function
- `jump(addr)`: Jump to an address in the binary
- `exit(code)`: Terminate the program
- `call(addr, args, continue_at)`: Call a function in the binary
- `inline_call(procedure, *args)`: Call another SimProcedure in-line and return the results

That second-last one deserves some looking-at. We'll get there after a quick detour...

#### Conditional Exits

What if we want to add a conditional branch out of a SimProcedure? In order to do that, you'll need to work directly with the SimSuccessors object for the current execution step.

The interface for this is `self.successors.add_successor(state, addr, guard, jumpkind)`. All of these parameters should have an obvious meaning if you've followed along so far. Keep in mind that the state you pass in will NOT be copied and WILL be mutated, so be sure to make a copy beforehand if there will be more work to do!

### SimProcedure Continuations

How can we call a function in the binary and have execution resume within our SimProcedure? There is a whole bunch of infrastructure called the "SimProcedure Continuation" that will let you do this. When you use `self.call(addr, args, continue_at)`, `addr` is expected to be the address you'd like to call, `args` is the tuple of arguments you'd like to call it with, and `continue_at` is the name of another method in your SimProcedure class that you'd like execution to continue at when it returns. This method must have the same signature as the `run()` method. Furthermore, you can pass the keyword argument `cc` as the calling convention that ought to be used to communicate with the callee.

When you do this, you finish your current step, and execution will start again at the next step at the function you've specified. When that function returns, it has to return to some concrete address! That address is specified by the SimProcedure runtime: an address is allocated in angr's externs segment to be used as the return site for returning to the given method call. It is then hooked with a copy of the procedure instance tweaked to run the specified `continue_at` function instead of `run()`, with the same args and kwargs as the first time.

There are two pieces of metadata you need to attach to your SimProcedure class in order to use the continuation subsystem correctly:

- Set the class variable `IS_FUNCTION = True`
- Set the class variable `local_vars` to a tuple of strings, where each string is the name of an instance variable on your SimProcedure whose value you would like to persist to when you return. Local variables can be any type so long as you don't mutate their instances.

You may have guessed by now that there exists some sort of auxiliary storage in order to hold on to all this data. You would be right! The state plugin `state.callstack` has an entry called `.procedure_data` which is used by the SimProcedure runtime to store information local to the current call frame. angr tracks the stack pointer in order to make the current top of the `state.callstack` a meaningful local data store. It's stuff that ought to be stored in memory in a stack frame, but the data can't be serialized and/or memory allocation is hard.

As an example, let's look at the SimProcedure that angr uses internally to run all the shared library initializers for a `full_init_state` for a linux program:

```
class LinuxLoader(angr.SimProcedure):
    NO_RET = True
    IS_FUNCTION = True
    local_vars = ('initializers',)

    def run(self):
        self.initializers = self.project.loader.initializers
        self.run_initializer()

    def run_initializer(self):
        if len(self.initializers) == 0:
            self.project._simos.set_entry_register_values(self.state)
            self.jump(self.project.entry)
        else:
            addr = self.initializers[0]
            self.initializers = self.initializers[1:]
            self.call(addr, (self.state.posix.argc, self.state.posix.argv, self.state.
↪posix.environ), 'run_initializer')
```

This is a particularly clever usage of the SimProcedure continuations. First, notice that the current project is available for use on the procedure instance. This is some powerful stuff you can get yourself into; for safety you generally only want

to use the project as a read-only or append-only data structure. Here we're just getting the list of dynamic initializers from the loader. Then, for as long as the list isn't empty, we pop a single function pointer out of the list, being careful not to mutate the list, since the list object is shared across states, and then call it, returning to the `run_initializer` function again. When we run out of initializers, we set up the entry state and jump to the program entry point.

Very cool!

### 6.1.5 Global Variables

As a brief aside, you can store global variables in `state.globals`. This is a dictionary that just gets shallow-copied from state to successor state. Because it's only a shallow copy, its members are the same instances, so the same rules as local variables in SimProcedure continuations apply. You need to be careful not to mutate any item that is used as a global variable unless you know exactly what you're doing.

### 6.1.6 Helping out static analysis

We've already looked at the class variable `IS_FUNCTION`, which allows you to use the SimProcedure continuation. There are a few more class variables you can set, though these ones have no direct benefit to you - they merely mark attributes of your function so that static analysis knows what it's doing.

- `NO_RET`: Set this to true if control flow will never return from this function
- `ADDS_EXITS`: Set this to true if you do any control flow other than returning
- `IS_SYSCALL`: Self-explanatory

Furthermore, if you set `ADDS_EXITS = True`, you'll need to define the method `static_exits()`. This function takes a single parameter, a list of IRSBs that would be executed in the run-up to your function, and asks you to return a list of all the exits that you know would be produced by your function in that case. The return value is expected to be a list of tuples of (address (int), jumpkind (str)). This is meant to be a quick, best-effort analysis, and you shouldn't try to do anything crazy or intensive to get your answer.

### 6.1.7 User Hooks

The process of writing and using a SimProcedure makes a lot of assumptions that you want to hook over a whole function. What if you don't? There's an alternate interface for hooking, a *user hook*, that lets you streamline the process of hooking sections of code.

```
>>> @project.hook(0x1234, length=5)
... def set_rax(state):
...     state.regs.rax = 1
```

This is a lot simpler! The idea is to use a single function instead of an entire SimProcedure subclass. No extraction of arguments is performed, no complex control flow happens.

Control flow is controlled by the length argument. After the function finishes executing in this example, the next step will start at 5 bytes after the hooked address. If the length argument is omitted or set to zero, execution will resume executing the binary code at exactly the hooked address, without re-triggering the hook. The `Ijk_NoHook` jumpkind allows this to happen.

If you want more control over control flow coming out of a user hook, you can return a list of successor states. Each successor will be expected to have `state.regs.ip`, `state.scratch.guard`, and `state.scratch.jumpkind` set. The IP is the target instruction pointer, the guard is a symbolic boolean representing a constraint to add to the state related to it being taken as opposed to the others, and the jumpkind is a VEX enum string, like `Ijk_Boring`, representing the nature of the branch.

The general rule is, if you want your SimProcedure to either be able to extract function arguments or cause a program return, write a full SimProcedure class. Otherwise, use a user hook.

### 6.1.8 Hooking Symbols

As you should recall from the *section on loading a binary*, dynamically linked programs have a list of symbols that they must import from the libraries they have listed as dependencies, and angr will make sure, rain or shine, that every import symbol gets resolved by *some* address, whether it's a real implementation of the function or just a dummy address hooked with a do-nothing stub. As a result, you can just use the `Project.hook_symbol` API to hook the address referred to by a symbol!

This means that you can replace library functions with your own code. For instance, to replace `rand()` with a function that always returns a consistent sequence of values:

```
>>> class NotVeryRand(SimProcedure):
...     def run(self, return_values=None):
...         rand_idx = self.state.globals.get('rand_idx', 0) % len(return_values)
...         out = return_values[rand_idx]
...         self.state.globals['rand_idx'] = rand_idx + 1
...         return out

>>> project.hook_symbol('rand', NotVeryRand(return_values=[413, 612, 1025, 1111]))
```

Now, whenever the program tries to call `rand()`, it'll return the integers from the `return_values` array in a loop.

## 6.2 State Plugins

If you want to store some data on a state and have that information propagated from successor to successor, the easiest way to do this is with `state.globals`. However, this can become obnoxious with large amounts of interesting data, doesn't work at all for merging states, and isn't very object-oriented.

The solution to these problems is to write a *State Plugin* - an appendix to the state that holds data and implements an interface for dealing with the lifecycle of a state.

### 6.2.1 My First Plugin

Let's get started! All state plugins are implemented as subclasses of `SimStatePlugin`. Once you've read this document, you can use the API reference for this class *`angr.state_plugins.plugin.SimStatePlugin`* to quickly review the semantics of all the interfaces you should implement.

The most important method you need to implement is `copy`: it should be annotated with the `memo` staticmethod and take a dict called the "memo"—these'll be important later—and returns a copy of the plugin. Short of that, you can do whatever you want. Just make sure to call the superclass initializer!

```
>>> import angr
>>> from angr import claripy
>>> class MyFirstPlugin(angr.SimStatePlugin):
...     def __init__(self, foo):
...         super(MyFirstPlugin, self).__init__()
...         self.foo = foo
...
...     @angr.SimStatePlugin.memo
...     def copy(self, memo):
...         return MyFirstPlugin(self.foo)

>>> project = angr.load_shellcode(b'\x90', 'AMD64')
>>> state = angr.SimState(project=project)
>>> state.register_plugin('my_plugin', MyFirstPlugin('bar'))
```

(continues on next page)

(continued from previous page)

```
>>> assert state.my_plugin.foo == 'bar'

>>> state2 = state.copy()
>>> state.my_plugin.foo = 'baz'
>>> state3 = state.copy()
>>> assert state2.my_plugin.foo == 'bar'
>>> assert state3.my_plugin.foo == 'baz'
```

It works! Note that plugins automatically become available as attributes on the state. `state.get_plugin(name)` is also available as a more programmatic interface.

### 6.2.2 Where's the state?

State plugins have access to the state, right? So why isn't it part of the initializer? It turns out, there are a plethora of issues related to initialization order and dependency issues, so to simplify things as much as possible, the state is not part of the initializer but is rather set onto the state in a separate phase, by using the `set_state` method. You can override this state if you need to do things like propagate the state to subcomponents or extract architectural information.

```
>>> def set_state(self, state):
...     super(SimStatePlugin, self).set_state(state)
...     self.symbolic_word = claripy.BVS('my_variable', self.state.arch.bits)
```

Note the `self.state`! That's what the super `set_state` sets up.

However, there's no guarantee on what order the states will be set onto the plugins in, so if you need to interact with *other plugins* for initialization, you need to override the `init_state` method.

Once again, there's no guarantee on what order these will be called in, so the rule is to make sure you set yourself up good enough during `set_state` so that if someone else tries to interact with you, no type errors will happen. Here's an example of a good use of `init_state`, to map a memory region in the state. The use of an instance variable (presumably copied as part of `copy()`) ensures this only happens the first time the plugin is added to a state.

```
>>> def init_state(self):
...     if self.region is None:
...         self.region = self.state.memory.map_region(SOMEWHERE, 0x1000, 7)
```

#### Note: weak references

`self.state` is not the state itself, but rather a weak proxy to the state. You can still use this object as a normal state, but attempts to store it persistently will not work.

### 6.2.3 Merging

The other element besides copying in the state lifecycle is merging. As input you get the plugins to merge and a list of "merge conditions" - symbolic booleans that are the "guard conditions" describing when the values from each state should actually apply.

The important properties of the merge conditions are:

- They are mutually exclusive and span an entire domain - exactly one may be satisfied at once, and there will be additional constraints to ensure that at least one must be satisfied.
- `len(merge_conditions)` == len(others) + 1, since `self` counts too.
- `zip(merge_conditions, [self] + others)` will correctly pair merge conditions with plugins.

During the merge function, you should *mutate* `self` to become the merged version of itself and all the others, with respect to the merge conditions. This involves using the if-then-else structure that claripy provides. Here is an example of constructing this merged structure by merging a bitvector instance variable called `myvar`, producing a binary tree of if-then-else expressions searching for the correct condition:

```
for other_plugin, condition in zip(others, merge_conditions[1:]): # chop off self's␣
↪condition
    self.myvar = claripy.If(condition, other_plugin.myvar, self.myvar)
```

This is such a common construction that we provide a utility to perform it automatically: `claripy.ite_cases`. The following code snippet is identical to the previous one:

```
self.myvar = claripy.ite_cases(zip(merge_conditions[1:], [o.myvar for o in others]),␣
↪self.myvar)
```

Keep in mind that like the rest of the top-level claripy functions, `ite_cases` and `If` are also available from `state.solver`, and these versions will perform SimActionObject unwrapping if applicable.

#### Common Ancestor

The full prototype of the `merge` interface is `def merge(self, others, merge_conditions, common_ancestor=None)`. `others` and `merge_conditions` have been discussed in depth already.

The common ancestor is the instance of the plugin from the most recent common ancestor of the states being merged. It may not be available for all merges, in which case it will be None. There are no rules for how exactly you should use this to improve the quality of your merges, but you may find it useful in more complex setups.

### 6.2.4 Serialization

In order to support serialization of states which contain your plugin, you should implement the `__getstate__`/`__setstate__` magic method pair. Keep in mind the following guidelines:

- Your serialization result should *not* include the state.
- After deserialization, `set_state()` will be called again.

This means that plugins are "detached" from the state and serialized in an isolated environment, and then reattached to the state on deserialization.

### 6.2.5 Plugins all the way down

You may have components within your state plugins which are large and complicated and start breaking object-orientation in order to make copy/merge work well with the state lifecycle. You're in luck! Things can be state plugins even if they aren't directly attached to a state. A great example of this is `SimFile`, which is a state plugin but is stored in the filesystem plugin, and is never used with `SimState.register_plugin`. When you're doing this, there are a handful of rules to remember which will keep your plugins safe and happy:

- Annotate your copy function with `@SimStatePlugin.memo`.
- In order to prevent *divergence* while copying multiple references to the same plugin, make sure you're passing the memo (the argument to copy) to the `.copy` of any subplugins. This with the previous point will preserve object identity.
- In order to prevent *duplicate merging* while merging multiple references to the same plugin, there should be a concept of the "owner" of each instance, and only the owner should run the merge routine.
- While passing arguments down into sub-plugins `merge()` routines, make sure you unwrap `others` and `common_ancestor` into the appropriate types. For example, if `PluginA` contains a `PluginB`, the former should do the following:

```
>>> def merge(self, others, merge_conditions, common_ancestor=None):
...     # ... merge self
...     self.plugin_b.merge([o.plugin_b for o in others], merge_conditions,
...         common_ancestor=None if common_ancestor is None else common_ancestor.plugin_
↪b)
```

### 6.2.6 Setting Defaults

To make it so that a plugin will automatically become available on a state when requested, without having to register it with the state first, you can register it as a *default*. The following code example will make it so that whenever you access `state.my_plugin`, a new instance of `MyPlugin` will be instantiated and registered with the state.

```
MyPlugin.register_default('my_plugin')
```

## 6.3 Extending the Environment Model

One of the biggest issues you may encounter while using angr to analyze programs is an incomplete model of the environment, or the APIs, surrounding your program. This usually takes the form of syscalls or dynamic library calls, or in rare cases, loader artifacts. angr provides a convenient interface to do most of these things!

Everything discussed here involves writing SimProcedures, so *make sure you know how to do that!*.

Note that this page should be treated as a narrative document, not a reference document, so you should read it at least once start to end.

### 6.3.1 Setup

You *probably* want to have a development install of angr, i.e. set up with the script in the angr-dev repository. It is remarkably easy to add new API models by just implementing them in certain folders of the angr repository. This is also desirable because any work you do in this field will almost always be useful to other people, and this makes it extremely easy to submit a pull request.

However, if you want to do your development out-of-tree, you want to work against a production version of angr, or you want to make customized versions of already-implemented API functions, there are ways to incorporate your extensions programmatically. Both these techniques, in-tree and out-of-tree, will be documented at each step.

### 6.3.2 Dynamic library functions - import dependencies

This is the easiest case, and the case that SimProcedures were originally designed for.

First, you need to write a SimProcedure representing the function. Then you need to let angr know about it.

#### Case 1, in-tree development: SimLibraries and catalogues

angr has a magical folder in its repository, angr/procedures. Within it are all the SimProcedure implementations that come bundled with angr as well as information about what libraries implement what functions.

Each folder in the `procedures` directory corresponds to some sort of *standard*, or a body that specifies the interface part of an API and its semantics. We call each folder a *catalog* of procedures. For example, we have `libc` which contains the functions defined by the C standard library, and a separate folder `posix` which contains the functions defined by the posix standard. There is some magic which automatically scrapes these folders in the `procedures` directory and organizes them into the `angr.SIM_PROCEDURES` dict. For example, `angr/procedures/libc/printf.py` contains both `class printf` and `class __printf_chk`, so there exists both `angr.SIM_PROCEDURES['libc']['printf']` and `angr.SIM_PROCEDURES['libc']['__printf_chk']`.

The purpose of this categorization is to enable easy sharing of procedures among different libraries. For example. libc.so.6 contains all the C standard library functions, but so does msvcrt.dll! These relationships are represented with objects called `SimLibraries` which represent an actual shared library file, its functions, and their metadata. Take a look at the API reference for *SimLibrary* along with the code for setting up glibc to learn how to use it.

SimLibraries are defined in a special folder in the procedures directory, `procedures/definitions`. Files in here should contain an *instance*, not a subclass, of `SimLibrary`. The same magic that scrapes up SimProcedures will also scrape up SimLibraries and put them in `angr.SIM_LIBRARIES`, keyed on each of their common names. For example, `angr/procedures/definitions/linux_loader.py` contains `lib = SimLibrary(); lib.set_library_names('ld.so', 'ld-linux.so', 'ld.so.2', 'ld-linux.so.2', 'ld-linux-x86_64.so.2')`, so you can access it via `angr.SIM_LIBRARIES['ld.so'][0]` or `angr.SIM_LIBRARIES['ld-linux.so'][0]` or any of the other names.

At load time, all the dynamic library dependencies are looked up in `SIM_LIBRARIES` and their procedures (or stubs!) are hooked into the project's address space to summarize any functions it can. The code for this process is found here.

**SO**, the bottom line is that you can just write your own SimProcedure and SimLibrary definitions, drop them into the directory structure, and they'll automatically be applied. If you're adding a procedure to an existing library, you can just drop it into the appropriate catalog and it'll be picked up by all the libraries using that catalog, since most libraries construct their list of function implementation by batch-adding entire catalogs.

#### Case 2, out-of-tree development, tight integration

If you'd like to implement your procedures outside the angr repository, you can do that. You effectively do this by just manually adding your procedures to the appropriate SimLibrary. Just call `angr.SIM_LIBRARIES[libname][0].add(name, proc_cls)` to do the registration.

Note that this will only work if you do this before the project is loaded with `angr.Project`. Note also that adding the procedure to `angr.SIM_PROCEDURES`, i.e. adding it directly to a catalog, will *not* work, since these catalogs are used to construct the SimLibraries only at import and are used by value, not by reference.

#### Case 3, out-of-tree development, loose integration

Finally, if you don't want to mess with SimLibraries at all, you can do things purely on the project level with *hook_symbol()*.

### 6.3.3 Syscalls

Unlike dynamic library methods, syscall procedures aren't incorporated into the project via hooks. Instead, whenever a syscall instruction is encountered, the basic block should end with a jumpkind of `Ijk_Sys`. This will cause the next step to be handled by the SimOS associated with the project, which will extract the syscall number from the state and query a specialized SimLibrary with that.

This deserves some explanation.

There is a subclass of SimLibrary called SimSyscallLibrary which is used for collecting all the functions that are part of an operating system's syscall interface. SimSyscallLibrary uses the same system for managing implementations and metadata as SimLibrary, but adds on top of it a system for managing syscall numbers for multiple ABIs (application binary interfaces, like an API but lower level). The best example for an implementation of a SimSyscallLibrary is the linux syscalls. It keeps its procedures in a normal SimProcedure catalog called `linux_kernel` and adds them to the library, then adds several syscall number mappings, including separate mappings for `mips-o32`, `mips-n32`, and `mips-n64`.

In order for syscalls to be supported in the first place, the project's SimOS must inherit from *SimUserland*, itself a SimOS subclass. This requires the class to call SimUserland's constructor with a super() call that includes the `syscall_library` keyword argument, specifying the specific SimSyscallLibrary that contains the appropriate procedures and mappings for the operating system. Additionally, the class's `configure_project` must perform a super()

call including the `abi_list` keyword argument, which contains the list of ABIs that are valid for the current architecture. If the ABI for the syscall can't be determined by just the syscall number, for example, that amd64 linux programs can use either `int 0x80` or `syscall` to invoke a syscall and these two ABIs use overlapping numbers, the SimOS cal override `syscall_abi()`, which takes a SimState and returns the name of the current syscall ABI. This is determined for int80/syscall by examining the most recent jumpkind, since libVEX will produce different syscall jumpkinds for the different instructions.

Calling conventions for syscalls are a little weird right now and they ought to be refactored. The current situation requires that `angr.SYSCALL_CC` be a map of maps `{arch_name: {os_name: cc_cls}}`, where `os_name` is the value of project.simos.name, and each of the calling convention classes must include an extra method called `syscall_number` which takes a state and return the current syscall number. Look at the bottom of calling_conventions.py to learn more about it. Not very object-oriented at all...

As a side note, each syscall is given a unique address in a special object in CLE called the "kernel object". Upon a syscall, the address for the specific syscall is set into the state's instruction pointer, so it will show up in the logs. These addresses are not hooked, they are just used to identify syscalls during analysis given only an address trace. The test for determining if an address corresponds to a syscall is `project.simos.is_syscall_addr(addr)` and the syscall corresponding to the address can be retrieved with `project.simos.syscall_from_addr(addr)`.

### Case 1, in-tree development

SimSyscallLibraries are stored in the same place as the normal SimLibraries, `angr/procedures/definitions`. These libraries don't have to specify any common name, but they can if they'd like to show up in `SIM_LIBRARIES` for easy access.

The same thing about adding procedures to existing catalogs of dynamic library functions also applies to syscalls - implementing a linux syscall is as easy as writing the SimProcedure and dropping the implementation into `angr/procedures/linux_kernel`. As long as the class name matches one of the names in the number-to-name mapping of the SimLibrary (all the linux syscall numbers are included with recent releases of angr), it will be used.

To add a new operating system entirely, you need to implement the SimOS as well, as a subclass of SimUserland. To integrate it into the tree, you should add it to the `simos` directory, but this is not a magic directory like `procedures`. Instead, you should add a line to `angr/simos/__init__.py` calling `register_simos()` with the OS name as it appears in `project.loader.main_object.os` and the SimOS class. Your class should do everything described above.

### Case 2, out-of-tree development, tight integration

You can add syscalls to a SimSyscallLibrary the same way you can add functions to a normal SimLibrary, by tweaking the entries in `angr.SIM_LIBRARIES`. If you're this for linux you want `angr.SIM_LIBRARIES['linux'][0].add(name, proc_cls)`.

You can register a SimOS with angr from out-of-tree as well - the same `register_simos` method is just sitting there waiting for you as `angr.simos.register_simos(name, simos_cls)`.

### Case 3, out-of-tree development, loose integration

The SimSyscallLibrary the SimOS uses is copied from the original during setup, so it is safe to mutate. You can directly fiddle with `project.simos.syscall_library` to manipulate an individual project's syscalls.

You can provide a SimOS class (not an instance) directly to the `Project` constructor via the `simos` keyword argument, so you can specify the SimOS for a project explicitly if you like.

### 6.3.4 SimData

What about when there is an import dependency on a data object? This is easily resolved when the given library is actually loaded into memory - the relocation can just be resolved as normal. However, when the library is not loaded (for example, `auto_load_libs=False`, or perhaps some dependency is simply missing), things get tricky. It is not possible to guess in most cases what the value should be, or even what its size should be, so if the guest program ever dereferences a pointer to such a symbol, emulation will go off the rails.

CLE will warn you when this might happen:

```
[22:26:58] [cle.backends.externs] |  WARNING: Symbol was allocated without a known size;␣
↪emulation will fail if it is used non-opaquely: _rtld_global
[22:26:58] [cle.backends.externs] |  WARNING: Symbol was allocated without a known size;␣
↪emulation will fail if it is used non-opaquely: __libc_enable_secure
[22:26:58] [cle.backends.externs] |  WARNING: Symbol was allocated without a known size;␣
↪emulation will fail if it is used non-opaquely: _rtld_global_ro
[22:26:58] [cle.backends.externs] |  WARNING: Symbol was allocated without a known size;␣
↪emulation will fail if it is used non-opaquely: _dl_argv
```

If you see this message and suspect it is causing issues (i.e. the program is actually introspecting the value of these symbols), you can resolve it by implementing and registering a SimData class, which is like a SimProcedure but for data. Simulated data. Very cool.

A SimData can effectively specify some data that must be used to provide an unresolved import symbol. It has a number of mechanisms to make this more useful, including the ability to specify relocations and subdependencies.

Look at the SimData `cle.backends.externs.simdata.SimData` class reference and the existing SimData subclasses for guidelines on how to do this.

## 6.4 Writing Analyses

An analysis can be created by subclassing the `angr.Analysis` class. In this section, we'll create a mock analysis to show off the various features. Let's start with something simple:

```
>>> import angr

>>> class MockAnalysis(angr.Analysis):
...     def __init__(self, option):
...         self.option = option

>>> angr.AnalysesHub.register_default('MockAnalysis', MockAnalysis) # register the class␣
↪with angr's global analysis list
```

This is a very simple analysis – it takes an option, and stores it. Of course, it's not useful, but this is just a demonstration.

Let's see how to run our new analysis:

```
>>> proj = angr.Project("/bin/true")
>>> mock = proj.analyses.MockAnalysis('this is my option')
>>> assert mock.option == 'this is my option'
```

### 6.4.1 Working with projects

Via some Python magic, your analysis will automatically have the project upon which you are running it under the `self.project` property. Use this to interact with your project and analyze it!

```
>>> class ProjectSummary(angr.Analysis):
...     def __init__(self):
...         self.result = 'This project is a %s binary with an entry point at %#x.' %␣
↪(self.project.arch.name, self.project.entry)

>>> angr.AnalysesHub.register_default('ProjectSummary', ProjectSummary)
>>> proj = angr.Project("/bin/true")

>>> summary = proj.analyses.ProjectSummary()
>>> print(summary.result)
This project is a AMD64 binary with an entry point at 0x401410.
```

### 6.4.2 Analysis Resilience

Sometimes, your (or our) code might suck and analyses might throw exceptions. We understand, and we also understand that oftentimes a partial result is better than nothing. This is specifically true when, for example, running an analysis on all of the functions in a program. Even if some of the functions fails, we still want to know the results of the functions that do not.

To facilitate this, the `Analysis` base class provides a resilience context manager under `self._resilience`. Here's an example:

```
>>> class ComplexFunctionAnalysis(angr.Analysis):
...     def __init__(self):
...         self._cfg = self.project.analyses.CFG()
...         self.results = { }
...         for addr, func in self._cfg.function_manager.functions.items():
...             with self._resilience():
...                 if addr % 2 == 0:
...                     raise ValueError("can't handle functions at even addresses")
...                 else:
...                     self.results[addr] = "GOOD"
```

The context manager catches any exceptions thrown and logs them (as a tuple of the exception type, message, and traceback) to `self.errors`. These are also saved and loaded when the analysis is saved and loaded (although the traceback is discarded, as it is not picklable).

You can tune the effects of the resilience with two optional keyword parameters to `self._resilience()`.

The first is `name`, which affects where the error is logged. By default, errors are placed in `self.errors`, but if `name` is provided, then instead the error is logged to `self.named_errors`, which is a dict mapping `name` to a list of all the errors that were caught under that name. This allows you to easily tell where thrown without examining its traceback.

The second argument is `exception`, which should be the type of the exception that `resilience` should catch. This defaults to `Exception`, which handles (and logs) almost anything that could go wrong. You can also pass a tuple of exception types to this option, in which case all of them will be caught.

Using `resilience` has a few advantages:

1. Your exceptions are gracefully logged and easily accessible afterwards. This is really nice for writing testcases.
2. When creating your analysis, the user can pass `fail_fast=True`, which transparently disable the resilience, which is really nice for manual testing.

3. It's prettier than having `try` `except` everywhere.

Have fun with analyses! Once you master the rest of angr, you can use analyses to understand anything computable!

CHAPTER

SEVEN

# ANGR EXAMPLES

To help you get started with angr, we've created several examples. We've tried to organize them into major categories, and briefly summarize that each example will expose you to. Enjoy!

If you want a high-level cheatsheet of the "techniques" used in the examples, see the angr strategies cheatsheet by Florent Bordignon.

To jump to a specific category:

- *Introduction* - examples showing off the very basics of angr's functionality
- *Reversing* - examples showing angr being used in reverse engineering tasks
- *Vulnerability Discovery* - examples of angr being used to search for vulnerabilities
- *Exploitation* - examples of angr being used as an exploitation assistance tool

## 7.1 Introduction

These are some introductory examples to give an idea of how to use angr's API.

### 7.1.1 Fauxware

This is a basic script that explains how to use angr to symbolically execute a program and produce concrete input satisfying certain conditions.

Binary, source, and script are found here.

## 7.2 Reversing

These are examples that use angr to solve reverse engineering challenges. There are a lot of these. We've chosen the most unique ones, and relegated the rest to the CTF Challenges section below.

### 7.2.1 Beginner reversing example: little_engine

```
Script author: Michael Reeves (github: @mastermjr)
Script runtime: 3 min 26 seconds (206 seconds)
Concepts presented:
stdin constraining, concrete optimization with Unicorn
```

This challenge is similar to the csaw challenge below, however the reversing is much more simple. The original code, solution, and writeup for the challenge can be found at the b01lers github here.

The angr solution script is here and the binary is here.

### 7.2.2 Whitehat CTF 2015 - Crypto 400

```
Script author: Yan Shoshitaishvili (github: @Zardus)
Script runtime: 30 seconds
Concepts presented: statically linked binary (manually hooking with function summaries),␣
↪commandline argument, partial solutions
```

We solved this crackme with angr's help. The resulting script will help you understand how angr can be used for crackme *assistance*, not a full-out solve. Since angr cannot solve the actual crypto part of the challenge, we use it just to reduce the keyspace, and brute-force the rest.

You can find this script here and the binary here.

### 7.2.3 CSAW CTF 2015 Quals - Reversing 500, "wyvern"

```
Script author: Audrey Dutcher (github: @rhelmot)
Script runtime: 15 mins
Concepts presented: stdin constraining, concrete optimization with Unicorn
```

angr can outright solve this challenge with very little assistance from the user. The script to do so is *here <https://github.com/angr/angr-examples/tree/master/examples/csaw_wyvern/solve.py>_* and the binary is here.

### 7.2.4 TUMCTF 2016 - zwiebel

```
Script author: Fish
Script runtime: 2 hours 31 minutes with pypy and Unicorn - expect much longer with␣
↪CPython only
Concepts presented: self-modifying code support, concrete optimization with Unicorn
```

This example is of a self-unpacking reversing challenge. This example shows how to enable Unicorn support and self-modification support in angr. Unicorn support is essential to solve this challenge within a reasonable amount of time - simulating the unpacking code symbolically is *very* slow. Thus, we execute it concretely in unicorn/qemu and only switch into symbolic execution when needed.

You may refer to other writeup about the internals of this binary. I didn't reverse too much since I was pretty confident that angr is able to solve it :-)

The long-term goal of optimizing angr is to execute this script within 10 minutes. Pretty ambitious :P

Here is the binary and the script.

### 7.2.5 FlareOn 2015 - Challenge 5

```
Script author: Adrian Tang (github: @tangabc)
Script runtime: 2 mins 10 secs
Concepts presented: Windows support
```

This is another reversing challenge from the FlareOn challenges.

"The challenge is designed to teach you about PCAP file parsing and traffic decryption by reverse engineering an executable used to generate it. This is a typical scenario in our malware analysis practice where we need to figure out precisely what the malware was doing on the network"

For this challenge, the author used angr to represent the desired encoded output as a series of constraints for the SAT solver to solve for the input.

For a detailed write-up please visit the author's post here and you can also find the solution from the FireEye here

### 7.2.6 0ctf quals 2016 - trace

```
Script author: WGH (wgh@bushwhackers.ru)
Script runtime: 1 min 50 secs (CPython 2.7.10), 1 min 12 secs (PyPy 4.0.1)
Concepts presented: guided symbolic tracing
```

In this challenge we're given a text file with trace of a program execution. The file has two columns, address and instruction executed. So we know all the instructions being executed, and which branches were taken. But the initial data is not known.

Reversing reveals that a buffer on the stack is initialized with known constant string first, then an unknown string is appended to it (the flag), and finally it's sorted with some variant of quicksort. And we need to find the flag somehow.

angr easily solves this problem. We only have to direct it to the right direction at every branch, and the solver finds the flag at a glance.

Files are here.

### 7.2.7 ASIS CTF Finals 2015 - license

```
Script author: Fish Wang (github: @ltfish)
Script runtime: 3.6 sec
Concepts presented: using the filesystem, manual symbolic summary execution
```

This is a crackme challenge that reads a license file. Rather than hooking the read operations of the flag file, we actually pass in a filesystem with the correct file created.

Here is the binary and the script.

### 7.2.8 DEFCON Quals 2017 - Crackme2000

```
Script author: Shellphish
Script runtime: varies, but on the order of seconds
Concepts presented: automated reverse engineering
```

DEFCON Quals had a whole category for automatic reversing in 2017. Our scripts are here.

## 7.3 Vulnerability Discovery

These are examples of angr being used to identify vulnerabilities in binaries.

### 7.3.1 Beginner vulnerability discovery example: strcpy_find

```
Script author: Kyle Ossinger (github: @k0ss)
Concepts presented: exploration to vulnerability, programmatic find condition
```

This is the first in a series of "tutorial scripts" I'll be making which use angr to find exploitable conditions in binaries. The first example is a very simple program. The script finds a path from the main entry point to `strcpy`, but **only** when we control the source buffer of the `strcpy` operation. To hit the right path, angr has to solve for a password argument, but angr solved this in less than 2 seconds on my machine using the standard Python interpreter. The script might look large, but that's only because I've heavily commented it to be more helpful to beginners. The challenge binary is here and the script is here.

### 7.3.2 CGC crash identification

```
Script author: Antonio Bianchi, Jacopo Corbetta
Concepts presented: exploration to vulnerability
```

This is a very easy binary containing a stack buffer overflow and an easter egg. CADET_00001 is one of the challenge released by DARPA for the Cyber Grand Challenge: link The binary can run in the DECREE VM: link A copy of the original challenge and the angr solution is provided here CADET_00001.adapted (by Jacopo Corbetta) is the same program, modified to be runnable in an Intel x86 Linux machine.

### 7.3.3 Grub "back to 28" bug

```
Script author: Audrey Dutcher (github: @rhelmot)
Concepts presented: unusual target (custom function hooking required), use of␣
↪exploration techniques to categorize and prune the program's state space
```

This is the demonstration presented at 32c3. The script uses angr to discover the input to crash grub's password entry prompt.

script - vulnerable module

## 7.4 Exploitation

These are examples of angr's use as an exploitation assistance engine.

### 7.4.1 Insomnihack Simple AEG

```
Script author: Nick Stephens (github: @NickStephens)
Concepts presented: automatic exploit generation, global symbolic data tracking
```

Demonstration for Insomni'hack 2016. The script is a very simple implementation of AEG.

script

### 7.4.2 SecuInside 2016 Quals - mbrainfuzz - symbolic exploration for exploitability conditions

```
Script author: nsr (nsr@tasteless.eu)
Script runtime: ~15 seconds per binary
Concepts presented: symbolic exploration guided by static analysis, using the CFG
```

Originally, a binary was given to the ctf-player by the challenge-service, and an exploit had to be crafted automatically. Four sample binaries, obtained during the ctf, are included in the example. All binaries follow the same format; the command-line argument is validated in a bunch of functions, and when every check succeeds, a memcpy() resulting into a stack-based buffer overflow is executed. angr is used to find the way through the binary to the memcpy() and to generate valid inputs to every checking function individually.

The sample binaries and the script are located here and additional information be found at the author's Write-Up.

### 7.4.3 SECCON 2016 Quals - ropsynth

```
Script author: Yan Shoshitaishvili (github @zardus) and Nilo Redini
Script runtime: 2 minutes
```

(continues on next page)

(continued from previous page)

```
Concepts presented: automatic ROP chain generation, binary modification, reasoning over␣
↪constraints, reasoning over action history
```

This challenge required the automatic generation of ropchains, with the twist that every ropchain was succeeded by an input check that, if not passed, would terminate the application. We used symbolic execution to recover those checks, removed the checks from the binary, used angrop to build the ropchains, and instrumented them with the inputs to pass the checks.

The various challenge files are located here, with the actual solve script here.

CHAPTER

EIGHT

# FREQUENTLY ASKED QUESTIONS

This is a collection of commonly-asked "how do I do X?" questions and other general questions about angr, for those too lazy to read this whole document.

If your question is of the form "how do I fix X issue after installing", see also the Troubleshooting section of the *install instructions*.

## 8.1 Why is it named angr?

The core of angr's analysis is on VEX IR, and when something is vexing, it makes you angry.

## 8.2 How should "angr" be stylized?

All lowercase, even at the beginning of sentences. It's an anti-proper noun.

## 8.3 Why isn't symbolic execution doing the thing I want?

The universal debugging technique for symbolic execution is as follows:

- Check your simulation manager for errored states. `print(simgr)` is a good place to start, and if you see anything to do with "errored", go for `print(simgr.errored)`.
- If you have any errored states and it's not immediately obvious what you did wrong, you can get a pdb shell at the crash site by going `simgr.errored[n].debug()`.
- If no state has reached an address you care about, you should check the path each state has gone down: `import pprint; pprint.pprint(state.history.descriptions.hardcopy)`. This will show you a high-level summary of what the symbolic execution engine did at each step along the state's history. You will be able to see from this a basic block trace and also a list of executed simprocedures. If you're using unicorn engine, you can check `state.history.bbl_addrs.hardcopy` to see what blocks were executed in each invocation of unicorn.
- If a state is going down the wrong path, you can check what constraints caused it to go that way: `print(state.solver.constraints)`. If a state has just gone past a branch, you can check the most recent branch condition with `state.history.events[-1]`.

## 8.4 How can I get diagnostic information about what angr is doing?

angr uses the standard `logging` module for logging, with every package and submodule creating a new logger.

The simplest way to get debug output is the following:

```
import logging
logging.getLogger('angr').setLevel('DEBUG')
```

You may want to use `INFO` or whatever else instead. By default, angr will enable logging at the `WARNING` level.

Each angr module has its own logger string, usually all the Python modules above it in the hierarchy, plus itself, joined with dots. For example, `angr.analyses.cfg`. Because of the way the Python logging module works, you can set the verbosity for all submodules in a module by setting a verbosity level for the parent module. For example, `logging.getLogger('angr.analyses').setLevel('INFO')` will make the CFG, as well as all other analyses, log at the INFO level.

## 8.5 Why is angr so slow?

It's complicated! *Optimization considerations*

## 8.6 How do I find bugs using angr?

It's complicated! The easiest way to do this is to define a "bug condition", for example, "the instruction pointer has become a symbolic variable", and run symbolic exploration until you find a state matching that condition, then dump the input as a testcase. However, you will quickly run into the state explosion problem. How you address this is up to you. Your solution may be as simple as adding an `avoid` condition or as complicated as implementing CMU's MAYHEM system as an Exploration Technique.

## 8.7 Why did you choose VEX instead of another IR (such as LLVM, REIL, BAP, etc)?

We had two design goals in angr that influenced this choice:

1. angr needed to be able to analyze binaries from multiple architectures. This mandated the use of an IR to preserve our sanity, and required the IR to support many architectures.
2. We wanted to implement a binary analysis engine, not a binary lifter. Many projects start and end with the implementation of a lifter, which is a time consuming process. We needed to take something that existed and already supported the lifting of multiple architectures.

Searching around the internet, the major choices were:

- LLVM is an obvious first candidate, but lifting binary code to LLVM cleanly is a pain. The two solutions are either lifting to LLVM through QEMU, which is hackish (and the only implementation of it seems very tightly integrated into S2E), or McSema, which only supported x86 at the time but has since gone through a rewrite and gotten support for x86-64 and aarch64.
- TCG is QEMU's IR, but extracting it seems very daunting as well and documentation is very scarce.
- REIL seems promising, but there is no standard reference implementation that supports all the architectures that we wanted. It seems like a nice academic work, but to use it, we would have to implement our own lifters, which we wanted to avoid.
- BAP was another possibility. When we started work on angr, BAP only supported lifting x86 code, and up-to-date versions of BAP were only available to academic collaborators of the BAP authors. These were two deal-breakers. BAP has since become open, but it still only supports x86_64, x86, and ARM.
- VEX was the only choice that offered an open library and support for many architectures. As a bonus, it is very well documented and designed specifically for program analysis, making it very easy to use in angr.

While angr uses VEX now, there's no fundamental reason that multiple IRs cannot be used. There are two parts of angr, outside of the `angr.engines.vex` package, that are VEX-specific:

- the jump labels (i.e., the `Ijk_Ret` for returns, `Ijk_Call` for calls, and so forth) are VEX enums.
- VEX treats registers as a memory space, and so does angr. While we provide accesses to `state.regs.rax` and friends, on the backend, this does `state.registers.load(8, 8)`, where the first `8` is a VEX-defined offset for `rax` to the register file.

To support multiple IRs, we'll either want to abstract these things or translate their labels to VEX analogues.

## 8.8 Why are some ARM addresses off-by-one?

In order to encode THUMB-ness of an ARM code address, we set the lowest bit to one. This convention comes from LibVEX, and is not entirely our choice! If you see an odd ARM address, that just means the code at `address - 1` is in THUMB mode.

## 8.9 How do I serialize angr objects?

Pickle will work. However, Python will default to using an extremely old pickle protocol that does not support more complex Python data structures, so you must specify a more advanced data stream format. The easiest way to do this is `pickle.dumps(obj, -1)`.

## 8.10 What does `UnsupportedIROpError("floating point support disabled")` mean?

This might crop up if you're using a CGC analysis such as driller or rex. Floating point support in angr has been disabled in the CGC analyses for a tight-knit nebula of reasons:

- Libvex's representation of floating point numbers is imprecise - it converts the 80-bit extended precision format used by the x87 for computation to 64-bit doubles, making it impossible to get precise results
- There is very limited implementation support in angr for the actual primitive operations themselves as reported by libvex, so you will often get a less friendly "unsupported operation" error if you go too much further
- For what operations are implemented, the basic optimizations that allow tractability during symbolic computation (AST deduplication, operation collapsing) are not implemented for floating point ops, leading to gigantic ASTs
- There are memory corruption bugs in z3 that get triggered frighteningly easily when you're using huge workloads of mixed floating point and bitvector ops. We haven't been able to get a testcase that doesn't involve "just run angr" for the z3 guys to investigate.

Instead of trying to cope with all of these, we have simply disabled floating point support in the symbolic execution engine. To allow for execution in the presence of floating point ops, we have enabled an exploration technique called the *https://github.com/angr/angr/blob/master/angr/exploration_techniques/oppologist.py <oppologist>* that is supposed to catch these issues, concretize their inputs, and run the problematic instructions through qemu via unicorn engine, allowing execution to continue. The intuition is that the specific values of floating point operations don't typically affect the exploitation process.

If you're seeing this error and it's terminating the analysis, it's probably because you don't have unicorn installed or configured correctly. If you're seeing this issue just in a log somewhere, it's just the oppologist kicking in and you have nothing to worry about.

## 8.11 Why is angr's CFG different from IDA's?

Two main reasons:

- IDA does not split basic blocks at function calls. angr will, because they are a form of control flow and basic blocks end at control flow instructions. You generally do not need the supergraph for performing automated analyses.
- IDA will split basic blocks if another block jumps into the middle of it. This is called basic block normalization, and angr does not do it by default since it is unnecessary for most static analyses. You may enable it by passing `normalize=True` to the CFG analysis.

## 8.12 Why do I get incorrect register values when reading from a state during a SimInspect breakpoint?

libVEX will eliminate duplicate register writes within a single basic block when optimizations are enabled. Turn off IR optimization to make everything look right at all times.

In the case of the instruction pointer, libVEX will frequently omit mid-block writes even when optimizations are disabled. In this case, you should use `state.scratch.ins_addr` to get the current instruction pointer.

CHAPTER

NINE

# APPENDIX

## 9.1 Cheatsheet

The following cheatsheet aims to give an overview of various things you can do with angr and act as a quick reference to check the syntax for something without having to dig through the deeper docs.

### 9.1.1 General getting started

Some useful imports

```
import angr # the main framework
from angr import claripy # the solver engine
```

Loading the binary

```
proj = angr.Project("/path/to/binary", auto_load_libs=False) # auto_load_libs False for␣
↪improved performance
```

### 9.1.2 States

Create a SimState object

```
state = proj.factory.entry_state()
```

### 9.1.3 Simulation Managers

Generate a simulation manager object

```
simgr = proj.factory.simulation_manager(state)
```

### 9.1.4 Exploring and analysing states

Choosing a different Exploring strategy

```
simgr.use_technique(angr.exploration_techniques.DFS())
```

Symbolically execute until we find a state satisfying our `find=` and `avoid=` parameters

```
avoid_addr = [0x400c06, 0x400bc7]
find_addr = 0x400c10d
simgr.explore(find=find_addr, avoid=avoid_addr)
```

```
found = simgr.found[0] # A state that reached the find condition from explore
found.solver.eval(sym_arg, cast_to=bytes) # Return a concrete string value for the sym
↪arg to reach this state
```

Symbolically execute until lambda expression is `True`

```
simgr.step(until=lambda sm: sm.active[0].addr >= first_jmp)
```

This is especially useful with the ability to access the current STDOUT or STDERR (1 here is the File Descriptor for STDOUT)

```
simgr.explore(find=lambda s: "correct" in s.posix.dumps(1))
```

Memory Management on big searches (Auto Drop Stashes):

```
simgr.explore(find=find_addr, avoid=avoid_addr, step_func=lambda lsm: lsm.drop(stash=
↪'avoid'))
```

#### Manually Exploring

```
simgr.step(step_func=step_func, until=lambda lsm: len(sm.found) > 0)

def step_func(lsm):
    lsm.stash(filter_func=lambda state: state.addr == 0x400c06, from_stash='active', to_
↪stash='avoid')
    lsm.stash(filter_func=lambda state: state.addr == 0x400bc7, from_stash='active', to_
↪stash='avoid')
    lsm.stash(filter_func=lambda state: state.addr == 0x400c10, from_stash='active', to_
↪stash='found')
    return lsm
```

Enable Logging output from Simulation Manager:

```
import logging
logging.getLogger('angr.sim_manager').setLevel(logging.DEBUG)
```

#### Stashes

Move Stash:

```
simgr.stash(from_stash="found", to_stash="active")
```

Drop Stashes:

```
simgr.drop(stash="avoid")
```

### 9.1.5 Constraint Solver (claripy)

Create symbolic object

```
sym_arg_size = 15 #Length in Bytes because we will multiply with 8 later
sym_arg = claripy.BVS('sym_arg', 8*sym_arg_size)
```

Restrict sym_arg to typical char range

```
for byte in sym_arg.chop(8):
    initial_state.add_constraints(byte >= '\x20') # ' '
    initial_state.add_constraints(byte <= '\x7e') # '~'
```

Create a state with a symbolic argument

```
argv = [proj.filename]
argv.append(sym_arg)
state = proj.factory.entry_state(args=argv)
```

Use argument for solving:

```
sym_arg = claripy.BVS("sym_arg", flag_size * 8)
argv = [proj.filename]
argv.append(sym_arg)
initial_state = proj.factory.full_init_state(args=argv, add_options=angr.options.unicorn,
↪ remove_options={angr.options.LAZY_SOLVES})
```

### 9.1.6 FFI and Hooking

Calling a function from ipython

```
f = proj.factory.callable(address)
f(10)
x=claripy.BVS('x', 64)
f(x) #TODO: Find out how to make that result readable
```

If what you are interested in is not directly returned because for example the function returns the pointer to a buffer you can access the state after the function returns with

```
>>> f.result_state
<SimState @ 0x1000550>
```

Hooking

There are already predefined hooks for libc functions (useful for statically compiled libraries)

```
proj = angr.Project('/path/to/binary', use_sim_procedures=True)
proj.hook(addr, angr.SIM_PROCEDURES['libc']['atoi']())
```

Hooking with Simprocedure:

```
class fixpid(angr.SimProcedure):
    def run(self):
            return 0x30

proj.hook(0x4008cd, fixpid())
```

### 9.1.7 Other useful tricks

Drop into an ipython if a ctr+c is received (useful for debugging scripts that are running forever)

```
import signal
def killmyself():
```

(continues on next page)

(continued from previous page)

```
    os.system('kill %d' % os.getpid())
def sigint_handler(signum, frame):
    print 'Stopping Execution for Debug. If you want to kill the program issue:␣
↪killmyself()'
    if not "IPython" in sys.modules:
        import IPython
        IPython.embed()

signal.signal(signal.SIGINT, sigint_handler)
```

Get the calltrace of a state to find out where we got stuck

```
state = simgr.active[0]
print state.callstack
```

Get a basic block

```
block = proj.factory.block(address)
block.capstone.pp() # Capstone object has pretty print and other data about the␣
↪disassembly
block.vex.pp()      # Print vex representation
```

### 9.1.8 State manipulation

Write to state:

```
aaaa = claripy.BVV(0x41414141, 32) # 32 = Bits
state.memory.store(0x6021f2, aaaa)
```

Read Pointer to Pointer from Frame:

```
poi1 = new_state.solver.eval(new_state.regs.rbp)-0x10
poi1 = new_state.mem[poi1].long.concrete
poi1 += 0x8
ptr1 = new_state.mem[poi1].long.concrete
```

Read from State:

```
key = []
for i in range(38):
    key.append(extractkey.mem[0x602140 + i*4].int.concrete)
```

Alternatively, the below expression is equivalent

```
key = extractkey.mem[0x602140].int.array(38).concrete
```

### 9.1.9 Debugging angr

Set Breakpoint at every Memory read/write:

```
new_state.inspect.b('mem_read', when=angr.BP_AFTER, action=debug_funcRead)
def debug_funcRead(state):
```

(continues on next page)

(continued from previous page)

```
    print 'Read', state.inspect.attrs.mem_read_expr, 'from', state.inspect.attrs.mem_
↪read_address
```

Set Breakpoint at specific Memory location:

```
new_state.inspect.b('mem_write', mem_write_address=0x6021f1, when=angr.BP_AFTER,␣
↪action=debug_funcWrite)
```

## 9.2 List of Claripy Operations

### 9.2.1 Arithmetic and Logic

| Name | Description | Example |
|---|---|---|
| LShR | Logically shifts an expression to the right. (the default shifts are arithmetic) | `x.LShR(10)` |
| RotateLeft | Rotates an expression left | `x.RotateLeft(8)` |
| RotateRight | Rotates an expression right | `x.RotateRight(8)` |
| And | Logical And (on boolean expressions) | `claripy.And(x == y, x > 0)` |
| Or | Logical Or (on boolean expressions) | `claripy.Or(x == y, y < 10)` |
| Not | Logical Not (on a boolean expression) | `claripy.Not(x == y)` is the same as `x != y` |
| If | An If-then-else | Choose the maximum of two expressions: `claripy.If(x > y, x, y)` |
| ULE | Unsigned less than or equal to | Check if x is less than or equal to y: `x.ULE(y)` |
| ULT | Unsigned less than | Check if x is less than y: `x.ULT(y)` |
| UGE | Unsigned greater than or equal to | Check if x is greater than or equal to y: `x.UGE(y)` |
| UGT | Unsigned greater than | Check if x is greater than y: `x.UGT(y)` |
| SLE | Signed less than or equal to | Check if x is less than or equal to y: `x.SLE(y)` |
| SLT | Signed less than | Check if x is less than y: `x.SLT(y)` |
| SGE | Signed greater than or equal to | Check if x is greater than or equal to y: `x.SGE(y)` |
| SGT | Signed greater than | Check if x is greater than y: `x.SGT(y)` |

**Todo**

Add the floating point ops

### 9.2.2 Bitvector Manipulation

| Name | Description | Example |
|---|---|---|
| SignExt | Pad a bitvector on the left with `n` sign bits | `x.sign_extend(n)` |
| ZeroExt | Pad a bitvector on the left with `n` zero bits | `x.zero_extend(n)` |
| Extract | Extracts the given bits (zero-indexed from the *right*, inclusive) from an expression. | Extract the least significant byte of x: `x[7:0]` |
| Concat | Concatenates any number of expressions together into a new expression. | `x.concat(y, ...)` |

### 9.2.3 Extra Functionality

There's a bunch of prepackaged behavior that you *could* implement by analyzing the ASTs and composing sets of operations, but here's an easier way to do it:

- You can chop a bitvector into a list of chunks of `n` bits with `val.chop(n)`
- You can endian-reverse a bitvector with `x.reversed`
- You can get the width of a bitvector in bits with `val.length`
- You can test if an AST has any symbolic components with `val.symbolic`
- You can get a set of the names of all the symbolic variables implicated in the construction of an AST with `val.variables`

## 9.3 List of State Options

### 9.3.1 State Modes

These may be enabled by passing `mode=xxx` to a state constructor.

| Mode name | Description |
|---|---|
| `symbolic` | The default mode. Useful for most emulation and analysis tasks. |
| `symbolic_appr` | Symbolic mode, but enables approximations for constraint solving. |
| `static` | A preset useful for static analysis. The memory model becomes an abstract region-mapping system, "fake return" successors skipping calls are added, and more. |
| `fastpath` | A preset for extremely lightweight static analysis. Executing will skip all intensive processing to give a quick view of the behavior of code. |
| `tracing` | A preset for attempting to execute concretely through a program with a given input. Enables unicorn, enables resilience options, and will attempt to emulate access violations correctly. |

### 9.3.2 Option Sets

These are sets of options, found as `angr.options.xxx`.

| Set name | Description |
|---|---|
| `common_o` | Options necessary for basic execution |
| `symbolic` | Options necessary for basic symbolic execution |
| `resilien` | Options that harden angr's emulation against unsupported operations, attempting to carry on by treating the result as an unconstrained symbolic value and logging the occasion to `state.history.events`. |
| `refs` | Options that cause angr to keep a log of all the memory, register, and temporary references complete with dependency information in `history.actions`. This option consumes a lot of memory, so be careful! |
| `approxim` | Options that enable approximations of constraint solves via value-set analysis instead of calling into z3 |
| `simplifi` | Options that cause data to be run through z3's simplifiers before it reaches memory or register storage |
| `unicorn` | Options that enable the unicorn engine for executing on concrete data |

### 9.3.3 Options

These are individual option objects, found as `angr.options.XXX`.

| Option name | Description | Sets | Modes | Implicit adds |
|---|---|---|---|---|
| ABSTRACT_MEMORY | Use SimAbstractMemory to model memory as discrete regions | | static | |
| ABSTRACT_SOLVER | Allow splitting constraint sets during simplification | | static | |
| ACTION_DEPS | Track dependencies in SimActions | | | |
| APPROXIMATE_GUARD | Use VSA when evaluating guard conditions | | | |
| APPROXIMATE_MEMOR | Use VSA when evaluating memory indices | approximation | symbolic_approxim | |
| APPROXIMATE_MEMOR | Use VSA when evaluating memory load/store sizes | approximation | symbolic_approxim | |
| APPROXIMATE_SATIS | Use VSA when evaluating state satisfiability | approximation | symbolic_approxim | |
| AST_DEPS | Enables dependency tracking for all claripy ASTs | | | During execution |
| AUTO_REFS | An internal option used to track dependencies in SimProcedures | | | During execution |
| AVOID_MULTIVALUED | Return a symbolic value without touching memory for any read that has a symbolic address | | fastpath | |
| AVOID_MULTIVALUED | Do not perform any write that has a symbolic address | | fastpath | |
| BEST_EFFORT_MEMOR | Handle huge writes of symbolic size by pretending they are actually smaller | | static, fastpath | |
| BREAK_SIRSB_END | Debug: trigger a breakpoint at the end of each block | | | |
| BREAK_SIRSB_START | Debug: trigger a breakpoint at the start of each block | | | |

continues on next page

Table 1 – continued from previous page

| Option name | Description | Sets | Modes | Implicit adds |
|---|---|---|---|---|
| BREAK_SIRSTMT_END | Debug: trigger a breakpoint at the end of each IR statement | | | |
| BREAK_SIRSTMT_STA | Debug: trigger a breakpoint at the start of each IR statement | | | |
| BYPASS_ERRORED_IR | Treat clean helpers that fail with errors as returning unconstrained symbolic values | resilience | fastpath, tracing | |
| BYPASS_ERRORED_IR | Treat operations that fail with errors as returning unconstrained symbolic values | resilience | fastpath, tracing | |
| BYPASS_UNSUPPORTE | Treat unsupported clean helpers as returning unconstrained symbolic values | resilience | fastpath, tracing | |
| BYPASS_UNSUPPORTE | Treat unsupported dirty helpers as returning unconstrained symbolic values | resilience | fastpath, tracing | |
| BYPASS_UNSUPPORTE | Treat unsupported IR expressions as returning unconstrained symbolic values | resilience | fastpath, tracing | |
| BYPASS_UNSUPPORTE | Treat unsupported operations as returning unconstrained symbolic values | resilience | fastpath, tracing | |
| BYPASS_UNSUPPORTE | Treat unsupported IR statements as returning unconstrained symbolic values | resilience | fastpath, tracing | |
| BYPASS_UNSUPPORTE | Treat unsupported syscalls as returning unconstrained symbolic values | resilience | fastpath, tracing | |
| BYPASS_VERITESTIN | Discard emulation errors during veritesting | resilience | fastpath, tracing | |
| CACHELESS_SOLVER | enable SolverCacheless | | | |

continues on next page

Table 1 – continued from previous page

| Option name | Description | Sets | Modes | Implicit adds |
|---|---|---|---|---|
| CALLLESS | Emulate call instructions as an unconstraining of the return value register | | | |
| CGC_ENFORCE_FD | CGC: make sure all reads and writes go to stdin and stdout, respectively | | | |
| CGC_NON_BLOCKING_ | CGC: always report "data available" in fdwait | | | |
| CGC_NO_SYMBOLIC_R | CGC: always read the maximum amount of data requested in the receive syscall | | | |
| COMPOSITE_SOLVER | Enable SolverComposite for independent constraint set optimization | symbolic | all except static | |
| CONCRETIZE | Concretize all symbolic expressions encountered during emulation | | | |
| CONCRETIZE_SYMBOL | Concreteize the sizes of file reads | | | |
| CONCRETIZE_SYMBOL | Concretize the sizes of symbolic writes to memory | | | |
| CONSERVATIVE_READ | Do not use SimConcretizationStrategyAny for reads; in case of read address concretization failures, return an unconstrained symbolic value | | | |
| CONSERVATIVE_WRIT | Do not use SimConcretizationStrategyAny for writes; in case of write address concretization failures, treat the store as a no-op | | | |
| CONSTRAINT_TRACKI | Set track=True for making claripy Solvers; enable use of unsat_core | | | |

continues on next page

Table 1 – continued from previous page

| Option name | Description | Sets | Modes | Implicit adds |
|---|---|---|---|---|
| COW_STATES | Copy states instead of mutating the initial state directly | common_options | all | |
| DOWNSIZE_Z3 | Downsize the claripy solver whenever possible to save memory | | | |
| DO_CCALLS | Perform IR clean calls | symbolic | all except fastpath | |
| DO_GETS | Perform IR register reads | common_options | all | |
| DO_LOADS | Perform IR memory loads | common_options | all | |
| DO_OPS | Perform IR computation operations | common_options | all | |
| DO_PUTS | Perform IR register writes | common_options | all | |
| DO_RET_EMULATION | For each Ijk_Call successor, add a corresponding Ijk_FakeRet successor | | static, fastpath | |
| DO_STORES | Perform IR memory stores | common_options | all | |
| EFFICIENT_STATE_M | Keep in memory any state that might be a common ancestor in a merge | | | Veritesting |
| ENABLE_NX | When in conjunction with STRICT_PAGE_ACCES raise a SimSegfaultException on executing non-executable memory | | | Automatically if supported |
| EXCEPTION_HANDLIN | Ask all SimExceptions raised during execution to be handled by the SimOS | | tracing | |
| FAST_MEMORY | Use SimFastMemory for memory storage | | | |
| FAST_REGISTERS | Use SimFastMemory for register storage | | fastpath | |
| INITIALIZE_ZERO_R | Treat the initial value of registers as zero instead of unconstrained symbolic | unicorn | tracing | |

continues on next page

Table 1 – continued from previous page

| Option name | Description | Sets | Modes | Implicit adds |
|---|---|---|---|---|
| KEEP_IP_SYMBOLIC | Don't try to concretize successor states with symbolic instruction pointers | | | |
| KEEP_MEMORY_READS | In abstract memory, handle failed loads by returning a DCIS? | | | |
| LAZY_SOLVES | Don't check satisfiability until absolutely necessary | | | |
| MEMORY_SYMBOLIC_B | Maintain a mapping of symbolic variable to which memory address it "really" corresponds to, at the paged memory level? | | | |
| NO_SYMBOLIC_JUMP_ | Do not attempt to flatten symbolic-ip successors into discrete targets | | fastpath | |
| NO_SYMBOLIC_SYSCA | Do not attempt to flatten symbolic-syscall-number successors into discrete targets | | fastpath | |
| OPTIMIZE_IR | Use LibVEX's optimization | common_options | all | |
| REGION_MAPPING | Maintain a mapping of symbolic variable to which memory region it corresponds to, at the abstract memory level | | static | |
| REPLACEMENT_SOLVE | Enable SolverReplacement | | | |
| REVERSE_MEMORY_HA | Maintain a mapping from AST hash to which addresses it is present in | | | |
| REVERSE_MEMORY_NA | Maintain a mapping from symbolic variable name to which addresses it is present in, required for memory.replace_all | | static | |

continues on next page

Table 1 – continued from previous page

| Option name | Description | Sets | Modes | Implicit adds |
|---|---|---|---|---|
| SIMPLIFY_CONSTRAI | Run added constraints through z3's simplifcation | | | |
| SIMPLIFY_EXIT_GUA | Run branch guards through z3's simplification | | | |
| SIMPLIFY_EXIT_STA | Perform simplification on all successor states generated | | | |
| SIMPLIFY_EXIT_TAR | Run jump/call/branch targets through z3's simplification | | | |
| SIMPLIFY_EXPRS | Run the results of IR expressions through z3's simplification | | | |
| SIMPLIFY_MEMORY_R | Run the results of memory reads through z3's simplification | | | |
| SIMPLIFY_MEMORY_W | Run values stored to memory through z3's simplification | simplification, common_options | symbolic, symbolic_approxim tracing | |
| SIMPLIFY_REGISTER | Run values read from registers through z3's simplification | | | |
| SIMPLIFY_REGISTER | Run values written to registers through z3's simplification | simplification, common_options | symbolic, symbolic_approxim tracing | |
| SIMPLIFY_RETS | Run values returned from SimProcedures through z3's simplification | | | |
| STRICT_PAGE_ACCES | Raise a SimSegfaultException when attempting to interact with memory in a way not permitted by the current permissions | | tracing | |
| SUPER_FASTPATH | Only execute the last four instructions of each block | | | |
| SUPPORT_FLOATING_ | When disabled, throw an UnsupportedIROpError when encountering floating point operations | common_options | all | |

continues on next page

Table 1 – continued from previous page

| Option name | Description | Sets | Modes | Implicit adds |
|---|---|---|---|---|
| SYMBOLIC | Enable constraint solving? | symbolic | symbolic, symbolic_approxim fastpath | |
| SYMBOLIC_INITIAL_ | make state.solver.Unconstrained return a symbolic value instead of zero | symbolic | all | |
| SYMBOLIC_TEMPS | Treat each IR temporary as a symbolic variable; treat stores to them as constraint addition | | | |
| SYMBOLIC_WRITE_AD | Allow writes with symbolic addresses to be processed by concretization strategies; when disabled, only allow for variables annotated with the "multiwrite" annotation | | | |
| TRACK_CONSTRAINTS | When disabled, don't keep any constraints added to the state | symbolic | all | |
| TRACK_CONSTRAINT_ | Keep a SimAction for each constraint added | refs | | |
| TRACK_JMP_ACTIONS | Keep a SimAction for each jump or branch | refs | | |
| TRACK_MEMORY_ACTI | Keep a SimAction for each memory read and write | refs | | |
| TRACK_MEMORY_MAPP | Keep track of which pages are mapped into memory and which are not | common_options | all | |
| TRACK_OP_ACTIONS | Keep a SimAction for each IR operation | | fastpath | |
| TRACK_REGISTER_AC | Keep a SimAction for each register read and write | refs | | |
| TRACK_SOLVER_VARI | Maintain a listing of all the variables in all the constraints in the solver | | | |

continues on next page

Table 1 – continued from previous page

| Option name | Description | Sets | Modes | Implicit adds |
|---|---|---|---|---|
| TRACK_TMP_ACTIONS | Keep a SimAction for each temporary variable read and write | refs | | |
| TRUE_RET_EMULATIC | With DO_RET_EMULATION, add fake returns with guard condition true instead of false | | static | |
| UNDER_CONSTRAINED | Enable under-constrained symbolic execution | | | |
| UNICORN | Use unicorn engine to execute symbolically when data is concrete | unicorn | tracing | Oppologist |
| UNICORN_AGGRESSIV | Concretize any register variable unicorn tries to access | | | Oppologist |
| UNICORN_HANDLE_TR | CGC: handle the transmit syscall without leaving unicorn | unicorn | tracing | |
| UNICORN_SYM_REGS_ | Attempt to stay in unicorn even in the presence of symbolic registers by checking that the tainted registers are unused at every step | unicorn | tracing | |
| UNICORN_THRESHOLD | Concretize variables if they prevent unicorn from executing too often | | | |
| UNICORN_TRACK_BBL | Keep state.history.bbl_addrs up to date when using unicorn | unicorn | tracing | |
| UNICORN_TRACK_STA | Track a list of the stack pointer's value at each block in state.scratch.stack_pointer_lis | unicorn | | |
| UNICORN_ZEROPAGE_ | Prevent unicorn from mapping the zero page into memory | | | |

continues on next page

Table 1 – continued from previous page

| Option name | Description | Sets | Modes | Implicit adds |
|---|---|---|---|---|
| UNINITIALIZED_ACC | Broken/unused? | | | |
| UNSUPPORTED_BYPAS | When using the resilience options, return zero instead of an unconstrained symbol | | | |
| USE_SIMPLIFIED_CC | Use a "simplified" set of ccalls optimized for specific cases | | static | |
| USE_SYSTEM_TIMES | In library functions and syscalls and hardware instructions accessing clock data, retrieve the real value from the host system. | | tracing | |
| VALIDATE_APPROXIM | Debug: When performing approximations, ensure that the approximation is sound by calling into z3 | | | |
| ZERO_FILL_UNCONSTI | Make the value of memory read from an uninitialized address zero instead of an unconstrained symbol | | tracing | |

## 9.4 CTF Challenge Examples

angr is very often used in CTFs. These are example scripts resulting from that use, mostly from Shellphish but also from many others.

### 9.4.1 ReverseMe example: HackCon 2016 - angry-reverser

Script author: Stanislas Lejay (github: @P1kachu)

Script runtime: ~31 minutes

Here is the binary and the script

### 9.4.2 ReverseMe example: SecurityFest 2016 - fairlight

Script author: chuckleberryfinn (github: @chuckleberryfinn)

Script runtime: ~20 seconds

A simple reverse me that takes a key as a command line argument and checks it against 14 checks. Possible to solve the challenge using angr without reversing any of the checks.

Here is the binary and the script

### 9.4.3 ReverseMe example: DEFCON Quals 2016 - baby-re

Authors David Manouchehri (github: @Manouchehri), Stanislas Lejay (github: @P1kachu) and Audrey Dutcher (github: @rhelmot).

Script runtime: 10 sec

Here is the binary and the script

### 9.4.4 ReverseMe example: Google CTF - Unbreakable Enterprise Product Activation (150 points)

Script 0 author: David Manouchehri (github: @Manouchehri)

Script runtime: 4.5 sec

Script 1 author: Adam Van Prooyen (github: @docileninja)

Script runtime: 6.7 sec

A Linux binary that takes a key as a command line argument and checks it against a series of constraints.

Challenge Description:

> We need help activating this product – we've lost our license key :(
>
> You're our only hope!

Here are the binary and scripts: script 0, script_1

### 9.4.5 ReverseMe example: EKOPARTY CTF - Fuckzing reverse (250 points)

Author: Adam Van Prooyen (github: @docileninja)

Script runtime: 29 sec

A Linux binary that takes a team name as input and checks it against a series of constraints.

Challenge Description:

> Hundreds of conditions to be meet, will you be able to surpass them?

Both sample binaries and the script are located here and additional information be found at the author's write-up.

### 9.4.6 ReverseMe example: WhiteHat Grant Prix Global Challenge 2015 - Re400

Author: Fish Wang (github: @ltfish)

Script runtime: 5.5 sec

A Windows binary that takes a flag as argument, and tells you if the flag is correct or not.

"I have to patch out some checks that are difficult for angr to solve (e.g., it uses some bytes of the flag to decrypt some data, and see if those data are legit Windows APIs). Other than that, angr works really well for solving this challenge."

The binary and the script.

### 9.4.7 ReverseMe example: EKOPARTY CTF 2015 - rev 100

Author: Fish Wang (github: @ltfish)

Script runtime: 5.5 sec

This is a painful challenge to solve with angr. I should have done things in a smarter way.

Here is the binary and the script.

### 9.4.8 ReverseMe example: ASIS CTF Finals 2015 - fake

Author: Fish Wang (github: @ltfish)

Script runtime: 1 min 57 sec

The solution is pretty straight-forward.

The binary and the script.

### 9.4.9 ReverseMe example: Defcamp CTF Qualification 2015 - Reversing 100

Author: Fish Wang (github: @ltfish)

angr solves this challenge with almost zero user-interference.

See the script and the binary.

### 9.4.10 ReverseMe example: Defcamp CTF Qualification 2015 - Reversing 200

Author: Fish Wang (github: @ltfish)

angr solves this challenge with almost zero user-interference. Veritesting is required to retrieve the flag promptly.

The script and the binary. It takes a few minutes to run on my laptop.

### 9.4.11 ReverseMe example: MMA CTF 2015 - HowToUse

Author: Audrey Dutcher (github: @rhelmot)

We solved this simple reversing challenge with angr, since we were too lazy to reverse it or run it in Windows. The resulting script shows how we grabbed the flag out of the DLL.

### 9.4.12 CrackMe example: MMA CTF 2015 - SimpleHash

Author: Chris Salls (github: @salls)

This crackme is 95% solvable with angr, but we did have to overcome some difficulties. The script describes the difficulties that were encountered and how we worked around them. The binary can be found here.

### 9.4.13 ReverseMe example: FlareOn 2015 - Challenge 10

Author: Fish Wang (github: @ltfish)

angr acts as a binary loader and an emulator in solving this challenge. I didn't have to load the driver onto my Windows box.

The script demonstrates how to hook at arbitrary program points without affecting the intended bytes to be executed (a zero-length hook). It also shows how to read bytes out of memory and decode as a string.

By the way, here is the link to the intended solution from FireEye.

### 9.4.14 ReverseMe example: FlareOn 2015 - Challenge 2

Author: Chris Salls (github: @salls)

This reversing challenge is simple to solve almost entirely with angr, and a lot faster than trying to reverse the password checking function. The script is here

### 9.4.15 ReverseMe example: 0ctf 2016 - momo

Author: Fish Wang (github: @ltfish), ocean (github: @ocean1)

This challenge is a movfuscated binary. To find the correct password after exploring the binary with Qira it is possible to understand how to find the places in the binary where every character is checked using capstone and using angr to load the binary and brute-force the single characters of the flag. Be aware that the script is really slow. Runtime: > 1 hour.

### 9.4.16 CrackMe example: 9447 CTF 2015 - Reversing 330, "nobranch"

Author: Audrey Dutcher (github: @rhelmot)

angr cannot currently solve this problem natively, as the problem is too complex for z3 to solve. Formatting the constraints to z3 a little differently allows z3 to come up with an answer relatively quickly. (I was asleep while it was solving, so I don't know exactly how long!) The script for this is here and the binary is here.

### 9.4.17 CrackMe example: ais3_crackme

Author: Antonio Bianchi, Tyler Nighswander

ais3_crackme has been developed by Tyler Nighswander (tylerni7) for ais3 summer school. It is an easy crackme challenge, checking its command line argument.

### 9.4.18 ReverseMe: Modern Binary Exploitation - CSCI 4968

Author: David Manouchehri (GitHub @Manouchehri)

This folder contains scripts used to solve some of the challenges with angr. At the moment it only contains the examples from the IOLI crackme suite, but eventually other solutions will be added.

### 9.4.19 CrackMe example: Android License Check

Author: Bernhard Mueller (GitHub @b-mueller)

A native binary for Android/ARM that validates a license key passed as a command line argument. It was created for the symbolic execution tutorial in the OWASP Mobile Testing Guide.

## 9.5 Changelog

This lists the *major* changes in angr. Tracking minor changes are left as an exercise for the reader :-)

### 9.5.1 angr 9.1

- (#2961) Refactored SimCC to support passing and returning structs and arrays by value
- (#2964) Functions from the knowledge base may now be pretty-printed, showing colors and reference arrows
- Improved `import angr` speed substantially
- (#2948) RDA's `dep_graph` can now be used to track dependencies between temporaries, constants, guard conditions, and function calls - if you want it!
- (#2929) Basic support for structs with bitfields in SimType
- There's a decompiler now

### 9.5.2 angr 9.0

- Switched to a new versioning scheme: major.minor.build_id

### 9.5.3 angr 8.19.7.25

- (#1503) Implement necessary helpers and information storage for call pretty printing
- (#1546) Add a new state option MEMORY_FIND_STRICT_SIZE_LIMIT
- (#1548) SimProcedure.static_exits: Allow providing name hints
- (cle#177) Use Enums for Symbol Types
- (cle#193) Add support for "named regions"
- (claripy#151) Implement operator precedence in claripy op rendering
- Added support for interaction recording in angr-management
- Several new simprocedure implementations
- Substantial imporvments to our CFG

### 9.5.4 angr 8.19.4.5

- (#1234) Massive improvements to CFG recovery for ARM and ARM cortex-m binaries.
- (#1416) Added support for analyzing Java programs via the Soot IR, including the ability to analyze interplay between Java code and JNI libraries. This branch was two years old!
- (#1427) Added a MemoryWatcher exploration technique to take action when the system is running out of RAM. Thanks @bannsec.
- (#1432) Added a `state.heap` plugin which manages the heap (with pluggable heap schemes!) and provides malloc functionality. Thanks @tgduckworth.
- Speed improvements for using the VEX engine and working with concrete data.
- Added SimLightRegisters, an alternate registers plugin that eliminates the abstraction of the register file for performance improvements at the cost of removing all instrumentability.
- `version__` variable has been added to all modules.
- The `stack_base` kwarg for `call_state` is not broken for the first time ever
- https://github.com/python/cpython/pull/11384

### 9.5.5 angr 8.19.2.4

- (#1279) Support C++ function name demangling via itanium-demangler. Thanks @fmagin.
- (#1283) `security_cookie` is initialized for SimWindows. Thanks @zeroSteiner.
- (#1298) Introduce `SimData`. It's a cleaner interface to deal with data imports in CLE – especially for those data entries that are not imported because of missing or unloaded libraries. This commit fixes long-standing issues #151 and #693.
- (#1299, #1300, #1301, #1313, #1314, #1315, #1336, #1337, #1343, ...) Multiple CFGFast-related improvements and bug fixes.
- (#1332) `UnresolvableTarget` is now split into two classes: `UnresolvableJumpTarget` and `UnresolvableCallTarget`. Thanks @Kyle-Kyle.

- (#1382) Add a preliminary implementation of angr decompiler. Give it a try! `p = angr.Project("cfg_loop_unrolling", auto_load_libs=False); p.analyses.CFG(); print(p.analyses.Decompiler(p.kb.functions['test_func']).codegen.text)`.
- (#1421) `SimActions` now have incrementing IDs. Thanks @bannsec.
- (#1408) `ANA`, angr's old identity-aware serialization backend, has been removed. Instead of non-obvious serialization behavior, all angr objects should now be pickleable. If one is not, please file an issue. For use-cases that require identity-awareness (i.e., deduplicating ASTs across states serialized at different times), an `angr.vaults` module has been introduced.
- Added a facility to synchronize state between angr and a running target a la avatar2
- Changed unconstrained registers/memory warning to be less obnoxious and contain useful information. Also added `SYMBOL_FILL_UNCONSTRAINED_REGISTERS` and `SYMBOL_FILL_UNCONSTRAINED_MEMORY` state options to silence them.

### 9.5.6 angr 8.18.10.25

- The IDA backend for CLE has been removed. It has been broken for quite some time, but now it has been disabled for your own safety.
- Surveyors have been removed! Finally! This is thanks to @danse-macabre who contributed an Exploration Technique for the Slicecutor. Backwards slicing has now been brought out of the angr dark ages.
- SimCC can now be initialized with a string containing C function prototype in its `func_ty` argument
- Similarly, Callable can now be run with its arguments instantiated from a string containing C expressions
- Tracer has been substantially refactored - it will now handle more kinds of desyncs, ASLR slides, and is much more friendly for hacking. We will be continuing to improve it!
- The Oppologist and Driller have been refactored to play nice with other exploration techniques
- SimProcedure continuations now have symbols in the externs object, so `describe_addr` will work on them. Additionally, the representation for SimProcedure (appearing in `history.descriptions` and `project._sim_procedures` among other places) has been improved to show this information.

### 9.5.7 angr 8.18.10.5

Largely a bugfix release, but with a few bonus treats:

- API documentation has been rewritten for Exploration Technique. It should be much easier to use now.
- Simulation Manager will throw an error if you pass incorrect keyword arguments (??? why was it like this)
- The `save_unconstrained` flag of Simulation Manager is now on by default
- If a step produces only unsatisfiable states, they will appear in the `'unsat'` stash regardless of the `save_unsat` setting, since this usually indicates a bug. Add `unsat` to the `auto_drop` parameter to restore the old behavior.

### 9.5.8 angr 8.18.10.1

Welcome to angr 8! The biggest change for this major version bump is the transition to Python 3. You can read about this, as well as a few other breaking changes, in the *Migrating to angr 8*.

- Switch to Python 3
- Refactor to Clemory to clean up the API and speed things up drastically
- Remove `object.symbols_by_addr` (dict) and add `object.symbols` (sorted list); add `fuzzy` parameter to `loader.find_symbol`

- CFGFast is much, much faster now. CFGAccurate has been renamed to CFGEmulated.
- Support for avx2 unpack instructions, courtesy of D. J. Bernstein
- Removed support for immutable simulation managers
- angr will now show you a warning when using uninitialized memory or registers
- angr will now NOT show you a warning if you have a capstone 3.x install unless you're actually interacting with the relevant missing parts
- Many, many, many bug fixes

### 9.5.9 angr 7.8.7.1

- Remove `LoopLimiter` and `DFG`.
- (#1063) `CFGAccurate` can now leverage indirect jump resolvers to resolve indirect jumps.

### 9.5.10 angr 7.8.6.23

- (PyVEX!#134) We now recognize LDMDB r11, {xxx, pc} as a ret instruction for ARM.
- (#1053) CFGFast spends less time running next_pos_with_sort_not_in(), thus it runs faster on large binaries.
- (#1080) Jump table resolvers now support resolving ARM jump tables.
- (#1081, together with the PyVEX commit 61efbdcf6303a936aa3de35011d2d1e3fe5fdea5) The memory footprint of CFGFast is noticeably smaller, especially on large binaries (over 10 MB in size).
- (#1034) Concretizing a SimFile with unconstrained size can no longer run you out of memory.
- Other minor changes and bug fixes.

### 9.5.11 angr 7.8.6.16

- The modeling of file system is refactored.
- (#808) Add a new class Control flow blanket (CFBlanket) to support generating a linear view of a control flow graph.
- (#863) Add support to AIL, the new angr intermediate language (still pretty WIP though). Merged in several static analyses (reaching definition analysis, VEX-to-AIL translation, redundant assignment elimination, code region identification, control flow structuring, etc.) that support the development of decompilation in the near future.
- (#888) SimulationManager is extensively refactored and cleaned up.
- (#892) Keystone is integrated. You can assemble instructions inside angr now.
- (#897) A new class `PluginHub` is added. Plugins (analyses, engines) are refactored to be based on `PluginHub`.
- (#899) Support of bidirectional mapping between syscall numbers and syscalls.
- (#925, #941, #942) A bunch of library function prototypes (including glibc) are added to angr.
- (#953) Fix the issue where evaluating the jump target of a jump table that contains many entries (e.g., > 512) is extremely slow.
- (#964) State options are now stored in insances of SimStateOptions. `state.options` is no longer a set of strings.
- (#973) Add two new exploration techniques: Stochastic and unique.
- (#996) SimType structs are now much easier to use.
- (#998) Add a new state option `PRODUCE_ZERODIV_SUCCESSORS` to generate divide-by-zero successors.

- Speed improvements and bug fixes in CFG generation (CFGFast and CFGAccurate).

### 9.5.12 angr 7.8.2.21

- Refactor of how syscall handling and SimSyscallLibrary work - it is now possible to handle syscalls using multiple ABIs in the same process
- Added syscall name-number mappings from all linux ABIs, parsed from gdb
- Add `ManualMergepoint` exploration technique for when veritesting is too mysterious for your tastes
- Add `LoopSeer` exploration technique for managing loops during symbolic exploration (credit @tyb0807)
- Add `ProxyTechnique` exploration technique for easily composing simple lambda-based instrumentations (credit @danse-macabre)

### 9.5.13 angr 7.7.12.16

- You can now tell where the variables implicitly created by angr come from! `state.solver.BVS` now can take a `key` parameter, which describes its meaning in relation to the emulated environment. You can then use `state.solver.get_variables(...)` and `state.solver.describe_variables(...)` to map tags and ASTs to and from each other. Check out the API docs!
- The SimOS for a project is now a public property - `project.simos` instead of `project._simos`. Additionally, the SimOS code structure has been shuffled around a bit - it's now a subpackage instead of a submodule.
- The core components of Tracer and Driller have been refactored into Exploration Techniques and integrated into angr proper, so you can now follow instruction traces without installing another repository! (credit @tyb0807)
- Archinfo now contains a `byte_width` parameter and angr supports emulation of platforms with non-octet bytes, lord help us
- Upgraded to networkx 2 (credit @tyb0807)
- Hopefully installation issues with capstone should be fixed FOREVER
- Minor fixes to gender

### 9.5.14 angr 7.7.9.8

Welcome to angr 7! We worked long and hard all summer to make this release the best ever. It introduces several breaking changes, so for a quick guide on the most common ways you'll need to update your scripts, take a look at the *Migrating to angr 7*.

- SimuVEX has been removed and its components have been integrated into angr
- Path has been removed and its components have been integrated into SimState, notably the new `history` state plugin
- PathGroup has been renamed to SimulationManager
- SimState and SimProcedure now have a reference to their parent Project, though it is verboten to use it in anything other than an append-only fashion
- A new class SimLibrary is used to track SimProcedure and metadata corresponding to an individual shared library
- Several CLE interfaces have been refactored up for consistency
- Hook has been removed. Hooking is now done with individual SimProcedure instances, which are shallow-copied at execution time for thread-safety.
- The `state.solver` interface has been cleaned up drastically

These are the major refactor-y points. As for the improvements:

- Greatly improved support for analyzing 32 bit windows binaries (partial credit @schieb)
- Unicorn will now stop for stop points and breakpoints in the middle of blocks (credit @bennofs)
- The processor flags for a state can now be accessed through `state.regs.eflags` on x86 and `state.regs.flags` on ARM (partial credit @tyb0807)
- Fledgling support for emulating exception handling. Currently the only implementation of this is support for Structured Exception Handling on Windows, see `angr.SimOS.handle_exception` for details
- Fledgling support for runtime library loading by treating the CLE loader as an append-only interface, though only implemented for windows. See `cle.Loader.dynamic_load` and `angr.procedures.win32.dynamic_loading` for details.
- The knowledge base has been refactored into a series of plugins similar to SimState (credit @danse-macabre)
- The testcase-based function identifier we wrote for CGC has been integrated into angr as the Identifier analysis
- Improved support for writing custom VEX lifters

### 9.5.15 angr 6.7.6.9

- angr: A static data-flow analysis framework has been introduced, and implemented as part of the `ForwardAnalysis` class. Additionally, a few exemplary data-flow analyses, like `VariableRecovery` and `VariableRecoveryFast`, have been implemented in angr.
- angr: We introduced the notion of *variable* to the angr world. Now a VariableManager is available in the knowledge base. Variable information can be recovered by running a variable recovery analysis. Currently the variable information recovered for each function is still pretty coarse. More updates to it will arrive soon.
- angr: Fix a bug in the topological sorting in `CFGUtils`, which resulted in suboptimal graph node ordering after sorting.
- SimuVEX: `LAZY_SOLVES` is no longer enabled by default during symbolic execution. It's still there if it's wanted, but it just caused confusion when on by default.
- SimuVEX: Thanks to @ekilmer, a few new libc SimProcedures are added.
- SimuVEX: The default memory model has been refactored for expandability. Custom pages can now be created (derive the simuvex.storage.ListPage class) and used instead of the default page classes to implement custom memory behavior for specific pages. The user-friendly API for this is pending the next release.
- angr-management: Implemented our own graph layout and edge routing algorithm. We do not rely on grandalf anymore.
- angr-management: Added support for displaying variable information for operands.
- angr-management: Added support for highlighting dependent operands when an operand is highlighted.

### 9.5.16 angr 6.7.3.26

Building off of the engine changes from the last release, we have begun to extend angr to other architectures. AVR and MSP430 are in progress. In the meantime, subwire has created a reference implementation of BrainFuck support in angr, done two different ways! Check out angr-platforms for more info!

- We have rebased our fork of VEX on the latest master branch from Valgrind (as of 2 months ago, at least...). We have also submitted our patches to VEX to upstream, so we should be able to stop maintaining a fork pretty soon.
- The way we interact with VEX has changed substantially, and should speed things up a bit.
- Loading sets of binaries with many import symbols has been sped up

- Many, many improvements to angr-management, including the switch away from enaml to using pyside directly.

### 9.5.17 angr 6.7.1.13

For the last month, we have been working on a major refactor of the angr to change the way that angr reasons about the code that it analyzes. Until now, angr has been bound to the VEX intermediate representation to lift native code, supporting a wide range of architectures but not being very expandable past them. This release represents the ground work for what we call translation and execution engines. These engines are independent backends, pluggable into the angr framework, that will allow angr to reason about a wide range of targets. For now, we have restructured the existing VEX and Unicorn Engine support into this engine paradigm, but as we discuss in our blog post, the plan is to create engines to enable angr's reasoning of Java bytecode and source code, and to augment angr's environment support through the use of external dynamic sandboxes.

For now, these changes are mostly internal. We have attempted to maintain compatibility for end-users, but those building systems atop angr will have to adapt to the modern codebase. The following are the major changes:

- simuvex: we have introduced SimEngine. SimEngine is a base class for abstractions over native code. For example, angr's VEX-specific functionality is now concentrated in SimEngineVEX, and new engines (such as SimEngineLLVM) can be implemented (even outside of simuvex itself) to support the analysis of new types of code.
- simuvex: as part of the engines refactor, the SimRun class has been eliminated. Instead of different subclasses of SimRun that would be instantiated from an input state, engines each have a `process` function that, from an input state, produces a SimSuccessors instance containing lists of different successor states (normal, unsat, unconstrained, etc) and any engine-specific artifacts (such as the VEX statements. Take a look at `successors.artifacts`).
- simuvex: `state.mem[x:] = y` now *requires* a type for storage (for example `state.mem[x:].dword = y`).
- simuvex: the way of calling inline SimProcedures has been changed. Now you have to create a SimProcedure, and then call `execute()` on it and pass in a program state as well as the arguments.
- simuvex: accessing registers through `SimRegNameView` (like `state.regs.eax`) always triggers SimInspect breakpoints and creates new actions. Now you can access a register by prefixing its name with an underscore (e.g. `state.regs._eax` or `state._ip`) to avoid triggering breakpoints or creating actions.
- angr: the way hooks work has slightly changed, though is backwards-compatible. The new angr.Hook class acts as a wrapper for hooks (SimProcedures and functions), keeping things cleaner in the `project._sim_procedures` dict.
- angr: we have deprecated the keyword argument `max_size` and changed it to to `size` in the `angr.Block` constructor (i.e., the argument to `project.factory.block` and more upstream methods (`path.step`, `path_group.step`, etc).
- angr: we have deprecated `project.factory.sim_run` and changed it to to `project.factory.successors`, and it now generates a `SimSuccessors` object.
- angr: `project.factory.sim_block` has been deprecated and replaced with `project.factory.successors(default_engine=True)`.
- angr: angr syscalls are no longer hooks. Instead, the syscall table is now in `project._simos.syscall_table`. This will be made "public" after a usability refactor. If you were using `project.is_hooked(addr)` to see if an address has a related SimProcedure, now you probably want to check if there is a related syscall as well (using `project._simos.syscall_table.get_by_addr(addr) is not None`).
- pyvex: to support custom lifters to VEX, pyvex has introduced the concept of backend lifters. Lifters can be written in pure Python to produce VEX IR, allowing for extendability of angr's VEX-based analyses to other hardware architectures.

As usual, there are many other improvements and minor bugfixes.

- claripy: support `unsat_core()` to get the core of unsatness of constraints. It is in fact a thin wrapper of the `unsat_core()` function provided by Z3. Also a new state option `CONSTRAINT_TRACKING_IN_SOLVER` is added to SimuVEX. That state option must be enabled if you want to use `unsat_core()` on any state.
- simuvex: `SimMemory.load()` and `SimMemory.store()` now takes a new parameter `disable_actions`. Setting it to True will prevent any SimAction creation.
- angr: CFGFast has a better support for ARM binaries, especially for code in THUMB mode.
- angr: thanks to an improvement in SimuVEX, CFGAccurate now uses slightly less memory than before.
- angr: `len()` on path `trace` or `addr_trace` is made much faster.
- angr: Fix a crash during CFG generation or symbolic execution on platforms/architectures with no syscall defined.
- angr: as part of the refactor, `BackwardSlicing` is temporarily disabled. It will be re-enabled once all DDG-related refactor are merged to master.

Additionally, packaging and build-system improvements coordinated between the angr and Unicorn Engine projects have allowed angr's Unicorn support to be built on Windows. Because of this, `unicorn` is now a dependency for `simuvex`.

Looking forward, angr is poised to become a program analysis engine for binaries *and more*!

### 9.5.18 angr 5.6.12.3

It has been over a month since the last release 5.6.10.12. Again, we've made some significant changes and improvements on the code base.

- angr: Labels are now stored in KnowledgeBase.
- angr: Add a new analysis: `Disassembly`. The new Disassembly analysis provides an easy-to-use interface to render assembly of functions.
- angr: Fix the issue that `ForwardAnalysis` may prematurely terminate while there are still un-processed jobs.
- angr: Many small improvements and bug fixes on `CFGFast`.
- angr: Many small improvements and bug fixes on `VFG`. Bring back widening support. Fix the issue that `VFG` may not terminate under certain cases. Implement a new graph traversal algorithm to have an optimal traversal order. Allow state merging at non-merge-points, which allows faster convergence.
- angr-management: Display a progress during initial CFG recovery.
- angr-management: Display a "Load binary" window upon binary loading. Some analysis options can be adjusted there.
- angr-management: Disassembly view: Edge routing on the graph is improved.
- angr-management: Disassembly view: Support starting a new symbolic execution task from an arbitrary address in the program.
- angr-management: Disassembly view: Support renaming of function names and labels.
- angr-management: Disassembly view: Support "Jump to address".
- angr-management: Disassembly view: Display resolved and unresolved jump targets. All jump targets are double-clickable.
- SimuVEX: Move region mapping from `SimAbstractMemory` to `SimMemory`. This will allow an easier conversion between `SimAbstractMemory` and `SimSymbolicMemory`, which is to say, conversion between symbolic states and static states is now possible.

- SimuVEX & claripy: Provide support for `unsat_core` in Z3. It returns a set of constraints that led to unsatness of the constraint set on the current state.
- archinfo: Add a new Boolean variable `branch_delay_slot` for each architecture. It is set to True on MIPS32.

### 9.5.19 angr 5.6.8.22

Major point release! An incredible number of things have changed in the month run-up to the Cyber Grand Challenge.

- Integration with Unicorn Engine supported for concrete execution. A new SimRun type, SimUnicorn, may step through many basic blocks at once, so long as there is no operation on symbolic data. Please use our fork of unicorn engine, which has many patches applied. All these patches are pending merge into upstream.
- Lots of improvements and bug fixes to CFGFast. Rumors are angr's CFG was only "optimized" for x86-64 binaries (which is really because most of our test cases are compiled as 64-bit ELFs). Now it is also "optimized" for x86 binaries :) (editor's note: angr is built with cross-architecture analysis in mind. CFG construction is pretty much the only component which has architecture-specific behavior.)
- Lots of improvements to the VFG analysis, including speed and accuracy. However, there is still a lot to be done.
- Lots of speed optimizations in general - CFGFast should be 3-6x faster under CPython with much less memory usage.
- Now data dependence graph gives you a real dependence graph between variable definitions. Try `data_graph` and `simplified_data_graph` on a DDG object!
- New state option `simuvex.o.STRICT_PAGE_ACCESS` will cause a `SimSegfaultError` to be raised whenever the guest reads/writes/executes memory that is either unmapped or doesn't have the appropriate permissions.
- Merging of paths (as opposed to states) is performed in a much smarter way.
- The behavior of the `support_selfmodifying_code` project option is changed: Before, this would allow the state to be used as a fallback source of instruction bytes when no backer from CLE is available. Now, this option makes instruction lifting use the state as the source of bytes always. When the option is disabled and execution jumps outside the normal binary, the state will be used automatically.
- *Actually* support self-modifying code - if a basic block of code modifies itself, the block will be re-lifted before the next instruction starts.
- Syscalls are handled differently now - Before you would see a SimRun for a syscall helper, now you'll just see a SimProcedure for the given syscall. Additionally, each syscall has its own address in a "syscalls segment", and syscalls are treated as jumps to this segment. This simplifies a lot of things analysis-wise.
- CFGAccurate accepts a `base_graph` keyword to its constructor, e.g. `CFGFast().graph`, or even `.graph` of a function, to use as a base for analysis.
- New fast memory model for cases where symbolic-addressed reads and writes are unlikely.
- Conflicts between the `find` and `avoid` parameters to the Explorer otiegnqwvk are resolved correctly. (credit clslgrnc)
- New analysis `StaticHooker` which hooks library functions in unstripped statically linked binaries.
- `Lifter` can be used without creating an angr Project. You must manually specify the architecture and bytestring in calls to `.lift()` and `.fresh_block()`. If you like, you can also specify the architecture as a parameter to the constructor and omit it from the lifting calls.
- Add two new analyses developed for the CGC (mostly as examples of doing static analysis with angr): Reassembler and BinaryOptimizer.

### 9.5.20 angr 4.6.6.28

In general, there have been enormous amounts of speed improvements in this release. Depending on the workload, angr should run about twice as fast. Aside from this, there have also been many submodule-specific changes:

#### angr

Quite a few changes and improvements are made to `CFGFast` and `CFGAccurate` in order to have better and faster CFG recovery. The two biggest changes in `CFGFast` are jump table resolution and data references collection, respectively. Now `CFGFast` resolves indirect jumps by default. You may get a list of indirect jumps recovered in `CFGFast` by accessing the `indirect_jumps` attribute. For many cases, it resolves the jump table accurately. Data references collection is still in alpha mode. To test data references collection, just pass `collect_data_references=True` when creating a fast CFG, and access the `memory_data` attribute after the CFG is constructed.

CFG recovery on ARM binaries is also improved.

A new paradigm called an "otiegnqwvk", or an "exploration technique", allows the packaging of special logic related to path group stepping.

#### SimuVEX

Reads/writes to the x87 fpu registers now work correctly - there is special logic that rotates a pointer into part of the register file to simulate the x87 stack.

With the recent changes to Claripy, we have configured SimuVEX to use the composite solver by default. This should be transparent, but should be considered if strange issues (or differences in behavior) arise during symbolic execution.

#### Claripy

Fixed a bug in claripy where `div__` was not always doing unsigned division, and added new methods `SDiv` and `SMod` for signed division and signed remainder, respectively.

Claripy frontends have been completely rewritten into a mixin-centric solver design. Basic frontend functionality (i.e., calling into the solver or dealing with backends) is handled by frontends (in `claripy.frontends`), and additional functionality (such as caching, deciding when to simplify, etc) is handled by frontend mixins (in `claripy.frontend_mixins`). This makes it considerably easier to customize solvers to your specific needE. For examples, look at `claripy/solver.py`.

Alongside the solver rewrite, the composite solver (which splits constraints into independent constraint sets for faster solving) has been immensely improved and is now functional and fast.

### 9.5.21 angr 4.6.6.4

Syscalls are no longer handled by `simuvex.procedures.syscalls.handler`. Instead, syscalls are now handled by `angr.SimOS.handle_syscall()`. Previously, the address of a syscall SimProcedure is the address right after the syscall instruction (e.g. `int 80h`), which collides with the real basic block starting at that address, and is very confusing. Now each syscall SimProcedure has its own address, just as a normal SimProcedure. To support this, there is another region mapped for the syscall addresses, `Project._syscall_obj`.

Some refactoring and bug fixes in `CFGFast`.

Claripy has been given the ability to handle *annotations* on ASTs. An annotation can be used to customize the behavior of some backends without impacting others. For more information, check the docstrings of `claripy.Annotation` and `claripy.Backend.apply_annotation`.

### 9.5.22 angr 4.6.5.25

New state constructor - `call_state`. Comes with a refactor to `SimCC`, a refactor to `callable`, and the removal of `PathGroup.call`. All these changes are thoroughly documented, in `angr/docs/advanced-topics/structured_data.md`

Refactor of `SimType` to make it easier to use types - they can be instantiated without a SimState and one can be added later. Comes with some usability improvements to SimMemView. Also, there's a better wrapper around PyCParser for generating SimType instances from c declarations and definitions. Again, thoroughly documented, still in the structured data doc.

`CFG` is now an alias to `CFGFast` instead of `CFGAccurate`. In general, `CFGFast` should work under most cases, and it's way faster than `CFGAccurate`. We believe such a change is necessary, and will make angr more approachable to new users. You will have to change your code from `CFG` to `CFGAccurate` if you are relying on specific functionalities that only exist in `CFGAccurate`, for example, context-sensitivity and state-preserving. An exception will be raised by angr if any parameter passed to `CFG` is only supported by `CFGAccurate`. For more detailed explanation, please take a look at the documentation of `angr.analyses.CFG`.

### 9.5.23 angr 4.6.3.28

PyVEX has a structural overhaul. The `IRExpr`, `IRStmt`, and `IRConst` modules no longer exist as submodules, and those module names are deprecated. Use `pyvex.expr`, `pyvex.stmt`, and `pyvex.const` if you need to access the members of those modules.

The names of the first three parameters to `pyvex.IRSB` (the required ones) have been changed. If you were passing the positional args to IRSB as keyword args, consider switching to positional args. The order is `data`, `mem_addr`, `arch`.

The optional parameter `sargc` to the `entry_state` and `full_init_state` constructors has been removed and replaced with an `argc` parameter. `sargc` predates being able to have claripy ASTs independent from a solver. The new system is to pass in the exact value, ast or integer, that you'd like to have as the guest program's arg count.

CLE and angr can now accept file-like streams, that is, objects that support `stream.read()` and `stream.seek()` can be passed in wherever a filepath is expected.

Documentation is much more complete, especially for PyVEX and angr's symbolic execution control components.

### 9.5.24 angr 4.6.3.15

There have been several improvements to claripy that should be transparent to users:

- There's been a refactoring of the VSA StridedInterval classes to fix cases where operations were not sound. Precision might suffer as a result, however.
- Some general speed improvements.
- We've introduced a new backend into claripy: the ReplacementBackend. This frontend generates replacement sets from constraints added to it, and uses these replacement sets to increase the precision of VSA. Additionally, we have introduced the HybridBackend, which combines this functionality with a constraint solver, allowing for memory index resolution using VSA.

angr itself has undergone some improvements, with API changes as a result:

- We are moving toward a new way to store information that angr has recovered about a program: the knowledge base. When an analysis recovers some truth about a program (i.e., "there's a basic block at 0x400400", or "the block at 0x400400 has a jump to 0x400500"), it gets stored in a knowledge-base. Analysis that used to store data (currently, the CFG) now store them in a knowledge base and can *share* the global knowledge base of the project, now accessible via `project.kb`. Over time, this knowledge base will be expanded in the course of any analysis or symbolic execution, so angr is constantly learning more information about the program it is analyzing.
- A forward data-flow analysis framework (called ForwardAnalysis) has been introduced, and the CFG was rewritten on top of it. The framework is still in alpha stage - expect more changes to be made. Documentation and

more details will arrive shortly. The goal is to refactor other data-flow analysis, like CFGFast, VFG, DDG, etc. to use ForwardAnalysis.

- We refactored the CFG to a) improve code readability, and b) eliminate some bad designs that linger due to historical reasons.

### 9.5.25 angr 4.5.12.?

Claripy has a new manager for backends, allowing external backends (i.e., those implemented by other modules) to be used. The result is that `claripy.backend_concrete` is now `claripy.backends.concrete`, `claripy.backend_vsa` is now `claripy.backends.vsa`, and so on.

### 9.5.26 angr 4.5.12.12

Improved the ability to recover from failures in instruction decoding. You can now hook specific addresses at which VEX fails to decode with `project.hook`, even if those addresses are not the beginning of a basic block.

### 9.5.27 angr 4.5.11.23

This is a pretty beefy release, with over half of claripy having been rewritten and major changes to other analyses. Internally, Claripy has been unified – the VSA mode and symbolic mode now work on the same structures instead of requiring structures to be created differently. This opens the door for awesome capabilities in the future, but could also result in unexpected behavior if we failed to account for something.

Claripy has had some major interface changes:

- claripy.BV has been renamed to claripy.BVS (bit-vector symbol). It can now create bitvectors out of strings (i.e., claripy.BVS(0x41, 8) and claripy.BVS("A") are identical).
- state.BV and state.BVV are deprecated. Please use state.se.BVS and state.se.BVV.
- BV.model is deprecated. If you're using it, you're doing something wrong, anyways. If you really need a specific model, convert it with the appropriate backend (i.e., claripy.backend_concrete.convert(bv)).

There have also been some changes to analyses:

- Interface: CFG argument `keep_input_state` has been renamed to `keep_state`. With this option enabled, both input and final states are kept.
- Interface: Two arguments `cfg_node` and `stmt_id` of `BackwardSlicing` have been deprecated. Instead, `BackwardSlicing` takes a single argument, `targets`. This means that we now support slicing from multiple sources.
- Performance: The speed of CFG recovery has been slightly improved. There is a noticeable speed improvement on MIPS binaries.
- Several bugs have been fixed in DDG, and some sanity checks were added to make it more usable.

And some general changes to angr itself:

- StringSpec is deprecated! You can now pass claripy bitvectors directly as arguments.

## 9.6 Migrating to angr 9.1

angr 9.1 is here!

### 9.6.1 Calling Conventions and Prototypes

The main change motivating angr 9.1 is this large refactor of SimCC. Here are the breaking changes:

#### SimCCs can no longer be customized

If you were using the `sp_delta`, `args`, or `ret_val` parameters to SimCC, you should use the new class `SimCCUsercall`, which lets (requires) you to be explicit about the locations of each argument.

#### Passing SimTypes is now mandatory

Every method call on SimCC which interacts with typed data now requires a SimType to be passed in. Previously, the use of `is_fp` and `size` was optional, but now these parameters will no longer be accepted and a `SimType` will be required.

This has some fairly non-intuitive consequences - in order to accommodate more esoteric calling conventions (think: passing large structs by value via an "invisible reference") you have to specify a function's return type before you can extract any of its arguments.

Additionally, some non-cc interfaces, such as `call_state` and `callable` and `SimProcedure.call()`, now *require* a prototype to be passed to them. You'd be surprised how many bugs we found in our own code from enforcing this requirement!

#### PointerWrapper has a new parameter

Imagine you're passing something into a function which has a parameter of type `char*`. Is this a pointer to a single char or a pointer to an array of chars? The answer changes how we typecheck the values you pass in. If you're passing a PointerWrapper wrapping a large value which should be treated as an array of chars, you should construct your pointerwrapper as `PointerWrapper(foo, buffer=True)`. The buffer argument to PointerWrapper now instructs SimCC to treat the data to be serialized as an array of the child type instead of as a scalar.

#### `func_ty -> prototype`

Every usage of the name func_ty has been replaced with the name prototype. This was done for consistency between the static analysis code and the dynamic FFI.

## 9.7 Migrating to angr 8

angr has moved from Python 2 to Python 3! We took this opportunity of a major version bump to make a few breaking API changes that improve quality-of-life.

### 9.7.1 What do I need to know for migrating my scripts to Python 3?

To begin, just the standard py3k changes, the relevant parts of which we'll rehash here as a reference guide:

- Strings and bytestrings
  - Strings are now unicode by default, a new `bytes` type holds bytestrings
  - Bytestring literals can be constructed with the b prefix, like `b'ABCD'`
  - Conversion between strings and bytestrings happens with `.encode()` and `.decode()`, which use utf-8 as a default. The `latin-1` codec will map byte values to their equivalent unicode codepoints
  - The `ord()` and `chr()` functions operate on strings, not bytestrings
  - Enumerating over or indexing into bytestrings produces an unsigned 8 bit integer, not a 1-byte bytestring
  - Bytestrings have all the string manipulation functions present on strings, including `join`, `upper/lower`, `translate`, etc

  - `hex` and `base64` are no longer string encoding codecs. For hex, use `bytes.fromhex()` and `bytes.hex()`. For base64 use the `base64` module.

- Builtin functions
  - `print` and `exec` are now builtin functions instead of statements
  - Many builtin functions previously returning lists now return iterators, such as `map`, `filter`, and `zip`. `reduce` is no longer a builtin; you have to import it from `functools`.

- Numbers
  - The `/` operator is explicitly floating-point division, the `//` operator is expliclty integer division. The magic functions for overriding these ops are `truediv__` and `floordiv__`
  - The int and long types have been merged, there is only int now

- Dictionary objects have had their `.iterkeys`, `.itervalues`, and `.iteritems` methods removed, and then non-iter versions have been made to return efficient iterators

- Comparisons between objects of very different types (such as between strings and ints) will raise an exception

In terms of how this has affected angr, any string that represents data from the emulated program will be a bytestring. This means that where you previously said `state.solver.eval(x, cast_to=str)` you should now say `cast_to=bytes`. When creating concrete bitvectors from strings (including implicitly by just making a comparison against a string) these should be bytestrings. If they are not they will be utf-8 converted and a warning will be printed. Symbol names should be unicode strings.

For division, however, ASTs are strongly typed so they will treat both division operators as the kind of division that makes sense for their type.

### 9.7.2 Clemory API changes

The memory object in CLE (project.loader.memory, not state.memory) has had a few breaking API changes since the bytes type is much nicer to work with than the py2 string for this specific case, and the old API was an inconsistent mess.

| Before | After |
|---|---|
| `memory.read_bytes(addr, n) -> list[str]` | `memory.load(addr, n) -> bytes` |
| `memory.write_bytes(addr, list[str])` | `memory.store(addr, bytes)` |
| `memory.get_byte(addr) -> str` | `memory[addr] -> int` |
| `memory.read_addr_at(addr) -> int` | `memory.unpack_word(addr) -> int` |
| `memory.write_addr_at(addr, value) -> int` | `memory.pack_word(addr, value)` |
| `memory.stride_repr -> list[(start, end, str)]` | `memory.backers() -> iter[(start, bytearray)]` |

Additionally, `pack_word` and `unpack_word` now take optional `size`, `endness`, and `signed` parameters. We have also added `memory.pack(addr, fmt, *data)` and `memory.unpack(addr, fmt)`, which take format strings for use with the `struct` module.

If you were using the `cbackers` or `read_bytes_c` functions, the conversion is a little more complicated - we were able to remove the split notion of "backers" and "updates" and replaced all backers with bytearrays that we mutate, so we can work directly with the backer objects. The `backers()` function iterates through all bottom-level backer objects and their start addresses. You can provide an optional address to the function, and it will skip over all backers that end before that address.

Here is some sample code for producing a C-pointer to a given address:

```
import cffi, cle
ffi = cffi.FFI()
ld = cle.Loader('/bin/true')

addr = ld.main_object.entry
try:
    backer_start, backer = next(ld.memory.backers(addr))
except StopIteration:
    raise Exception("not mapped")

if backer_start > addr:
    raise Exception("not mapped")

cbacker = ffi.from_buffer(backer)
addr_pointer = cbacker + (addr - backer_start)
```

You should not have to use this if you aren't passing the data to a native library - the normal load methods should now be more than fast enough for intensive use.

### 9.7.3 CLE symbols changes

Previously, your mechanisms for looking up symbols by their address were `loader.find_symbol()` and `object.symbols_by_addr`, where there was clearly some overlap. However, `symbols_by_addr` stayed because it was the only way to enumerate symbols in an object. This has changed! `symbols_by_addr` is deprecated and here is now `object.symbols`, a sorted list of Symbol objects, to enumerate symbols in a binary.

Additionally, you can now enumerate all symbols in the entire project with `loader.symbols`. This change has also enabled us to add a `fuzzy` parameter to `find_symbol` (returns the first symbol before the given address) and make the output of `loader.describe_addr` much nicer (shows offset from closest symbol).

### 9.7.4 Deprecations and name changes

- All parameters in cle that started with `custom_` - so, `custom_base_addr`, `custom_entry_point`, `custom_offset`, `custom_arch`, and `custom_ld_path` - have had the `custom_` removed from the beginning of their names.
- All the functions that were deprecated more than a year ago (at or before the angr 7 release) have been removed.
- `state.se` has been deprecated. You should have been using `state.solver` for the past few years.
- Support for immutable simulation managers has been removed. So far as we're aware, nobody was actually using this, and it was making debugging a pain.

## 9.8 Migrating to angr 7

The release of angr 7 introduces several departures from long-standing angr-isms. While the community has created a compatibility layer to give external code written for angr 6 a good chance of working on angr 7, the best thing to do is to port it to the new version. This document serves as a guide for this.

### 9.8.1 SimuVEX is gone

angr versions up through angr 6 split the program analysis into two modules: `simuvex`, which was responsible for analyzing the effects of a single piece of code (whether a basic block or a SimProcedure) on a program state, and `angr`, which aggregated analyses of these basic blocks into program-level analysis such as control-flow recovery, symbolic execution, and so forth. In theory, this would encourage for the encapsulation of block-level analyses, and allow other

program analysis frameworks to build upon `simuvex` for their needs. In practice, no one (to our knowledge) used `simuvex` without `angr`, and the separation introduced frustrating limitations (such as not being able to reference the history of a state from a SimInspect breakpoint) and duplication of code (such as the need to synchronize data from `state.scratch` into `path.history`).

Realizing that SimuVEX wasn't a usable independent package, we brainstormed about merging it into angr and further noticed that this would allow us to address the frustrations resulting from their separation.

All of the SimuVEX concepts (SimStates, SimProcedures, calling conventions, types, etc) have been migrated into angr. The migration guide for common classes is bellow:

| Before | After |
|---|---|
| simuvex.SimState | angr.SimState |
| simuvex.SimProcedure | angr.SimProcedure |
| simuvex.SimEngine | angr.SimEngine |
| simuvex.SimCC | angr.SimCC |

And for common modules:

| Before | After |
|---|---|
| simuvex.s_cc | angr.calling_conventions |
| simuvex.s_state | angr.sim_state |
| simuvex.s_procedure | angr.sim_procedure |
| simuvex.plugins | angr.state_plugins |
| simuvex.engines | angr.engines |
| simuvex.concretization_strategies | angr.concretization_strategies |

Additionally, `simuvex.SimProcedures` has been renamed to `angr.SIM_PROCEDURES`, since it is a global variable and not a class. There have been some other changes to its semantics, see the section on SimProcedures for details.

### 9.8.2 Removal of angr.Path

In angr, a Path object maintained references to a SimState and its history. The fact that the history was separated from the state caused a lot of headaches when trying to analyze states inside a breakpoint, and caused overhead in synchronizing data from the state to its history.

In the new model, a state's history is maintained in a SimState plugin: `state.history`. Since the path would now simply point to the state, we got rid of it. The mapping of concepts is roughly as follows:

| Before | After |
|---|---|
| path | state |
| path.state | state |
| path.history | state.history |
| path.callstack | state.callstack |
| path.trace | state.history.descriptions |
| path.addr_trace | state.history.bbl_addrs |
| path.jumpkinds | state.history.jumpkinds |
| path.guards | state.history.jump_guards |
| path.targets | state.history.jump_targets |
| path.actions | state.history.actions |
| path.events | state.history.events |
| path.recent_actions | state.history.recent_actions |
| path.reachable | state.history.reachable() |

An important behavior change about `path.actions` and `path.recent_actions` - actions are no longer tracked by default. If you would like them to be tracked again, please add `angr.options.refs` to your state.

#### Path Group -> Simulation Manager

Since there are no paths, there cannot be a path group. Instead, we have a Simulation Manager now (we recommend using the abbreviation "simgr" in places you were previously using "pg"), which is exactly the same as a path group except it holds states instead of paths. You can make one with `project.factory.simulation_manager(...)`.

#### Errored Paths

Before, error resilience was handled at the path level, where stepping a path that caused an error would return a subclass of Path called ErroredPath, and these paths would be put in the `errored` stash of a path group. Now, error resilience is handled at the simulation manager level, and any state that throws an error during stepping will be wrapped in an ErrorRecord object, which is *not* a subclass of SimState, and put into the `errored` list attribute of the simulation manager, which is *not* a stash.

An ErrorRecord object has attributes for `.state` (the initial state that caused the error), `.error` (the error that was thrown), and `.traceback` (the traceback from the error). To debug these errors you can call `.debug()`.

These changes are because we were uncomfortable making a subclass of SimState, and the ErrorRecord class then has sufficiently different semantics from a normal state that it cannot be placed in a stash.

### 9.8.3 Changes to SimProcedures

The most noticeable difference from the old version to the new version is that the catalog of built-in simprocedures are no longer organized strictly according to which library they live in. Now, they are organized according to which *standards* they conform to, which helps with re-using procedures between different libraries. For instance, the old `SimProcedures['libc.so.6']` has been split up between `SIM_PROCEDURES['libc']`, `SIM_PROCEDURES['posix']`, and `SIM_PROCEDURES['glibc']`, depending on what specifications each function conforms to. This allows us to reuse the `libc` catalog in `msvcrt.dll` and the MUSL libc, for example.

In order to group SimProcedures together by libraries, we have introduced a new abstraction called the SimLibrary, the definitions for which are stored in `angr.procedures.definitions`. Each SimLibrary object stores information about a single shared library, and can contain SimProcedure implementations, calling convention information, and type information. SimLibraries are scraped from the filesystem at import time, just like SimProcedures, and placed into `angr.SIM_LIBRARIES`.

Syscalls are now categorized through a subclass of SimLibrary called SimSyscallLibrary. The API for managing syscalls through SimOS has been changed - check the API docs for the SimUserspace class.

One important implication of this change is that if you previously used a trick where you changed one of the SimProcedures present in the `SimProcedures` dict in order to change which SimProcedures would be used to hook over library functions by default, this will no longer work. Instead of `SimProcedures[lib][func_name] = proc`, you now need to say `SIM_LIBRARIES[lib].add(func_name, proc)`. But really you should just be using `hook_symbol` anyway.

### 9.8.4 Changes to hooking

The `Hook` class is gone. Instead, we now can hook with individual instances of SimProcedure objects, as opposed to just the classes. A shallow copy of the SimProcedure will be made at runtime to preserve thread safety.

So, previously, where you would have done `project.hook(addr, Hook(proc, ...))` or `project.hook(addr, proc)`, you can now do `project.hook(addr, proc(...))`. In order to use simple functions as hooks, you can either say `project.hook(addr, func)` or decorate the declaration of your function with `@project.hook(addr)`.

Having simprocedures as instances and letting them have access to the project cleans up a lot of other hacks that were present in the codebase, mostly related to the `self.call(...)` SimProcedure continuation system. It is no longer required to set `IS_FUNCTION = True` if you intend to use `self.call()` while writing a SimProcedure, and each call-return target you use will have a unique address associated with it. These addresses will be allocated lazily, which does have the side effect of making address allocation nondeterministic, sometimes based on dictionary-iteration order.

### 9.8.5 Changes to loading

The `hook_symbol` method will no longer attempt to redo relocations for the given symbol, instead just hooking directly over the address of the symbol in whatever library it comes from. This speeds up loading substantially and ensures more consistent behavior for when mixing and matching native library code and SimProcedure summaries.

The angr externs object has been moved into CLE, which will ALWAYS make sure that every dependency is resolved to something, never left unrelocated. Similarly, CLE provides the "kernel object" used to provide addresses for syscalls now.

| Before | After |
|---|---|
| `project._extern_obj` | `loader.extern_object` |
| `project._syscall_obj` | `loader.kernel_object` |

Several properties and methods have been renamed in CLE in order to maintain a more consistent and explicit API. The most common changes are listed below:

| Before | After |
|---|---|
| `loader.whats_at()` | `loader.describe_addr` |
| `loader.addr_belongs_to_object()` | `loader.find_object_containing()` |
| `loader.find_symbol_name()` | `loader.find_symbol().name` |
| whatever the hell you were doing before to look up a symbol | `loader.find_symbol(name or addr)` |
| `loader.find_module_name()` | `loader.find_object_containing().provides` |
| `loader.find_symbol_got_entry()` | `loader.find_relevant_relocations()` |
| `loader.main_bin` | `loader.main_object` |
| `anything.get_min_addr()` | `anything.min_addr` |
| `symbol.addr` | `symbol.linked_addr` |

### 9.8.6 Changes to the solver interface

We cleaned up the menagerie of functions present on `state.solver` (if you're still referring to it as `state.se` you should stop) and simplified it into a cleaner interface:

- `solver.eval(expression)` will give you one possible solution to the given expression.
- `solver.eval_one(expression)` will give you the solution to the given expression, or throw an error if more than one solution is possible.
- `solver.eval_upto(expression, n)` will give you up to n solutions to the given expression, returning fewer than n if fewer than n are possible.
- `solver.eval_atleast(expression, n)` will give you n solutions to the given expression, throwing an error if fewer than n are possible.
- `solver.eval_exact(expression, n)` will give you n solutions to the given expression, throwing an error if fewer or more than are possible.
- `solver.min(expression)` will give you the minimum possible solution to the given expression.
- `solver.max(expression)` will give you the maximum possible solution to the given expression.

Additionally, all of these methods can take the following keyword arguments:

- `extra_constraints` can be passed as a tuple of constraints. These constraints will be taken into account for this evaluation, but will not be added to the state.
- `cast_to` can be passed a data type to cast the result to. Currently, this can only be `str`, which will cause the method to return the byte representation of the underlying data. For example, `state.solver.eval(state.solver.BVV(0x41424344, 32, cast_to=str)` will return `"ABCD"`.

*angr*

CHAPTER

# TEN

# API REFERENCE

**class** angr.**BP**

Bases: object

A breakpoint.

**__init__**(*when=When.BEFORE*, *enabled=True*, *condition=None*, *action=<function BP_IPDB>*, ***kwargs*)

**Parameters**

- **when** (When)
- **enabled** (*bool*)
- **condition** (*Callable[[SimState], bool] | None*)
- **action** (Action)
- **kwargs** (*dict[str, Any]*)

**check**(*state*, *when*)

Checks state *state* to see if the breakpoint should fire.

**Parameters**

- **state** (*SimState*) – The state.
- **when** (*When*) – Whether the check is happening before or after the event.

**Return type**
bool

**Returns**
A boolean representing whether the checkpoint should fire.

**fire**(*state*)

Trigger the breakpoint.

**Parameters**
**state** (*SimState*) – The state.

angr.**BP_IPDB**(*state*)

**Return type**
None

**Parameters**
**state** (SimState)

angr.**BP_IPYTHON**(*state*)

**Return type**
None

**Parameters**
**state** (SimState)

**class** angr.**Analysis**

Bases: object

This class represents an analysis on the program.

**Variables**

- **project** (*Project*) – The project for this analysis.
- **kb** (KnowledgeBase) – The knowledgebase object.
- **_progress_callback** (Callable | None) – A callback function for receiving the progress of this analysis. It only takes one argument, which is a float number from 0.0 to 100.0 indicating the current progress.
- **_show_progressbar** (*bool*) – If a progressbar should be shown during the analysis. It's independent from _progress_callback.
- **_progressbar** (*progress.Progress*) – The progress bar object.

**project:** *Project*

**kb:** *KnowledgeBase*

**errors:** list[*AnalysisLogEntry*] = []

**named_errors:** defaultdict[str, list[*AnalysisLogEntry*]] = {}

**log:** list

**property ram_usage:** float

Return the current RAM usage of the Python process, in bytes. The value is updated at most once per second.

**exception** angr.**AngrAIError**

**class** angr.**Blade**

Bases: object

Blade is a light-weight program slicer that works with networkx DiGraph containing CFGNodes. It is meant to be used in angr for small or on-the-fly analyses.

**__init__**(*graph*, *dst_run*, *dst_stmt_idx*, *direction='backward'*, *project=None*, *cfg=None*, *ignore_sp=False*, *ignore_bp=False*, *ignored_regs=None*, *max_level=3*, *base_state=None*, *stop_at_calls=False*, *cross_insn_opt=False*, *max_predecessors=10*, *include_imarks=True*, *control_dependence=True*, *block_cache=None*)

**Parameters**

- **graph** (DiGraph) – A graph representing the control flow graph. Note that it does not take angr.analyses.CFGEmulated or angr.analyses.CFGFast.
- **dst_run** (int) – An address specifying the target SimRun.
- **dst_stmt_idx** (int) – The target statement index. -1 means executing until the last statement.
- **direction** (str) – 'backward' or 'forward' slicing. Forward slicing is not yet supported.
- **project** (*angr.Project*) – The project instance.
- **cfg** (*angr.analyses.CFGBase*) – the CFG instance. It will be made mandatory later.
- **ignore_sp** (bool) – Whether the stack pointer should be ignored in dependency tracking. Any dependency from/to stack pointers will be ignored if this options is True.
- **ignore_bp** (bool) – Whether the base pointer should be ignored or not.
- **max_level** (int) – The maximum number of blocks that we trace back for.
- **stop_at_calls** (bool) – Limit slicing within a single function. Do not proceed when encounters a call edge.
- **include_imarks** (bool) – Should IMarks (instruction boundaries) be included in the slice.
- **control_dependence** (bool) – Whether to consider control dependencies. If True, the temps controlling conditional exits will be added to the tainting set.
- **block_cache** (dict[int, *Block*] | None) – Lifted blocks keyed by address, shared with the caller so that slices of the same region (e.g., at growing depths) lift each block once. The caller must only share it between slices lifted with the same parameters.
- **max_predecessors** (*int*)

**Returns**

None

**property slice**

**get_block**(*addr*)

The block at addr, lifted with this slice's parameters (cached).

**Return type**
*Block*

**Parameters**
**addr** (*int*)

**dbg_repr**(*arch=None*)

**class** angr.**Block**

Bases: *Serializable*

Represents a basic block in a binary or a program.

**BLOCK_MAX_SIZE = 4096**

**__init__**(*addr*, *project=None*, *arch=None*, *size=None*, *max_size=None*, *byte_string=None*, *thumb=False*, *backup_state=None*, *extra_stop_points=None*, *opt_level=None*, *num_inst=None*, *traceflags=0*, *strict_block_end=None*, *collect_data_refs=False*, *cross_insn_opt=True*, *load_from_ro_regions=False*, *const_prop=False*, *initial_regs=None*, *skip_stmts=False*)

**Parameters**
**arch** (*Arch | None*)

**arch**

**addr**

**thumb**

**size**

**pp**(***kwargs*)

**set_initial_regs**()

**static reset_initial_regs**()

**property vex: IRSB | *IRSB***

**property vex_nostmt**

**property disassembly: *DisassemblerBlock***

Provide a disassembly object using whatever disassembler is available

**property capstone: *CapstoneBlock***

**property pcode: *PCodeBlock***

**property codenode**

**property bytes: bytes | None**

**property instructions: int**

**property instruction_addrs**

class angr.**Emulator**

Bases: object

Emulator is a utility that adapts an angr *SuccessorsEngine* to a more user-friendly interface for concrete execution. It only supports concrete execution.

Saftey: This class is not thread-safe. It should only be used in a single-threaded context. It can be safely shared between multiple threads, provided that only one thread is using it at a time.

**__init__**(*engine*, *init_state*)

**Parameters**

- **engine** (*SuccessorsEngine*) – The *SuccessorsEngine* to use for emulation.
- **init_state** (*SimState*) – The initial state to use for emulation.

**property state:** *SimState*

The current state of the emulator.

**property breakpoints:** set[int]

The set of currently set breakpoints.

**add_breakpoint**(*addr*)

Add a breakpoint at the given address.

**Parameters**
**addr** (int) – The address to set the breakpoint at.

**Return type**
None

**remove_breakpoint**(*addr*)

Remove a breakpoint at the given address, if present.

**Parameters**
**addr** (int) – The address to remove the breakpoint from.

**Return type**
None

**run**(*num_inst=None*)

Execute the emulator.

**Return type**
*EmulatorStopReason*

**Parameters**
**num_inst** (*int | None*)

class angr.**EmulatorStopReason**

Bases: Enum

Enum representing the reason for stopping the emulator.

**INSTRUCTION_LIMIT = 'instruction_limit'**

**BREAKPOINT = 'breakpoint'**

**NO_SUCCESSORS = 'no_successors'**

**MEMORY_ERROR = 'memory_error'**

**FAILURE = 'failure'**

**EXIT = 'exit'**

**class** angr.**ExplorationTechnique**

Bases: object

An ExplorationTechnique is a set of hooks for a simulation manager that assists in the implementation of new techniques in symbolic exploration.

Any number of these methods may be overridden by a subclass. To use an exploration technique, call `simgr.use_technique` with an *instance* of the technique.

**__init__**()

**setup**(*simgr*)

Perform any initialization on this manager you might need to do.

**Parameters**
**simgr** (*angr.SimulationManager*) – The simulation manager to which you have just been added

**step**(*simgr*, *stash='active'*, ***kwargs*)

Hook the process of stepping a stash forward. Should call `simgr.step(stash, **kwargs)` in order to do the actual processing.

**Parameters**

- **simgr** (*angr.SimulationManager*)
- **stash** (*str*)

**filter**(*simgr*, *state*, ***kwargs*)

Perform filtering on which stash a state should be inserted into.

If the state should be filtered, return the name of the stash to move the state to. If you want to modify the state before filtering it, return a tuple of the stash to move the state to and the modified state. To defer to the original categorization procedure, return the result of `simgr.filter(state, **kwargs)`

If the user provided a `filter_func` in their step or run command, it will appear here.

**Parameters**

- **simgr** (*angr.SimulationManager*)
- **state** (*angr.SimState*)

**selector**(*simgr*, *state*, ***kwargs*)

Determine if a state should participate in the current round of stepping. Return True if the state should be stepped, and False if the state should not be stepped. To defer to the original selection procedure, return the result of `simgr.selector(state, **kwargs)`.

If the user provided a `selector_func` in their step or run command, it will appear here.

**Parameters**

- **simgr** (*angr.SimulationManager*)
- **state** (*angr.SimState*)

**step_state**(*simgr*, *state*, ***kwargs*)

Determine the categorization of state successors into stashes. The result should be a dict mapping stash names to the list of successor states that fall into that stash, or None as a stash name to use the original stash name.

If you would like to directly work with a *SimSuccessors* object, you can obtain it with `simgr.successors(state, **kwargs)`. This is not recommended, as it denies other hooks the opportunity to look at the successors. Therefore, the usual technique is to call `simgr.step_state(state, **kwargs)` and then mutate the returned dict before returning it yourself.

..note:: This takes precedence over the *filter* hook - *filter* is only applied to states returned from here in the None stash.

**Parameters**

- **simgr** (*angr.SimulationManager*)
- **state** (*angr.SimState*)

**successors**(*simgr*, *state*, ***kwargs*)

Perform the process of stepping a state forward, returning a SimSuccessors object.

To defer to the original succession procedure, return the result of `simgr.successors(state, **kwargs)`. Be careful about not calling this method (e.g. calling `project.factory.successors` manually) as it denies other hooks the opportunity to instrument the step. Instead, you can mutate the kwargs for the step before calling the original, and mutate the result before returning it yourself.

If the user provided a `successor_func` in their step or run command, it will appear here.

**Parameters**

- **simgr** (*angr.SimulationManager*)
- **state** (*angr.SimState*)

**complete**(*simgr*)

Return whether or not this manager has reached a "completed" state, i.e. `SimulationManager.run()` should halt.

This is the one hook which is *not* subject to the nesting rules of hooks. You should *not* call `simgr.complete`, you should make your own decision and return True or False. Each of the techniques' completion checkers will be called and the final result will be compted with `simgr.completion_mode`.

**Parameters**

**simgr** (*angr.SimulationManager*)

**class** angr.**KnowledgeBase**

Bases: `object`

Represents a "model" of knowledge about an artifact.

Contains things like a CFG, data references, etc.

**functions:** *FunctionManager*

**comments:** *Comments*

**bookmarks:** *Bookmarks*

**variables:** *VariableManager*

**defs:** *KeyDefinitionManager*

**cfgs:** *CFGManager*

**types:** *TypesStore*

**propagations:** *PropagationManager*

**xrefs:** *XRefManager*

**decompilations:** *StructuredCodeManager*

**obfuscations:** *Obfuscations*

**rtdb:** *RuntimeDb*

**__init__**(*project*, *obj=None*, *name=None*)

**property callgraph**

**property unresolved_indirect_jumps**

**property resolved_indirect_jumps**

**has_plugin**(*name*)

**get_plugin**(*name*)

**register_plugin**(*name*, *plugin*)

**release_plugin**(*name*)

**get_knowledge**[*K:* KnowledgeBasePlugin](*requested_plugin_cls*)

Type inference safe method to request a knowledge base plugin Explicitly passing the type of the requested plugin achieves two things: 1. Every location using this plugin can be easily found with an IDE by searching explicit references to the type 2. Basic type inference can deduce the result type and properly type check usages of it

If there isn't already an instance of this class None will be returned to make it clear to the caller that there is no existing knowledge of this type yet. The code that initially creates this knowledge should use the *register_plugin* method to register the initial knowledge state :type requested_plugin_cls: type[K] :param requested_plugin_cls:

**Return type**
Optional[K]

**Returns**
Instance of the requested plugin class or null if it is not a known plugin

**Parameters**
**requested_plugin_cls** (type*[K]*)

**request_knowledge**[*K:* KnowledgeBasePlugin](*requested_plugin_cls*)

**Return type**
K

**Parameters**
**requested_plugin_cls** (type*[K]*)

class angr.KnowledgeBaseSnapshot

Bases: object

A restore point for a KnowledgeBase, so that the same project and CFG can be analyzed repeatedly (for example, decompiling one function under several option sets) from an identical starting state.

A snapshot records:

- the plugin table, as a shallow copy of the name-to-plugin mapping;
- by-value copies of the plugins named in included_plugins (default *COPIED_PLUGINS*) that exist at snapshot time;
- for each function resident in memory, its per-flavor prototypes, prototype sources, set of resolved flavors, and calling convention.

Without a rollback, a later Decompiler run sees the callee prototypes that Clinic installed on Function objects during an earlier run, inherits that run's variable numbering through dec_variables, and, when its cache parameters match, reuses the earlier decompilations entry instead of running the pipeline.

Functions are captured by object identity, and only the resident ones, because iterating a spilling function dict would evict the Function objects that callers hold. As a result, prototype changes on functions that were spilled at snapshot time and loaded later are not rolled back.

**COPIED_PLUGINS = ('types', 'custom_strings', 'callsite_prototypes', 'comments', 'variables')**

**__init__**(*kb*, *included_plugins=None*)

**Parameters**

- **kb** (*KnowledgeBase*) – The knowledge base to snapshot.
- **included_plugins** (Iterable[str] | None) – Names of the plugins to restore by value; the others are kept by reference. Defaults to *COPIED_PLUGINS*.

**restore**()

Roll the knowledge base back to this snapshot. Plugins created after the snapshot are removed. Each included plugin is replaced by a fresh copy of the snapshot's copy, so the snapshot itself is never modified. All other plugins are reinstated by reference, which means changes made to them in place are kept. Resident functions get their prototype state back. This method may be called any number of times.

**Return type**
None

class angr.LLMClient

Bases: object

A client for interacting with LLMs via pydantic-ai. Used by the decompiler to suggest improved variable names, function names, and types.

**__init__**(*model*, *api_key=None*, *api_base=None*, *max_tokens=4096*, *temperature=0.0*)

**Parameters**

- **model** (*str*)
- **api_key** (*str | None*)
- **api_base** (*str | None*)
- **max_tokens** (*int*)
- **temperature** (*float*)

**infer_provider**(*provider*)

Infer the provider from the provider name.

**Return type**
Provider[Any]

**Parameters**
**provider** (*str*)

**classmethod from_env**()

Create an LLMClient from environment variables.

Uses ANGR_LLM_MODEL (required), ANGR_LLM_API_KEY (optional), and ANGR_LLM_API_BASE (optional). Returns None if ANGR_LLM_MODEL is not set.

**Return type**
*LLMClient* | None

**completion**(*messages*, ***kwargs*)

Call the LLM with the given messages and return the response text.

**Return type**
str

**Parameters**
**messages** (*list[dict[str, str]]*)

**completion_structured**[*T*](*messages*, *output_type*, *raise_exc=False*, ***kwargs*)

Call the LLM with the given messages and return a validated Pydantic model. Returns None if the call fails.

**Parameters**

- **raise_exc** (bool) – If True, exceptions are propagated to the caller instead of being caught.
- **messages** (*list[dict[str, str]]*)
- **output_type** (type*[T]*)

**Return type**
Optional[T]

**completion_json**(*messages*, *raise_exc=False*, ***kwargs*)

Call the LLM and parse the response as JSON. Strips markdown code fences if present. Returns None on parse failure. Kept for backwards compatibility; prefer completion_structured().

**Parameters**

- **raise_exc** (bool) – If True, exceptions are propagated to the caller instead of being caught.
- **messages** (*list[dict[str, str]]*)

**Return type**
dict | None

**class** angr.**PTChunk**

Bases: *Chunk*

A chunk, inspired by the implementation of chunks in ptmalloc. Provides a representation of a chunk via a view into the memory plugin. For the chunk definitions and docs that this was loosely based off of, see glibc malloc/malloc.c, line 1033, as of commit 5a580643111ef6081be7b4c7bd1997a5447c903f.

Alternatively, take the following link. https://sourceware.org/git/?p=glibc.git;a=blob;f=malloc/malloc.c;h=67cdfd0ad2f003964cd0f7dfe3bcd85ca98528a7;hb=5a580643111ef6081be7b4c7bd1997a5447c903f#l1033

**Variables**

- **base** – the location of the base of the chunk in memory
- **state** – the program state that the chunk is resident in
- **heap** – the heap plugin that the chunk is managed by

**__init__**(*base*, *sim_state*, *heap=None*)

**set_size**(*size*, *is_free=None*)

Use this to set the size on a chunk. When the chunk is new (such as when a free chunk is shrunk to form an allocated chunk and a remainder free chunk) it is recommended that the is_free hint be used since setting the size depends on the chunk's freeness, and vice versa.

**Parameters**

- **size** – size of the chunk
- **is_free** – boolean indicating the chunk's freeness

**set_prev_freeness**(*is_free*)

Sets (or unsets) the flag controlling whether the previous chunk is free.

**Parameters**

**is_free** – if True, sets the previous chunk to be free; if False, sets it to be allocated

**is_prev_free**()

Returns a concrete state of the flag indicating whether the previous chunk is free or not. Issues a warning if that flag is symbolic and has multiple solutions, and then assumes that the previous chunk is free.

**Returns**

True if the previous chunk is free; False otherwise

**prev_size**()

Returns the size of the previous chunk, masking off what would be the flag bits if it were in the actual size field. Performs NO CHECKING to determine whether the previous chunk size is valid (for example, when the previous chunk is not free, its size cannot be determined).

**next_chunk**()

Returns the chunk immediately following (and adjacent to) this one, if it exists.

**Returns**

The following chunk, or None if applicable

**prev_chunk**()

Returns the chunk immediately prior (and adjacent) to this one, if that chunk is free. If the prior chunk is not free, then its base cannot be located and this method raises an error.

**Returns**

If possible, the previous chunk; otherwise, raises an error

**fwd_chunk**()

Returns the chunk following this chunk in the list of free chunks. If this chunk is not free, then it resides in no such list and this method raises an error.

**Returns**

If possible, the forward chunk; otherwise, raises an error

bck_chunk()

Returns the chunk backward from this chunk in the list of free chunks. If this chunk is not free, then it resides in no such list and this method raises an error.

**Returns**
If possible, the backward chunk; otherwise, raises an error

exception angr.PathUnreachableError

Bases: *AngrPathError*

class angr.PointerWrapper

Bases: object

__init__(*value*, *buffer=False*)

class angr.Project

Bases: object

This is the main class of the angr module. It is meant to contain a set of binaries and the relationships between them, and perform analyses on them.

**Parameters**

- **thing** – The path to the main executable object to analyze, or a CLE Loader object.
- **default_analysis_mode** – The mode of analysis to use by default. Defaults to 'symbolic'.
- **ignore_functions** – A list of function names that, when imported from shared libraries, should never be stepped into in analysis (calls will return an unconstrained value).
- **use_sim_procedures** – Whether to replace resolved dependencies for which simprocedures are available with said simprocedures.
- **exclude_sim_procedures_func** – A function that, when passed a function name, returns whether or not to wrap it with a simprocedure.
- **exclude_sim_procedures_list** – A list of functions to *not* wrap with simprocedures.
- **arch** – The target architecture (auto-detected otherwise).
- **simos** – a SimOS class to use for this project.
- **engine** – The SimEngine class to use for this project.
- **translation_cache** (*bool*) – If True, cache translated basic blocks rather than re-translating them.
- **selfmodifying_code** (bool) – Whether we aggressively support self-modifying code. When enabled, emulation will try to read code from the current state instead of the original memory, regardless of the current memory protections.
- **store_function** – A function that defines how the Project should be stored. Default to pickling.
- **load_function** – A function that defines how the Project should be loaded. Default to unpickling.
- **analyses_preset** (*angr.misc.PluginPreset*) – The plugin preset for the analyses provider (i.e. Analyses instance).

Any additional keyword arguments passed will be passed onto cle.Loader.

**Variables**

- **analyses** – The available analyses.

- **entry** – The program entrypoint.
- **factory** – Provides access to important analysis elements such as path groups and symbolic execution results.
- **filename** – The filename of the executable.
- **loader** – The program loader.
- **storage** – Dictionary of things that should be loaded/stored with the Project.

**__init__**(*thing*, *default_analysis_mode=None*, *ignore_functions=None*, *use_sim_procedures=True*, *exclude_sim_procedures_func=None*, *exclude_sim_procedures_list=()*, *arch=None*, *simos=None*, *engine=None*, *load_options=None*, *translation_cache=True*, *selfmodifying_code=False*, *support_selfmodifying_code=None*, *store_function=None*, *load_function=None*, *analyses_preset=None*, *eager_ifunc_resolution=None*, *cache_limits=None*, *rustc_version=None*, *rustc_optimization_level=None*, ***kwargs*)

**Parameters**

- **load_options** (*dict[str, Any] | None*)
- **selfmodifying_code** (*bool*)
- **support_selfmodifying_code** (*bool | None*)
- **cache_limits** (*dict[str, int | None] | None*)

**arch:** Arch

**property llm_client**

The LLM client for this project. Lazy-initialized from environment variables on first access. Set manually via `project.llm_client = LLMClient(...)` or configure via environment variables `ANGR_LLM_MODEL`, `ANGR_LLM_API_KEY`, `ANGR_LLM_API_BASE`.

**property kb**

**get_kb**(*name*)

**property analyses:** *AnalysesHubWithDefault*

**hook**(*addr*, *hook=None*, *length=0*, *kwargs=None*, *replace=False*)

Hook a section of code with a custom function. This is used internally to provide symbolic summaries of library functions, and can be used to instrument execution or to modify control flow.

When hook is not specified, it returns a function decorator that allows easy hooking. Usage:

```
# Assuming proj is an instance of angr.Project, we will add a custom hook at␣
↪the entry
# point of the project.
@proj.hook(proj.entry)
def my_hook(state):
    print("Welcome to execution!")
```

**Parameters**

- **addr** – The address to hook.
- **hook** – A `angr.project.Hook` describing a procedure to run at the given address. You may also pass in a SimProcedure class or a function directly and it will be wrapped in a Hook object for you.

- **length** – If you provide a function for the hook, this is the number of bytes that will be skipped by executing the hook by default.
- **kwargs** – If you provide a SimProcedure for the hook, these are the keyword arguments that will be passed to the procedure's *run* method eventually.
- **replace** (bool | None) – Control the behavior on finding that the address is already hooked. If true, silently replace the hook. If false (default), warn and do not replace the hook. If none, warn and replace the hook.

**is_hooked**(*addr*)

Returns True if *addr* is hooked.

**Parameters**
**addr** – An address.

**Return type**
bool

**Returns**
True if addr is hooked, False otherwise.

**hooked_by**(*addr*)

Returns the current hook for *addr*.

**Parameters**
**addr** – An address.

**Return type**
*SimProcedure* | None

**Returns**
None if the address is not hooked.

**unhook**(*addr*)

Remove a hook.

**Parameters**
**addr** – The address of the hook.

**hook_symbol**(*symbol_name*, *simproc*, *kwargs=None*, *replace=None*)

Resolve a dependency in a binary. Looks up the address of the given symbol, and then hooks that address. If the symbol was not available in the loaded libraries, this address may be provided by the CLE externs object.

Additionally, if instead of a symbol name you provide an address, some secret functionality will kick in and you will probably just hook that address, UNLESS you're on powerpc64 ABIv1 or some yet-unknown scary ABI that has its function pointers point to something other than the actual functions, in which case it'll do the right thing.

**Parameters**

- **symbol_name** – The name of the dependency to resolve.
- **simproc** – The SimProcedure instance (or function) with which to hook the symbol
- **kwargs** – If you provide a SimProcedure for the hook, these are the keyword arguments that will be passed to the procedure's *run* method eventually.
- **replace** (bool | None) – Control the behavior on finding that the address is already hooked. If true, silently replace the hook. If false, warn and do not replace the hook. If none (default), warn and replace the hook.

**Returns**
The address of the new symbol.

**Return type**
int

**symbol_hooked_by**(*symbol_name*)

Return the SimProcedure, if it exists, for the given symbol name.

**Parameters**
**symbol_name** (*str*) – Name of the symbol.

**Return type**
*SimProcedure* | None

**Returns**
None if the address is not hooked.

**is_symbol_hooked**(*symbol_name*)

Check if a symbol is already hooked.

**Parameters**
**symbol_name** (*str*) – Name of the symbol.

**Returns**
True if the symbol can be resolved and is hooked, False otherwise.

**Return type**
bool

**unhook_symbol**(*symbol_name*)

Remove the hook on a symbol. This function will fail if the symbol is provided by the extern object, as that would result in a state where analysis would be unable to cope with a call to this symbol.

**rehook_symbol**(*new_address*, *symbol_name*, *stubs_on_sync*)

Move the hook for a symbol to a specific address :type new_address: :param new_address: the new address that will trigger the SimProc execution :type symbol_name: :param symbol_name: the name of the symbol (f.i. strcmp ) :return: None

**execute**(**args*, ***kwargs*)

This function is a symbolic execution helper in the simple style supported by triton and manticore. It designed to be run after setting up hooks (see Project.hook), in which the symbolic state can be checked.

This function can be run in three different ways:

- When run with no parameters, this function begins symbolic execution from the entrypoint.
- It can also be run with a "state" parameter specifying a SimState to begin symbolic execution from.
- Finally, it can accept any arbitrary keyword arguments, which are all passed to project.factory.full_init_state.

If symbolic execution finishes, this function returns the resulting simulation manager.

**terminate_execution**()

Terminates a symbolic execution that was started with Project.execute().

**pcode_block_lifter**(*arch*)

Get the p-code basic block lifter, and therefore the Sleigh context, this project decodes *arch* with.

Sleigh records context variables per address, so the blocks of one binary decode with one context and no block of another binary touches it. *arch* is normally this project's own; a *Block* may name another, and decoding that with this project's context would answer for the wrong architecture, so it gets its own.

**Return type**
*PcodeBasicBlockLifter*

**Parameters**
**arch** (*Arch*)

`languages()`

**Return type**
list[str]

`property language_confidence: str | None`

How sure LanguageDetector is about `languages()` ("high", "medium" or "low"), or None when the language did not come from detection.

`property language_is_certain: bool`

Whether the detected language is solid enough to base language-specific ABI decisions on. A single matching symbol name is enough for LanguageDetector to report a language, but not enough to reinterpret every argument and return value in the binary.

`property is_rust_binary: bool`

Whether the main binary was identified as Rust with enough confidence to enable Rust-specific analyses.

`property is_go_binary: bool`

Whether the main binary was confidently identified as Go. Go's ABI differs from the platform default in every argument and return value, so a low-confidence detection is deliberately not enough.

`property go_version_range: GoVersionRange | None`

The (oldest, newest) Go releases the main binary may have been built with; see *angr.go.utils.version.go_version_range()*.

`property goos: str | None`

The main binary's GOOS, when its container format tells.

`get_function_cache_limit()`

Get the cache limit for function-level caches.

**Return type**
int | None

**Returns**
The cache limit, or None for disabling the cache.

`get_cfg_node_cache_limit()`

Get the cache limit for CFG node caches.

**Return type**
int | None

**Returns**
The cache limit, or None to disable the cache.

`executable_bytes()`

The number of bytes of executable code in the main object (sections, else segments, else the whole object).

**Return type**
int

**get_cfg_segment_budget**()

Byte budget for resident CFG graph segments (cache_limits key `cfg_segment_bytes`); a graph with a budget is paged to the RuntimeDb from the start. None keeps the graph fully resident. By default only binaries with more than CFG_PAGED_EXECUTABLE_BYTES of executable code are paged.

**Return type**
int | None

**class** angr.**Server**

Bases: object

Server implements the analysis server with a series of control interfaces exposed.

**Variables**

- **project** – An instance of angr.Project.
- **spill_yard** (*str*) – A directory to store spilled states.
- **db** (*str*) – Path of the database that stores information about spilled states.
- **max_workers** (*int*) – Maximum number of workers. Each worker starts a new process.
- **max_states** (*int*) – Maximum number of active states for each worker.
- **staging_max** (*int*) – Maximum number of inactive states that are kept into memory before spilled onto the disk and potentially be picked up by another worker.
- **bucketizer** (*bool*) – Use the Bucketizer exploration strategy.
- **_worker_exit_callback** – A method that will be called upon the exit of each worker.

**__init__**(*project*, *spill_yard=None*, *db=None*, *max_workers=None*, *max_states=10*, *staging_max=10*, *bucketizer=True*, *recursion_limit=1000*, *worker_exit_callback=None*, *techniques=None*, *add_options=None*, *remove_options=None*)

**inc_active_workers**()

**dec_active_workers**()

**stop**()

**property active_workers**

**property stopped**

**on_worker_exit**(*worker_id*, *stashes*)

**run**()

**exception** angr.**SimAbstractMemoryError**

Bases: *SimMemoryError*

**exception** angr.**SimActionError**

Bases: *SimError*

**class** angr.**SimCC**

Bases: object

A calling convention allows you to extract from a state the data passed from function to function by calls and returns. Most of the methods provided by SimCC that operate on a state assume that the program is just after a call but just before stack frame allocation, though this may be overridden with the *stack_base* parameter to each individual method.

This is the base class for all calling conventions.

**__init__**(*arch*, *x87_args=0*)

**Parameters**

- **arch** (Arch) – The Archinfo arch for this CC
- **x87_args** (int) – How many leading arguments are passed on the x87 stack (st(0), st(1), ...) and popped by the callee, as by MSVC's _CI* and _ftol helpers.

**ARG_REGS**: list[str] = []

**FP_ARG_REGS**: list[str] = []

**x87_args**: int = 0

**FP_RET_WHOLE_FUNCTION_SCAN**: bool = False

**STACKARG_SP_BUFF** = 0

**STACKARG_SP_DIFF** = 0

**CALLER_SAVED_REGS**: list[str] = []

**RETURN_ADDR**: *SimFunctionArgument* | None = None

**RETURN_VAL**: *SimFunctionArgument* | None = None

**OVERFLOW_RETURN_VAL**: *SimFunctionArgument* | None = None

**FP_RETURN_VAL**: *SimFunctionArgument* | None = None

**ARCH**: type[Arch] | None = None

**EXTRA_ARCHES**: tuple[type[Arch], ...] = ()

**CALLEE_CLEANUP** = False

**STACK_ALIGNMENT** = 1

**ARG_SLOT_SIZE**: int | None = None

**ARG_REG_SANITY_FILTER** = False

**STRICT_CALLER_SAVED_MATCH** = True

**SHARED_ARG_SLOTS** = False

**classmethod arg_reg_offsets**(*arch*)

Every register file offset covered by this convention's argument registers.

**Return type**
frozenset[int]

**Parameters**
**arch** (*Arch*)

**property arg_slot_size**: int

The width in bytes of one argument slot. See ARG_SLOT_SIZE.

property int_args

Iterate through all the possible arg positions that can only be used to store integer or pointer values.

Returns an iterator of SimFunctionArguments

property memory_args

Iterate through all the possible arg positions that can be used to store any kind of argument.

Returns an iterator of SimFunctionArguments

property fp_args

Iterate through all the possible arg positions that can only be used to store floating point values.

Returns an iterator of SimFunctionArguments

is_fp_arg(*arg*)

This should take a SimFunctionArgument instance and return whether or not that argument is a floating-point argument.

**Returns True for MUST be a floating point arg,**
False for MUST NOT be a floating point arg, None for when it can be either.

class ArgSession

Bases: object

A class to keep track of the state accumulated in laying parameters out into memory

both_iter

cc

fp_iter

int_iter

__init__(*cc*)

getstate()

setstate(*state*)

arg_session(*ret_ty*)

Return an arg session.

A session provides the control interface necessary to describe how integral and floating-point arguments are laid out into memory. The default behavior is that there are a finite list of int-only and fp-only argument slots, and an infinite number of generic slots, and when an argument of a given type is requested, the most slot available is used. If you need different behavior, subclass ArgSession.

You need to provide the return type of the function in order to kick off an arg layout session.

**Return type**
*ArgSession*

**Parameters**
**ret_ty** (SimType | *None*)

return_in_implicit_outparam(*ty*)

**Return type**
bool

**stack_space**(*args*)

**Parameters**
**args** – A list of SimFunctionArguments

**Returns**
The number of bytes that should be allocated on the stack to store all these args, NOT INCLUDING the return address.

**return_val**(*ty*, *perspective_returned=False*)
The location the return value is stored, based on its type.

**property return_addr**
The location the return address is stored.

**next_arg**(*session*, *arg_type*)

**Return type**
*SimFunctionArgument*

**Parameters**

- **session** (ArgSession)
- **arg_type** (SimType)

**static is_fp_value**(*val*)

**static guess_prototype**(*args*, *prototype=None*)
Come up with a plausible SimTypeFunction for the given args (as would be passed to e.g. setup_callsite).

You can pass a variadic function prototype in the *base_type* parameter and all its arguments will be used, only guessing types for the variadic arguments.

**arg_locs**(*prototype*)

**Return type**
list[*SimFunctionArgument*]

**x87_arg_locs**(*prototype*)
Locations of the leading arguments passed on the x87 stack.

**Return type**
list[*SimFunctionArgument*]

**get_args**(*state*, *prototype*, *stack_base=None*)

**set_return_val**(*state*, *val*, *ty*, *stack_base=None*, *perspective_returned=False*)

**setup_callsite**(*state*, *ret_addr*, *args*, *prototype*, *stack_base=None*, *alloc_base=None*, *grow_like_stack=True*)
This function performs the actions of the caller getting ready to jump into a function.

**Parameters**

- **state** – The SimState to operate on
- **ret_addr** – The address to return to when the called function finishes
- **args** – The list of arguments that that the called function will see
- **prototype** – The signature of the call you're making. Should include variadic args concretely.

- **stack_base** – An optional pointer to use as the top of the stack, circa the function entry point
- **alloc_base** – An optional pointer to use as the place to put excess argument data
- **grow_like_stack** – When allocating data at alloc_base, whether to allocate at decreasing addresses

The idea here is that you can provide almost any kind of python type in *args* and it'll be translated to a binary format to be placed into simulated memory. Lists (representing arrays) must be entirely elements of the same type and size, while tuples (representing structs) can be elements of any type and size. If you'd like there to be a pointer to a given value, wrap the value in a *PointerWrapper*.

If stack_base is not provided, the current stack pointer will be used, and it will be updated. If alloc_base is not provided, the stack base will be used and grow_like_stack will implicitly be True.

grow_like_stack controls the behavior of allocating data at alloc_base. When data from args needs to be wrapped in a pointer, the pointer needs to point somewhere, so that data is dumped into memory at alloc_base. If you set alloc_base to point to somewhere other than the stack, set grow_like_stack to False so that sequential allocations happen at increasing addresses.

**teardown_callsite**(*state*, *return_val=None*, *prototype=None*, *force_callee_cleanup=False*)

This function performs the actions of the callee as it's getting ready to return. It returns the address to return to.

**Parameters**

- **state** – The state to mutate
- **return_val** – The value to return
- **prototype** – The prototype of the given function
- **force_callee_cleanup** – If we should clean up the stack allocation for the arguments even if it's not the callee's job to do so

TODO: support the stack_base parameter from setup_callsite… ? Does that make sense in this context? Maybe it could make sense by saying that you pass it in as something like the "saved base pointer" value?

**static find_cc**(*arch*, *args*, *sp_delta*, *platform='Linux'*, *unused_hint=None*, *extra_pop=None*, *language=None*, *candidates=None*)

Pinpoint the best-fit calling convention and return the corresponding SimCC instance, or None if no fit is found.

**Parameters**

- **arch** (Arch) – An ArchX instance. Can be obtained from archinfo.
- **args** (list[*SimRegArg* | *SimStackArg*]) – A list of arguments. It may be updated by the first matched calling convention to remove non-argument arguments.
- **sp_delta** (int) – The change of stack pointer before and after the call is made.
- **extra_pop** (int | None) – The number of bytes that are popped by the callee. This is used to distinguish between callee-cleanup and caller-cleanup conventions. None means unknown, in which case callee-cleanup conventions with stack arguments are only matched if no other convention fits the arguments.
- **language** (str | None) – The source language of the binary (e.g. "go"), if known. Languages with their own ABI are matched against that ABI alone.

- **candidates** (list[type[*SimCC*]] | None) – The conventions to consider, overriding the lookup by architecture, platform and language (e.g. the one Go convention a binary's Go release uses).
- **platform** (*str | None*)
- **unused_hint** (*list[SimRegArg] | None*)

**Return type**
*SimCC* | None

**Returns**
A calling convention instance, or None if none of the SimCC subclasses seems to fit the arguments provided.

**classmethod arches**()

**Return type**
tuple[type[Arch], ...]

**get_arg_info**(*state*, *prototype*)

This is just a simple wrapper that collects the information from various locations prototype is as passed to self.arg_locs and self.get_args :type state: angr.SimState :param state: The state to evaluate and extract the values from :return: A list of tuples, where the nth tuple is (type, name, location, value) of the nth argument

class angr.SimFile

Bases: *SimFileBase*, *DefaultMemory*

The normal SimFile is meant to model files on disk. It subclasses SimSymbolicMemory so loads and stores to/from it are very simple.

**Parameters**

- **name** – The name of the file
- **content** – Optional initial content for the file as a string or bitvector
- **size** – Optional size of the file. If content is not specified, it defaults to zero
- **has_end** – Whether the size boundary is treated as the end of the file or a frontier at which new content will be generated. If unspecified, will pick its value based on options.FILES_HAVE_EOF. Another caveat is that if the size is also unspecified this value will default to False.
- **seekable** – Optional bool indicating whether seek operations on this file should succeed, default True.
- **writable** – Whether writing to this file is allowed
- **concrete** – Whether or not this file contains mostly concrete data. Will be used by some SimProcedures to choose how to handle variable-length operations like fgets.

**Variables**

**has_end** – Whether this file has an EOF

__init__(*name=None*, *content=None*, *size=None*, *has_end=None*, *seekable=True*, *writable=True*, *ident=None*, *concrete=None*, ***kwargs*)

property category

reg, mem, or file.

**Type**

Return the category of this SimMemory instance. It can be one of the three following categories

property size

The number of data bytes stored by the file at present. May be a symbolic value.

concretize(***kwargs*)

Return a concretization of the contents of the file, as a flat bytestring.

class angr.SimFileBase

Bases: *SimStatePlugin*

SimFiles are the storage mechanisms used by SimFileDescriptors.

Different types of SimFiles can have drastically different interfaces, and as a result there's not much that can be specified on this base class. All the read and write methods take a `pos` argument, which may have different semantics per-class. `0` will always be a valid position to use, though, and the next position you should use is part of the return tuple.

Some simfiles are "streams", meaning that the position that reads come from is determined not by the position you pass in (it will in fact be ignored), but by an internal variable. This is stored as `.pos` if you care to read it. Don't write to it. The same lack-of-semantics applies to this field as well.

**Variables**

- **name** – The name of the file. Purely for cosmetic purposes
- **ident** – The identifier of the file, typically autogenerated from the name and a nonce. Purely for cosmetic purposes, but does appear in symbolic values autogenerated in the file.
- **seekable** – Bool indicating whether seek operations on this file should succeed. If this is True, then `pos` must be a number of bytes from the start of the file.
- **writable** – Bool indicating whether writing to this file is allowed.
- **pos** – If the file is a stream, this will be the current position. Otherwise, None.
- **concrete** – Whether or not this file contains mostly concrete data. Will be used by some SimProcedures to choose how to handle variable-length operations like fgets.
- **file_exists** – Set to False, if file does not exists, set to a claripy Bool if unknown, default True.

seekable = False

pos = None

__init__(*name=None*, *writable=True*, *ident=None*, *concrete=False*, *file_exists=True*, ***kwargs*)

static make_ident(*name*)

concretize(***kwargs*)

Return a concretization of the contents of the file. The type of the return value of this method will vary depending on which kind of SimFile you're using.

read(*pos*, *size*, ***kwargs*)

Read some data from the file.

**Parameters**

- **pos** – The offset in the file to read from.
- **size** – The size to read. May be symbolic.

**Returns**

A tuple of the data read (a bitvector of the length that is the maximum length of the read), the actual size of the read, and the new file position pointer.

write(*pos*, *data*, *size=None*, ***kwargs*)

Write some data to the file.

**Parameters**

- **pos** – The offset in the file to write to. May be ignored if the file is a stream or device.
- **data** – The data to write as a bitvector
- **size** – The optional size of the data to write. If not provided will default to the length of the data. Must be constrained to less than or equal to the size of the data.

**Returns**
The new file position pointer.

**property size**

The number of data bytes stored by the file at present. May be a symbolic value.

**class** angr.**SimFileDescriptor**

Bases: *SimFileDescriptorBase*

A simple file descriptor forwarding reads and writes to a SimFile. Contains information about the current opened state of the file, such as the flags or (if relevant) the current position.

**Variables**

- **file** – The SimFile described to by this descriptor
- **flags** – The mode that the file descriptor was opened with, a bitfield of flags

**__init__**(*simfile*, *flags=0*)

**concretize**(***kwargs*)

Return a concretization of the underlying file. Returns whatever format is preferred by the file.

**property file_exists**

This should be True in most cases. Only if we opened an fd of unknown existence, ALL_FILES_EXIST is False and ANY_FILE_MIGHT_EXIST is True, this is a symbolic boolean.

**property read_storage**

Return the SimFile backing reads from this fd

**property write_storage**

Return the SimFile backing writes to this fd

**property read_pos**

Return the current position of the read file pointer.

If the underlying read file is a stream, this will return the position of the stream. Otherwise, will return the position of the file descriptor in the file.

**property write_pos**

Return the current position of the read file pointer.

If the underlying read file is a stream, this will return the position of the stream. Otherwise, will return the position of the file descriptor in the file.

**class** angr.**SimFileDescriptorDuplex**

Bases: *SimFileDescriptorBase*

A file descriptor that refers to two file storage mechanisms, one to read from and one to write to. As a result, operations like seek, eof, etc no longer make sense.

**Parameters**

- **read_file** – The SimFile to read from
- **write_file** – The SimFile to write to

__init__(*read_file*, *write_file*)

concretize(***kwargs*)

Return a concretization of the underlying files, as a tuple of (read file, write file).

property read_storage

Return the SimFile backing reads from this fd

property write_storage

Return the SimFile backing writes to this fd

property read_pos

Return the current position of the read file pointer.

If the underlying read file is a stream, this will return the position of the stream. Otherwise, will return the position of the file descriptor in the file.

property write_pos

Return the current position of the read file pointer.

If the underlying read file is a stream, this will return the position of the stream. Otherwise, will return the position of the file descriptor in the file.

exception angr.SimFileError

Bases: *SimMemoryError*, *SimFilesystemError*

class angr.SimFileStream

Bases: *SimFile*

A specialized SimFile that uses a flat memory backing, but functions as a stream, tracking its position internally.

The pos argument to the read and write methods will be ignored, and will return None. Instead, there is an attribute pos on the file itself, which will give you what you want.

**Parameters**

- **name** – The name of the file, for cosmetic purposes
- **pos** – The initial position of the file, default zero
- **kwargs** – Any other keyword arguments will go on to the SimFile constructor.

**Variables**

**pos** – The current position in the file.

__init__(*name=None*, *content=None*, *pos=0*, ***kwargs*)

exception angr.SimFilesystemError

Bases: *SimError*

class angr.SimHeapBrk

Bases: *SimHeapBase*

SimHeapBrk represents a trivial heap implementation based on the Unix *brk* system call. This type of heap stores virtually no metadata, so it is up to the user to determine when it is safe to release memory. This also means that it does not properly support standard heap operations like *realloc*.

This heap implementation is a holdover from before any more proper implementations were modelled. At the time, various libc (or win32) SimProcedures handled the heap in the same way that this plugin does now. To make future heap implementations plug-and-playable, they should implement the necessary logic themselves, and dependent SimProcedures should invoke a method by the same name as theirs (prepended with an underscore)

upon the heap plugin. Depending on the heap implementation, if the method is not supported, an error should be raised.

Out of consideration for the original way the heap was handled, this plugin implements functionality for all relevant SimProcedures (even those that would not normally be supported together in a single heap implementation).

**Variables**
**heap_location** – the address of the top of the heap, bounding the allocations made starting from *heap_base*

**__init__**(*heap_base=None*, *heap_size=None*)

**allocate**(*sim_size*)

The actual allocation primitive for this heap implementation. Increases the position of the break to allocate space. Has no guards against the heap growing too large.

**Parameters**
**sim_size** – a size specifying how much to increase the break pointer by

**Returns**
a pointer to the previous break position, above which there is now allocated space

**release**(*sim_size*)

The memory release primitive for this heap implementation. Decreases the position of the break to deallocate space. Guards against releasing beyond the initial heap base.

The mapped extent of the heap is deliberately not shrunk here. Unmapping the released pages would discard their contents, so a release followed by an allocation would hand back blank memory instead of the old bytes, which is a behavior change; and since the extent only ever grows to the high-water mark of the break, keeping it costs nothing beyond what the program already asked for.

**Parameters**
**sim_size** – a size specifying how much to decrease the break pointer by (may be symbolic or not)

**exception** angr.**SimHeapError**

Bases: *SimStateError*

**class** angr.**SimHeapPTMalloc**

Bases: *SimHeapFreelist*

A freelist-style heap implementation inspired by ptmalloc. The chunks used by this heap contain heap metadata in addition to user data. While the real-world ptmalloc is implemented using multiple lists of free chunks (corresponding to their different sizes), this more basic model uses a single list of chunks and searches for free chunks using a first-fit algorithm.

**NOTE:** The plugin must be registered using `register_plugin` with name `heap` in order to function properly.

**Variables**

- **heap_base** – the address of the base of the heap in memory
- **heap_size** – the total size of the main memory region managed by the heap in memory
- **mmap_base** – the address of the region from which large mmap allocations will be made
- **free_head_chunk** – the head of the linked list of free chunks in the heap

**__init__**(*heap_base=None*, *heap_size=None*)

chunk_from_mem(*ptr*)

Given a pointer to a user payload, return the base of the chunk associated with that payload (i.e. the chunk pointer). Returns None if ptr is null.

**Parameters**
**ptr** – a pointer to the base of a user payload in the heap

**Returns**
a pointer to the base of the associated heap chunk, or None if ptr is null

class angr.SimHostFilesystem

Bases: *SimConcreteFilesystem*

Simulated mount that makes some piece from the host filesystem available to the guest.

**Parameters**

- **host_path** (*str*) – The path on the host to mount
- **pathsep** (*str*) – The host path separator character, default os.path.sep

__init__(*host_path=None*, ***kwargs*)

exception angr.SimIRSBError

Bases: *SimEngineError*

exception angr.SimIRSBNoDecodeError

Bases: *SimIRSBError*

Bases: *SimStateError*

exception angr.SimMissingTempError

Bases: *SimValueError*, IndexError

class angr.SimMount

Bases: *SimStatePlugin*

This is the base class for "mount points" in angr's simulated filesystem. Subclass this class and give it to the filesystem to intercept all file creations and opens below the mountpoint. Since this a SimStatePlugin you may also want to implement set_state, copy, merge, etc.

get(*path_elements*)

Implement this function to instrument file lookups.

**Parameters**
**path_elements** – A list of path elements traversing from the mountpoint to the file

**Returns**
A SimFile, or None

**insert**(*path_elements*, *simfile*)

Implement this function to instrument file creation.

**Parameters**

- **path_elements** – A list of path elements traversing from the mountpoint to the file
- **simfile** – The file to insert

**Returns**
A bool indicating whether the insert occurred

**delete**(*path_elements*)

Implement this function to instrument file deletion.

**Parameters**
**path_elements** – A list of path elements traversing from the mountpoint to the file

**Returns**
A bool indicating whether the delete occurred

**lookup**(*sim_file*)

Look up the path of a SimFile in the mountpoint

**Parameters**
**sim_file** – A SimFile object needs to be looked up

**Returns**
A string representing the path of the file in the mountpoint Or None if the SimFile does not exist in the mountpoint

**class** angr.**SimOS**

Bases: object

A class describing OS/arch-level configuration.

**__init__**(*project*, *name=None*)

**Parameters**

- **project** (Project)
- **name** (*str | None*)

**name:** str | None

**configure_project**()

Configure the project to set up global settings (like SimProcedures).

**state_blank**(*addr=None*, *initial_prefix=None*, *brk=None*, *stack_end=None*, *stack_size=8388608*, *stdin=None*, *thread_idx=None*, *permissions_backer=None*, ***kwargs*)

Initialize a blank state.

All parameters are optional.

**Parameters**

- **addr** – The execution start address.
- **initial_prefix**
- **stack_end** – The end of the stack (i.e., the byte after the last valid stack address).
- **stack_size** – The number of bytes to allocate for stack space

- **brk** – The address of the process' break.

**Returns**
The initialized SimState.

Any additional arguments will be passed to the SimState constructor

**state_entry**(***kwargs*)

**state_full_init**(***kwargs*)

**state_call**(*addr*, **args*, ***kwargs*)

**prepare_call_state**(*calling_state*, *initial_state=None*, *preserve_registers=()*, *preserve_memory=()*)

This function prepares a state that is executing a call instruction. If given an initial_state, it copies over all of the critical registers to it from the calling_state. Otherwise, it prepares the calling_state for action.

This is mostly used to create minimalistic for CFG generation. Some ABIs, such as MIPS PIE and x86 PIE, require certain information to be maintained in certain registers. For example, for PIE MIPS, this function transfer t9, gp, and ra to the new state.

**prepare_function_symbol**(*symbol_name*, *basic_addr=None*)

Prepare the address space with the data necessary to perform relocations pointing to the given symbol

Returns a 2-tuple. The first item is the address of the function code, the second is the address of the relocation target.

**handle_exception**(*successors*, *engine*, *exception*)

Perform exception handling. This method will be called when, during execution, a SimException is thrown. Currently, this can only indicate a segfault, but in the future it could indicate any unexpected exceptional behavior that can't be handled by ordinary control flow.

The method may mutate the provided SimSuccessors object in any way it likes, or re-raise the exception.

**Parameters**

- **successors** – The SimSuccessors object currently being executed on
- **engine** – The engine that was processing this step
- **exception** – The actual exception object

**syscall**(*state*, *allow_unsupported=True*)

**Return type**
*SimProcedure* | None

**Parameters**

- **state** (SimState)
- **allow_unsupported** (*bool*)

**syscall_abi**(*state*)

**Return type**
str | None

**Parameters**
**state** (SimState)

**syscall_cc**(*state*)

**Return type**
*SimCCSyscall* | None

**Parameters**
**state** (SimState)

**is_syscall_addr**(*addr*)

**Return type**
bool

**syscall_from_addr**(*addr*, *allow_unsupported=True*)

**Return type**
*SimProcedure* | None

**syscall_from_number**(*number*, *allow_unsupported=True*, *abi=None*)

**Return type**
*SimProcedure* | None

**setup_gdt**(*state*, *gdt*)

Write the GlobalDescriptorTable object in the current state memory

**Parameters**

- **state** – state in which to write the GDT
- **gdt** – GlobalDescriptorTable object

**Returns**

**generate_gdt**(*fs*, *gs*, *fs_size=4294967295*, *gs_size=4294967295*)

Generate a GlobalDescriptorTable object and populate it using the value of the gs and fs register

**Parameters**

- **fs** – value of the fs segment register
- **gs** – value of the gs segment register
- **fs_size** – size of the fs segment register
- **gs_size** – size of the gs segment register

**Returns**
gdt a GlobalDescriptorTable object

**exception** angr.**SimOperationError**

Bases: *SimError*

**class** angr.**SimPackets**

Bases: *SimFileBase*

The SimPackets is meant to model inputs whose content is delivered a series of asynchronous chunks. The data is stored as a list of read or write results. For symbolic sizes, state.libc.max_packet_size will be respected. If the SHORT_READS option is enabled, reads will return a symbolic size constrained to be less than or equal to the requested size.

A SimPackets cannot be used for both reading and writing - for socket objects that can be both read and written to you should use a file descriptor to multiplex the read and write operations into two separate file storage mechanisms.

**Parameters**

- **name** – The name of the file, for cosmetic purposes
- **write_mode** – Whether this file is opened in read or write mode. If this is unspecified it will be autodetected.
- **content** – Some initial content to use for the file. Can be a list of bytestrings or a list of tuples of content ASTs and size ASTs.

**Variables**

- **write_mode** – See the eponymous parameter
- **content** – A list of packets, as tuples of content ASTs and size ASTs.

**__init__**(*name*, *write_mode=None*, *content=None*, *writable=True*, *ident=None*, ***kwargs*)

**property size**

The number of data bytes stored by the file at present. May be a symbolic value.

**concretize**(***kwargs*)

Returns a list of the packets read or written as bytestrings.

**read**(*pos*, *size*, ***kwargs*)

Read a packet from the stream.

**Parameters**

- **pos** (*int*) – The packet number to read from the sequence of the stream. May be None to append to the stream.
- **size** – The size to read. May be symbolic.
- **short_reads** – Whether to replace the size with a symbolic value constrained to less than or equal to the original size. If unspecified, will be chosen based on the state option.

**Returns**

A tuple of the data read (a bitvector of the length that is the maximum length of the read) and the actual size of the read.

**write**(*pos*, *data*, *size=None*, *events=True*, ***kwargs*)

Write a packet to the stream.

**Parameters**

- **pos** (*int*) – The packet number to write in the sequence of the stream. May be None to append to the stream.
- **data** – The data to write, as a string or bitvector.
- **size** – The optional size to write. May be symbolic; must be constrained to at most the size of data.

**Returns**

The next packet to use after this

**class** angr.**SimPacketsStream**

Bases: *SimPackets*

A specialized SimPackets that tracks its position internally.

The pos argument to the read and write methods will be ignored, and will return None. Instead, there is an attribute `pos` on the file itself, which will give you what you want.

**Parameters**

- **name** – The name of the file, for cosmetic purposes
- **pos** – The initial position of the file, default zero
- **kwargs** – Any other keyword arguments will go on to the SimPackets constructor.

**Variables**

**pos** – The current position in the file.

**__init__**(*name*, *pos=0*, ***kwargs*)

**exception** angr.**SimPosixError**

Bases: *SimStateError*

**class** angr.**SimProcedure**

Bases: object

A SimProcedure is a wonderful object which describes a procedure to run on a state.

You may subclass SimProcedure and override `run()`, replacing it with mutating `self.state` however you like, and then either returning a value or jumping away somehow.

A detailed discussion of programming SimProcedures may be found at https://docs.angr.io/extending-angr/simprocedures

**Parameters**

- **arch** – The architecture to use for this procedure
- **symbolic_return** – Whether the procedure's return value should be stubbed into a single symbolic variable constratined to the real return value
- **returns** – Whether the procedure should return to its caller afterwards
- **is_syscall** – Whether this procedure is a syscall
- **num_args** – The number of arguments this procedure should extract
- **display_name** – The name to use when displaying this procedure
- **library_name** – The name of the library from which the function we're emulating comes
- **cc** (*SimCC* | None) – The SimCC to use for this procedure
- **sim_kwargs** – Additional keyword arguments to be passed to run()
- **is_function** – Whether this procedure emulates a function

The following class variables should be set if necessary when implementing a new SimProcedure:

**Variables**

- **NO_RET** – Set this to true if control flow will never return from this function
- **DYNAMIC_RET** – Set this to true if whether the control flow returns from this function or not depends on the context (e.g., libc's error() call). Must implement dynamic_returns() method.
- **ADDS_EXITS** – Set this to true if you do any control flow other than returning
- **IS_FUNCTION** – Does this procedure simulate a function? True by default
- **ARGS_MISMATCH** – Does this procedure have a different list of arguments than what is provided in the function specification? This may happen when we manually extract arguments in the run() method of a SimProcedure. False by default.

- **local_vars** (tuple[str, ...]) – If you use `self.call()`, set this to a list of all the local variable names in your class. They will be restored on return.

The following instance variables are available when working with simprocedures from the inside or the outside:

**Variables**

- **project** – The associated angr project
- **arch** – The associated architecture
- **addr** – The linear address at which the procedure is executing
- **cc** – The calling convention in use for engaging with the ABI
- **canonical** – The canonical version of this SimProcedure. Procedures are deepcopied for many reasons, including to be able to store state related to a specific run and to be able to hook continuations.
- **kwargs** – Any extra keyword arguments used to construct the procedure; will be passed to `run`
- **display_name** – See the eponymous parameter
- **library_name** – See the eponymous parameter
- **abi** – If this is a syscall simprocedure, which ABI are we using to map the syscall numbers?
- **symbolic_return** – See the eponymous parameter
- **syscall_number** – If this procedure is a syscall, the number will be populated here.
- **returns** – See eponymous parameter and NO_RET cvar
- **is_syscall** – See eponymous parameter
- **is_function** – See eponymous parameter and cvar
- **is_stub** – See eponymous parameter
- **is_continuation** – Whether this procedure is the original or a continuation resulting from `self.call()`
- **continuations** – A mapping from name to each known continuation
- **run_func** – The name of the function implementing the procedure. "run" by default, but different in continuations.
- **num_args** – The number of arguments to the procedure. If not provided in the parameter, extracted from the definition of `self.run`

The following instance variables are only used in a copy of the procedure that is actually executing on a state:

**Variables**

- **state** (*SimState*) – The SimState we should be mutating to perform the procedure
- **successors** – The SimSuccessors associated with the current step
- **arguments** – The function arguments, deserialized from the state
- **arg_session** (*ArgSession* | int | None) – The ArgSession that was used to parse arguments out of the state, in case you need it for varargs
- **use_state_arguments** – Whether we're using arguments extracted from the state or manually provided
- **ret_to** – The current return address

- **ret_expr** – The computed return value
- **call_ret_expr** – The return value from having used `self.call()`
- **inhibit_autoret** – Whether we should avoid automatically adding an exit for returning once the run function ends
- **arg_session** – The ArgSession object that was used to extract the runtime argument values. Useful for if you want to extract variadic args.

**__init__**(*project=None*, *cc=None*, *prototype=None*, *symbolic_return=None*, *returns=None*, *is_syscall=False*, *is_stub=False*, *num_args=None*, *display_name=None*, *library_name=None*, *is_function=None*, ***kwargs*)

**Parameters**

- **project** (Project | *None*)
- **cc** (SimCC | *None*)
- **prototype** (*str* | SimTypeFunction | *None*)

**state:** *SimState*

**execute**(*state*, *successors=None*, *arguments=None*, *ret_to=None*)

Call this method with a SimState and a SimSuccessors to execute the procedure.

Alternately, successors may be none if this is an inline call. In that case, you should provide arguments to the function.

**make_continuation**(*name*)

**NO_RET = False**

**DYNAMIC_RET = False**

**ADDS_EXITS = False**

**IS_FUNCTION = True**

**ARGS_MISMATCH = False**

**ALT_NAMES = None**

**local_vars:** tuple[str, ...] = ()

**run**(**args*, ***kwargs*)

Implement the actual procedure here!

**Return type**
Any

**static_exits**(*blocks*, ***kwargs*)

Get new exits by performing static analysis and heuristics. This is a fast and best-effort approach to get new exits for scenarios where states are not available (e.g. when building a fast CFG).

**Parameters**
**blocks** (*list*) – Blocks that are executed before reaching this SimProcedure.

**Returns**
A list of dicts. Each dict should contain the following entries: 'address', 'jumpkind', and 'namehint'.

**Return type**
list

**dynamic_returns**(*blocks*, ***kwargs*)

Determines if a call to this function returns or not by performing static analysis and heuristics.

**Parameters**
**blocks** – Blocks that are executed before reaching this SimProcedure.

**Return type**
bool

**Returns**
True if the call returns, False otherwise.

**property should_add_successors**

**set_args**(*args*)

**va_arg**(*ty*, *index=None*)

**inline_call**(*procedure*, **arguments*, ***kwargs*)

Call another SimProcedure in-line to retrieve its return value. Returns an instance of the procedure with the ret_expr property set.

**Parameters**

- **procedure** – The class of the procedure to execute
- **arguments** – Any additional positional args will be used as arguments to the procedure call
- **sim_kwargs** – Any additional keyword args will be passed as sim_kwargs to the procedure constructor

**fix_prototype_returnty**(*ret_size*)

**ret**(*expr=None*)

Add an exit representing a return from this function. If this is not an inline call, grab a return address from the state and jump to it. If this is not an inline call, set a return expression with the calling convention.

**call**(*addr*, *args*, *continue_at*, *cc=None*, *prototype=None*, *jumpkind='Ijk_Call'*)

Add an exit representing calling another function via pointer.

**Parameters**

- **addr** – The address of the function to call
- **args** – The list of arguments to call the function with
- **continue_at** – Later, when the called function returns, execution of the current procedure will continue in the named method.
- **cc** – Optional: use this calling convention for calling the new function. Default is to use the current convention.
- **prototype** – Optional: The prototype to use for the call. Will default to all-ints.

**jump**(*addr*, *jumpkind='Ijk_Boring'*)

Add an exit representing jumping to an address.

**exit**(*exit_code*)

Add an exit representing terminating the program.

class angr.SimState

Bases: *PluginHub*[*SimStatePlugin*], Generic[IPTypeConc, IPTypeSym]

The SimState represents the state of a program, including its memory, registers, and so forth.

**Parameters**

**project** (*Project*) – The project instance.

**Variables**

- **regs** (*SimRegNameView*) – A convenient view of the state's registers, where each register is a property
- **mem** – A convenient view of the state's memory, a *angr.state_plugins.view.SimMemView*
- **registers** (*DefaultMemory*) – The state's register file as a flat memory region
- **memory** (*DefaultMemory*) – The state's memory as a flat memory region
- **solver** (*SimSolver*) – The symbolic solver and variable manager for this state
- **inspect** – The breakpoint manager, a *angr.state_plugins.inspect.SimInspector*

- **log** – Information about the state's history
- **scratch** (*SimStateScratch*) – Information about the current execution step
- **posix** – MISNOMER: information about the operating system or environment model
- **fs** (*SimFilesystem*) – The current state of the simulated filesystem
- **libc** (*SimStateLibc*) – Information about the standard library we are emulating
- **cgc** – Information about the cgc environment
- **uc_manager** – Control of under-constrained symbolic execution
- **unicorn** – Control of the Unicorn Engine

**Parameters**

- **project** (Project)
- **plugins** (*dict[str, SimStatePlugin] | None*)
- **mode** (*str | None*)
- **options** (*set[str] | list[str] | SimStateOptions | None*)
- **add_options** (*set[str] | None*)
- **remove_options** (*set[str] | None*)

- **default_permissions** (int)
- **stack_perms** (int | None)
- **stack_end** (int | None)
- **stack_size** (int | None)

**property plugins**

**property ip**

Get the instruction pointer expression, trigger SimInspect breakpoints, and generate SimActions. Use `_ip` to not trigger breakpoints or generate actions.

**Returns**
an expression

**property addr: IPTypeConc**

Get the concrete address of the instruction pointer, without triggering SimInspect breakpoints or generating SimActions. An integer is returned, or an exception is raised if the instruction pointer is symbolic.

**Returns**
an int

**Setter accepts**
int | SootAddressDescriptor | tuple[int, int]

**property arch: Arch**

The architecture of the state. This is the project's architecture, except for JavaVM projects with JNI support, where it is either the Soot or the native architecture, depending on whether the current ip is a Soot address.

**property javavm_memory**

In case of an JavaVM with JNI support, a state can store the memory plugin twice; one for the native and one for the java view of the state.

**Returns**
The JavaVM view of the memory plugin.

**property javavm_registers**

In case of an JavaVM with JNI support, a state can store the registers plugin twice; one for the native and one for the java view of the state.

**Returns**
The JavaVM view of the registers plugin.

**simplify**(**args*)

Simplify this state's constraints.

**add_constraints**(**constraints*)

Add some constraints to the state.

You may pass in any number of symbolic booleans as variadic positional arguments.

**satisfiable**(***kwargs*)

Whether the state's constraints are satisfiable

**downsize**()

Clean up after the solver engine. Calling this when a state no longer needs to be solved on will reduce memory usage.

**step**(***kwargs*)

Perform a step of symbolic execution using this state. Any arguments to *AngrObjectFactory.successors* can be passed to this.

**Returns**
A SimSuccessors object categorizing the results of the step.

**block**(**args*, ***kwargs*)

Represent the basic block at this state's instruction pointer. Any arguments to *AngrObjectFactory.block* can ba passed to this.

**Returns**
A Block object describing the basic block of code at this point.

**copy**()

Returns a copy of the state.

**merge**(**others*, ***kwargs*)

Merges this state with the other states. Returns the merging result, merged state, and the merge flag.

**Parameters**

- **states** – the states to merge
- **merge_conditions** – a tuple of the conditions under which each state holds
- **common_ancestor** – a state that represents the common history between the states being merged. Usually it is only available when EFFICIENT_STATE_MERGING is enabled, otherwise weak-refed states might be dropped from state history instances.
- **plugin_whitelist** – a list of plugin names that will be merged. If this option is given and is not None, any plugin that is not inside this list will not be merged, and will be created as a fresh instance in the new state.
- **common_ancestor_history** – a SimStateHistory instance that represents the common history between the states being merged. This is to allow optimal state merging when EFFICIENT_STATE_MERGING is disabled.

**Returns**
(merged state, merge flag, a bool indicating if any merging occurred)

**reg_concrete**(**args*, ***kwargs*)

Returns the contents of a register but, if that register is symbolic, raises a SimValueError.

**mem_concrete**(**args*, ***kwargs*)

Returns the contents of a memory but, if the contents are symbolic, raises a SimValueError.

**stack_push**(*thing*)

Push 'thing' to the stack, writing the thing to memory and adjusting the stack pointer.

**stack_pop**()

Pops from the stack and returns the popped thing. The length will be the architecture word size.

**stack_read**(*offset*, *length*, *bp=False*)

Reads length bytes, at an offset into the stack.

**Parameters**

- **offset** – The offset from the stack pointer.
- **length** – The number of bytes to read.
- **bp** – If True, offset from the BP instead of the SP. Default: False.

**make_concrete_int**(*expr*)

**dbg_print_stack**(*depth=None*, *sp=None*)

Only used for debugging purposes. Return the current stack info in formatted string. If depth is None, the current stack frame (from sp to bp) will be printed out.

**set_mode**(*mode*)

**property thumb**

**exception** angr.**SimStateError**

Bases: *SimError*

**exception** angr.**SimStateOptionsError**

Bases: *SimError*

**class** angr.**SimStatePlugin**

Bases: object

This is a base class for SimState plugins. A SimState plugin will be copied along with the state when the state is branched. They are intended to be used for things such as tracking open files, tracking heap details, and providing storage and persistence for SimProcedures.

**__init__**()

**Return type**
None

**state:** *SimState*[Any, Any]

**set_state**(*state*)

Sets a new state (for example, if the state has been branched)

**Return type**
None

**static memo**[*S_co*](*f*)

A decorator function you should apply to copy

**Return type**
_CopyFunc[S_co]

**Parameters**
**f**(*Callable[[Any, dict[int, Any]], S_co]*)

**copy**(*_memo*)

Should return a copy of the plugin without any state attached. Should check the memo first, and add itself to memo if it ends up making a new copy.

In order to simplify using the memo, you should annotate implementations of this function with `SimStatePlugin.memo`

The base implementation of this function constructs a new instance of the plugin's class without calling its initializer. If you super-call down to it, make sure you instantiate all the fields in your copy method!

**Parameters**

- **memo** – A dictionary mapping object identifiers (id(obj)) to their copied instance. Use this to avoid infinite recursion and diverged copies.
- **_memo** (*dict[int, Any]*)

**Return type**
*SimStatePlugin*

**merge**(*others*, *merge_conditions*, *common_ancestor=None*)

Should merge the state plugin with the provided others. This will be called by `state.merge()` after copying the target state, so this should mutate the current instance to merge with the others.

Note that when multiple instances of a single plugin object (for example, a file) are referenced in the state, it is important that merge only ever be called once. This should be solved by designating one of the plugin's referees as the "real owner", who should be the one to actually merge it. This technique doesn't work to resolve the similar issue that arises during copying because merging doesn't produce a new reference to insert.

There will be n `others` and n+1 merge conditions, since the first condition corresponds to self. To match elements up to conditions, say `zip([self] + others, merge_conditions)`

When implementing this, make sure that you "deepen" both `others` and `common_ancestor` before calling sub-elements' merge methods, e.g.

```
self.foo.merge(
    [o.foo for o in others],
    merge_conditions,
    common_ancestor=common_ancestor.foo if common_ancestor is not None else None
)
```

During static analysis, merge_conditions can be None, in which case you should use `state.solver.union(values)`. TODO: fish please make this less bullshit

There is a utility `claripy.ite_cases` which will help with constructing arbitrarily large merged ASTs. Use it like `self.bar = claripy.ite_cases(zip(conditions[1:], [o.bar for o in others]), self.bar)`

**Parameters**

- **others** – the other state plugins to merge with
- **merge_conditions** – a symbolic condition for each of the plugins
- **common_ancestor** – a common ancestor of this plugin and the others being merged

**Returns**
True if the state plugins are actually merged.

**Return type**
bool

**classmethod register_default**(*name*, *xtr=None*)

**Return type**
None

**Parameters**

- **name** (*str*)
- **xtr** (*type[SimStatePlugin] | str | None*)

**init_state**()

Use this function to perform any initialization on the state at plugin-add time

**Return type**
None

class angr.SimulationManager

Bases: object

The Simulation Manager is the future future.

Simulation managers allow you to wrangle multiple states in a slick way. States are organized into "stashes", which you can step forward, filter, merge, and move around as you wish. This allows you to, for example, step two different stashes of states at different rates, then merge them together.

Stashes can be accessed as attributes (i.e. .active). A mulpyplexed stash can be retrieved by prepending the name with *mp_*, e.g. *.mp_active*. A single state from the stash can be retrieved by prepending the name with *one_*, e.g. *.one_active*.

Note that you shouldn't usually be constructing SimulationManagers directly - there is a convenient shortcut for creating them in `Project.factory`: see *angr.factory.AngrObjectFactory*.

The most important methods you should look at are `step`, `explore`, and `use_technique`.

**Parameters**

- **project** (angr.project.Project) – A Project instance.
- **stashes** – A dictionary to use as the stash store.
- **active_states** – Active states to seed the "active" stash with.
- **hierarchy** – A StateHierarchy object to use to track the relationships between states.
- **resilience** – A set of errors to catch during stepping to put a state in the `errore` list. You may also provide the values False, None (default), or True to catch, respectively, no errors, all angr-specific errors, and a set of many common errors.
- **save_unsat** – Set to True in order to introduce unsatisfiable states into the `unsat` stash instead of discarding them immediately.
- **auto_drop** – A set of stash names which should be treated as garbage chutes.
- **completion_mode** – A function describing how multiple exploration techniques with the `complete` hook set will interact. By default, the builtin function `any`.
- **techniques** – A list of techniques that should be pre-set to use with this manager.
- **suggestions** – Whether to automatically install the Suggestions exploration technique. Default True.

**Variables**

- **errored** – Not a stash, but a list of ErrorRecords. Whenever a step raises an exception that we catch, the state and some information about the error are placed in this list. You can adjust the list of caught exceptions with the *resilience* parameter.
- **stashes** – All the stashes on this instance, as a dictionary.
- **completion_mode** – A function describing how multiple exploration techniques with the `complete` hook set will interact. By default, the builtin function `any`.

ALL = '_ALL'

DROP = '_DROP'

__init__(*project*, *active_states=None*, *stashes=None*, *hierarchy=None*, *resilience=None*, *save_unsat=False*, *auto_drop=None*, *errored=None*, *completion_mode=<built-in function any>*, *techniques=None*, *suggestions=True*, ***kwargs*)

**active:** list[*SimState*]

**stashed:** list[*SimState*]

**pruned:** list[*SimState*]

**unsat:** list[*SimState*]

**deadended:** list[*SimState*]

**unconstrained:** list[*SimState*]

**found:** list[*SimState*]

**one_active:** *SimState*

**one_stashed:** *SimState*

**one_pruned:** *SimState*

**one_unsat:** *SimState*

**one_deadended:** *SimState*

**one_unconstrained:** *SimState*

**one_found:** *SimState*

**property errored:** list[*ErrorRecord*]

**property stashes:** defaultdict[str, list[*SimState*]]

**mulpyplex**(**stashes*)

Mulpyplex across several stashes.

**Parameters**
**stashes** – the stashes to mulpyplex

**Returns**
a mulpyplexed list of states from the stashes in question, in the specified order

**copy**(*deep=False*)

Make a copy of this simulation manager. Pass `deep=True` to copy all the states in it as well.

If the current callstack includes hooked methods, the already-called methods will not be included in the copy.

**use_technique**(*tech*)

Use an exploration technique with this SimulationManager.

Techniques can be found in *angr.exploration_techniques*.

**Parameters**
**tech** (ExplorationTechnique) – An ExplorationTechnique object that contains code to modify this SimulationManager's behavior.

**Returns**
The technique that was added, for convenience

**remove_technique**(*tech*)

Remove an exploration technique from a list of active techniques.

**Parameters**
**tech** (ExplorationTechnique) – An ExplorationTechnique object.

**explore**(*stash='active'*, *n=None*, *find=None*, *avoid=None*, *find_stash='found'*, *avoid_stash='avoid'*, *cfg=None*, *num_find=1*, *avoid_priority=False*, ***kwargs*)

Tick stash "stash" forward (up to "n" times or until "num_find" states are found), looking for condition "find", avoiding condition "avoid". Stores found states into "find_stash' and avoided states into "avoid_stash".

The "find" and "avoid" parameters may be any of:

- An address to find
- A set or list of addresses to find
- A function that takes a state and returns whether or not it matches.

If an angr CFG is passed in as the "cfg" parameter and "find" is either a number or a list or a set, then any states which cannot possibly reach a success state without going through a failure state will be preemptively avoided.

**run**(*stash='active'*, *n=None*, *until=None*, ***kwargs*)

Run until the SimulationManager has reached a completed state, according to the current exploration techniques. If no exploration techniques that define a completion state are being used, run until there is nothing left to run.

**Parameters**

- **stash** – Operate on this stash
- **n** – Step at most this many times
- **until** – If provided, should be a function that takes a SimulationManager and returns True or False. Stepping will terminate when it is True.

**Returns**
The simulation manager, for chaining.

**Return type**
*SimulationManager*

**complete**()

Returns whether or not this manager has reached a "completed" state.

**step**(*stash='active'*, *target_stash=None*, *n=None*, *selector_func=None*, *step_func=None*, *error_list=None*, *successor_func=None*, *until=None*, *filter_func=None*, ***run_args*)

Step a stash of states forward and categorize the successors appropriately.

The parameters to this function allow you to control everything about the stepping and categorization process.

**Parameters**

- **stash** – The name of the stash to step (default: 'active')
- **target_stash** – The name of the stash to put the results in (default: same as `stash`)
- **error_list** – The list to put ErrorRecord objects in (default: `self.errored`)
- **selector_func** – If provided, should be a function that takes a state and returns a boolean. If True, the state will be stepped. Otherwise, it will be kept as-is.

- **step_func** – If provided, should be a function that takes a SimulationManager and returns a SimulationManager. Will be called with the SimulationManager at every step. Note that this function should not actually perform any stepping - it is meant to be a maintenance function called after each step.
- **successor_func** – If provided, should be a function that takes a state and return its successors. Otherwise, project.factory.successors will be used.
- **filter_func** – If provided, should be a function that takes a state and return the name of the stash, to which the state should be moved.
- **until** – (DEPRECATED) If provided, should be a function that takes a SimulationManager and returns True or False. Stepping will terminate when it is True.
- **n** – (DEPRECATED) The number of times to step (default: 1 if "until" is not provided)

Additionally, you can pass in any of the following keyword args for project.factory.successors:

**Parameters**

- **jumpkind** – The jumpkind of the previous exit
- **addr** – An address to execute at instead of the state's ip.
- **stmt_whitelist** – A list of stmt indexes to which to confine execution.
- **last_stmt** – A statement index at which to stop execution.
- **thumb** – Whether the block should be lifted in ARM's THUMB mode.
- **backup_state** – A state to read bytes from instead of using project memory.
- **opt_level** – The VEX optimization level to use.
- **insn_bytes** – A string of bytes to use for the block instead of the project.
- **size** – The maximum size of the block, in bytes.
- **num_inst** – The maximum number of instructions.
- **traceflags** – traceflags to be passed to VEX. Default: 0

**Returns**
The simulation manager, for chaining.

**Return type**
*SimulationManager*

**step_state**(*state*, *successor_func=None*, *error_list=None*, ***run_args*)

Don't use this function manually - it is meant to interface with exploration techniques.

**filter**(*state*, *filter_func=None*)

Don't use this function manually - it is meant to interface with exploration techniques.

**selector**(*state*, *selector_func=None*)

Don't use this function manually - it is meant to interface with exploration techniques.

**successors**(*state*, *successor_func=None*, ***run_args*)

Don't use this function manually - it is meant to interface with exploration techniques.

**prune**(*filter_func=None*, *from_stash='active'*, *to_stash='pruned'*)

Prune unsatisfiable states from a stash.

This function will move all unsatisfiable states in the given stash into a different stash.

**Parameters**

- **filter_func** – Only prune states that match this filter.
- **from_stash** – Prune states from this stash. (default: 'active')
- **to_stash** – Put pruned states in this stash. (default: 'pruned')

**Returns**
The simulation manager, for chaining.

**Return type**
*SimulationManager*

**populate**(*stash*, *states*)

Populate a stash with a collection of states.

**Parameters**

- **stash** – A stash to populate.
- **states** – A list of states with which to populate the stash.

**absorb**(*simgr*)

Collect all the states from `simgr` and put them in their corresponding stashes in this manager. This will not modify `simgr`.

**move**(*from_stash*, *to_stash*, *filter_func=None*)

Move states from one stash to another.

**Parameters**

- **from_stash** – Take matching states from this stash.
- **to_stash** – Put matching states into this stash.
- **filter_func** – Stash states that match this filter. Should be a function that takes a state and returns True or False. (default: stash all states)

**Returns**
The simulation manager, for chaining.

**Return type**
*SimulationManager*

**stash**(*filter_func=None*, *from_stash='active'*, *to_stash='stashed'*)

Stash some states. This is an alias for move(), with defaults for the stashes.

**Parameters**

- **filter_func** – Stash states that match this filter. Should be a function that takes a state and returns True or False. (default: stash all states)
- **from_stash** – Take matching states from this stash. (default: 'active')
- **to_stash** – Put matching states into this stash. (default: 'stashed')

**Returns**
The simulation manager, for chaining.

**Return type**
*SimulationManager*

**unstash**(*filter_func=None*, *to_stash='active'*, *from_stash='stashed'*)

Unstash some states. This is an alias for move(), with defaults for the stashes.

**Parameters**

- **filter_func** – Unstash states that match this filter. Should be a function that takes a state and returns True or False. (default: unstash all states)
- **from_stash** – take matching states from this stash. (default: 'stashed')
- **to_stash** – put matching states into this stash. (default: 'active')

**Returns**
The simulation manager, for chaining.

**Return type**
*SimulationManager*

**drop**(*filter_func=None*, *stash='active'*)

Drops states from a stash. This is an alias for move(), with defaults for the stashes.

**Parameters**

- **filter_func** – Drop states that match this filter. Should be a function that takes a state and returns True or False. (default: drop all states)
- **stash** – Drop matching states from this stash. (default: 'active')

**Returns**
The simulation manager, for chaining.

**Return type**
*SimulationManager*

**apply**(*state_func=None*, *stash_func=None*, *stash='active'*, *to_stash=None*)

Applies a given function to a given stash.

**Parameters**

- **state_func** – A function to apply to every state. Should take a state and return a state. The returned state will take the place of the old state. If the function *doesn't* return a state, the old state will be used. If the function returns a list of states, they will replace the original states.
- **stash_func** – A function to apply to the whole stash. Should take a list of states and return a list of states. The resulting list will replace the stash. If both state_func and stash_func are provided state_func is applied first, then stash_func is applied on the results.
- **stash** – A stash to work with.
- **to_stash** – If specified, this stash will be used to store the resulting states instead.

**Returns**
The simulation manager, for chaining.

**Return type**
*SimulationManager*

**split**(*stash_splitter=None*, *stash_ranker=None*, *state_ranker=None*, *limit=8*, *from_stash='active'*, *to_stash='stashed'*)

Split a stash of states into two stashes depending on the specified options.

The stash from_stash will be split into two stashes depending on the other options passed in. If to_stash is provided, the second stash will be written there.

stash_splitter overrides stash_ranker, which in turn overrides state_ranker. If no functions are provided, the states are simply split according to the limit.

The sort done with state_ranker is ascending.

**Parameters**

- **stash_splitter** – A function that should take a list of states and return a tuple of two lists (the two resulting stashes).
- **stash_ranker** – A function that should take a list of states and return a sorted list of states. This list will then be split according to "limit".
- **state_ranker** – An alternative to stash_splitter. States will be sorted with outputs of this function, which are to be used as a key. The first "limit" of them will be kept, the rest split off.
- **limit** – For use with state_ranker. The number of states to keep. Default: 8
- **from_stash** – The stash to split (default: 'active')
- **to_stash** – The stash to write to (default: 'stashed')

**Returns**
The simulation manager, for chaining.

**Return type**
*SimulationManager*

**merge**(*merge_func=None*, *merge_key=None*, *stash='active'*, *prune=True*)

Merge the states in a given stash.

**Parameters**

- **stash** – The stash (default: 'active')
- **merge_func** – If provided, instead of using state.merge, call this function with the states as the argument. Should return the merged state.
- **merge_key** – If provided, should be a function that takes a state and returns a key that will compare equal for all states that are allowed to be merged together, as a first approximation. By default: uses PC, callstack, and open file descriptors.
- **prune** – Whether to prune the stash prior to merging it

**Returns**
The simulation manager, for chaining.

**Return type**
*SimulationManager*

**exception** angr.**SimulationManagerError**

Bases: *AngrError*

**class** angr.**StateHierarchy**

Bases: object

The state hierarchy holds weak references to SimStateHistory objects in a directed acyclic graph. It is useful for queries about a state's ancestry, notably "what is the best ancestor state for a merge among these states" and "what is the most recent unsatisfiable state while using LAZY_SOLVES"

**__init__**()

**get_ref**(*obj*)

**dead_ref**(*ref*)

**defer_cleanup**()

**add_state**(*s*)

**add_history**(*h*)

**simplify**()

**full_simplify**()

**lineage**(*h*)

Returns the lineage of histories leading up to *h*.

**all_successors**(*h*)

**history_successors**(*h*)

**history_predecessors**(*h*)

**history_contains**(*h*)

**unreachable_state**(*state*)

**unreachable_history**(*h*)

**most_mergeable**(*states*)

Find the "most mergeable" set of states from those provided.

**Parameters**
**states** – a list of states

**Returns**
a tuple of: (list of states to merge, those states' common history, list of states to not merge yet)

**exception** angr.**TracerEnvironmentError**

Bases: *AngrError*

**exception** angr.**UnsupportedCCallError**

Bases: *SimCCallError*, *SimUnsupportedError*

**exception** angr.**UnsupportedDirtyError**

Bases: *UnsupportedIRStmtError*, *SimUnsupportedError*

**exception** angr.**UnsupportedIRExprError**

Bases: *SimExpressionError*, *SimUnsupportedError*

**exception** angr.**UnsupportedIROpError**

Bases: *SimOperationError*, *SimUnsupportedError*

**exception** angr.**UnsupportedIRStmtError**

Bases: *SimStatementError*, *SimUnsupportedError*

**exception** angr.**UnsupportedNodeTypeError**

Bases: *AngrError*, NotImplementedError

angr.**UnsupportedSyscallError**

alias of *AngrUnsupportedSyscallError*

angr.**default_cc**(*arch*, *platform='Linux'*, *language=None*, *syscall=False*, *default=None*)

Return the default calling convention for a given architecture, platform, and language combination.

**Parameters**

- **arch** (str) – The architecture name.
- **platform** (str | None) – The platform name (e.g., "Linux" or "Win32").
- **language** (str | None) – The programming language name (e.g., "go").
- **syscall** (bool) – Return syscall convention (True), or normal calling convention (False, default).
- **default** (type[*SimCC*] | None) – The default calling convention to return if nothing fits.

**Return type**

type[*SimCC*] | None

**Returns**

A default calling convention class if we can find one for the architecture, platform, and language combination, or the default if nothing fits.

angr.**load_shellcode**(*shellcode*, *arch*, *start_offset=0*, *load_address=0*, *thumb=False*, ***kwargs*)

Load a new project based on a snippet of assembly or bytecode.

**Parameters**

- **shellcode** (bytes | str) – The data to load, as either a bytestring of instructions or a string of assembly text
- **arch** – The name of the arch to use, or an archinfo class
- **start_offset** – The offset into the data to start analysis (default 0)
- **load_address** – The address to place the data in memory (default 0)
- **thumb** – Whether this is ARM Thumb shellcode

angr.**register_analysis**(*cls*, *name*)

## 10.1 angr.ail_callable

**class** angr.ail_callable.**AILCallable**

Bases: *Callable*

A Callable that uses AILCallState for its states.

**perform_call**(**args*, *prototype=None*)

## 10.2 angr.ailment

**class** angr.ailment.**AILBlockRewriter**

Bases: *AILBlockWalker*[*Expression*, *Statement*, Block]

Walks all statements and expressions of an AIL node, and rebuilds expressions, statements, or blocks if needed.

If you need a pure walker without rebuilding, use AILBlockViewer instead.

**Variables**

- **update_block** – True if the block should be updated in place, False if a new block should be created and returned as the result of walk().
- **replace_phi_stmt** – True if you want _handle_Phi be called and vvars potentially replaced; False otherwise. Default to False because in the most majority cases you do not want vvars in a Phi variable be replaced.

**__init__**(*stmt_handlers=None*, *expr_handlers=None*, *update_block=True*, *replace_phi_stmt=False*)

**Parameters**

- **update_block** (*bool*)
- **replace_phi_stmt** (*bool*)

**class** angr.ailment.**AILBlockViewer**

Bases: *AILBlockWalker*[None, None, None]

Walks all statements and expressions of an AIL node and do nothing.

**class** angr.ailment.**AILBlockWalker**

Bases: Generic[ExprType, StmtType, BlockType]

Walks all statements and expressions of an AIL node and construct arbitrary values based on them.

Note that we lazily initialize self._stmt_handlers and self._expr_handlers when they are accessed. This is to support the existing pattern of updating stmt/expr handlers in-place after creating a block walker, and is slightly slower. Overridding handler methods in a new class is the fastest approach.

**__init__**(*stmt_handlers=None*, *expr_handlers=None*)

**classmethod rebuild_default_handler_funcs**()

**Return type**
None

**property stmt_handlers: dict[type, Callable[[int, Any, Block | None], StmtType]]**

**property expr_handlers: dict[type, Callable[[int, Any, int, *Statement* | None, Block | None], ExprType]]**

**reset**()

Reset per-walk state variables so that this walker can be reused for another walk. Subclasses that updates state across a walk must override this to clear that state.

**Return type**
None

**walk**(*block*)

**Return type**
BlockType

**Parameters**
**block** (Block)

**walk_statement**(*stmt*, *block=None*, *stmt_idx=0*)

**Return type**
StmtType

**Parameters**

- **stmt** (Statement)
- **block** (Block | *None*)
- **stmt_idx** (*int*)

**walk_expression**(*expr*, *stmt_idx=None*, *stmt=None*, *block=None*)

**Return type**
ExprType

**Parameters**

- **expr** (Expression)
- **stmt_idx** (*int* | *None*)
- **stmt** (Statement | *None*)
- **block** (Block | *None*)

**class** angr.ailment.**Assignment**

Bases: object

Marker for Statement instances whose variant is Assignment.

**static __new__**(*cls*, *idx*, *dst*, *src*, ***tags*)

**Return type**
Statement

**class** angr.ailment.**BinaryOp**

Bases: object

Marker for Expression instances whose variant is BinaryOp.

**COMPARISON_NEGATION = {'CmpEQ': 'CmpNE', 'CmpGE': 'CmpLT', 'CmpGT': 'CmpLE', 'CmpLE': 'CmpGT', 'CmpLT': 'CmpGE', 'CmpNE': 'CmpEQ'}**

**static __new__**(*cls*, *idx*, *op*, *operands*, *signed=False*, ** (Keyword-only parameters separator (PEP 3102))*, *bits=None*, *floating_point=False*, *rounding_mode=None*, *vector_count=None*, *vector_size=None*, ***tags*)

**Return type**
Expression

**class** angr.ailment.**Block**

Bases: object

**classmethod __new__**(**args*, ***kwargs*)

**addr**

**clear_hash**()

**copy**(*statements=None*)

**dbg_repr**(*indent=0*)

**deep_copy**(*manager*)

**classmethod from_bytes**(*data*)

Inverse of `to_bytes`.

**idx**

**likes**(*other*)

**original_size**

**pp**()

**sort_key**

**statements**

**to_bytes**()

Postcard-encode the full Block state – `(addr, original_size, idx, statements)`, with statements embedded as their [*AilStatement*] payloads. `cached_hash` is transient and is recomputed after `from_bytes`. Every statement must be an AIL `Statement`; anything else raises `TypeError`.

**class** angr.ailment.**Const**

Bases: `object`

Marker for `Expression` instances whose variant is `Const`.

`Const(idx, value, bits, **tags)` returns an `Expression` – the marker class is not in the instance's MRO.

**static __new__**(*cls*, *idx*, *value*, *bits*, ***tags*)

**Return type**
`Expression`

**class** angr.ailment.**Expression**

Bases: `object`

Marker for `isinstance(x, Expression)` checks.

Real AIL expression instances are `angr.rustylib.ailment.Expression` (a single fat-enum pyclass). The per-variant markers (Const, BinaryOp, …) dispatch on the variant tag via metaclass `__instancecheck__`.

**__init__**(*idx=None*, **_extra*, ***tags*)

**static from_bytes**(*data*)

Deserialize an Expression from bytes.

**Parameters**
**data** (`bytes`)

**class** angr.ailment.**ExpressionKind**

Bases: `object`

Integer tag for `Expression` variants. Exposed as the value of the `kind` getter on the `Expression` pyclass; replaces the prior `&'static str` representation so dispatch lookups become integer hash/compare instead of string interning/hash.

Note: `__hash__` returns `self as u64` so the enum hashes identically to its integer value – a dict keyed by `ExpressionKind` accepts lookups by raw `int` and vice versa.

Array = <ExpressionKind.Array: 21>

BasePointerOffset = <ExpressionKind.BasePointerOffset: 25>

BinaryOp = <ExpressionKind.BinaryOp: 7>

Call = <ExpressionKind.Call: 14>

VEXCCallExpression = <ExpressionKind.VEXCCallExpression: 16>

VirtualVariable = <ExpressionKind.VirtualVariable: 4>

name

value

class angr.ailment.**IRSBConverter**

Bases: *Converter*

**static convert**(*irsb*, *manager*)

Convert the given IRSB to an AIL block

**Parameters**

- **irsb** – The IRSB to convert
- **manager** – The manager to use

**Returns**
Returns the converted block

class angr.ailment.**IRegister**

Bases: object

Marker for `Expression` instances whose variant is `IRegister`: a register addressed through a VEX GetI/PutI register array as `array_base + (((ix + array_bias) % array_nElems) << array_shift)`.

**static __new__**(*cls*, *idx*, *reg_offset*, *bits*, ***, *array_base=0*, *array_bias=0*, *array_nElems=1*, *array_shift=0*, ***tags*)

**Return type**
`Expression`

class angr.ailment.**Manager**

Bases: object

**classmethod __new__**(**args*, ***kwargs*)

**atom_ctr**

Next atom index to hand out (the original used *itertools.count()*).

**block_addr**

**ins_addr**

**next_atom**()

**reset**()

**tyenv**

**variable_map**

Attached by Clinic so that optimization passes, peephole optimizations, and region simplifiers can use VariableMap.

**vex_stmt_idx**

class angr.ailment.**NoOp**

Bases: object

Marker for `Statement` instances whose variant is `NoOp`.

Placeholder for a removed statement; defines and uses no atoms. Primarily used by the AIL simplifier's dead-assignment removal so the indices of surrounding statements stay stable until the block is compacted.

**static __new__**(*cls*, *idx*, ***tags*)

**Return type**
Statement

**class** angr.ailment.**PCodeIRSBConverter**

Bases: *Converter*

Converts a p-code IRSB to an AIL block

**static convert**(*irsb*, *manager*)

Convert the given IRSB to an AIL block

**Parameters**

- **irsb** (*IRSB*) – IRSB to convert
- **manager** (Manager) – Manager to use

**Returns**
Converted block

**__init__**(*irsb*, *manager*)

**Parameters**

- **irsb** (IRSB)
- **manager** (*Manager*)

**class** angr.ailment.**Register**

Bases: object

Marker for Expression instances whose variant is Register.

**static __new__**(*cls*, *idx*, *reg_offset*, *bits*, ***tags*)

**Return type**
Expression

**class** angr.ailment.**Statement**

Bases: object

Marker for isinstance(x, Statement) checks.

**__init__**(*idx=None*, **_extra*, ***tags*)

**static from_bytes**(*data*)

Deserialize a Statement from bytes.

**Parameters**
**data** (bytes)

**class** angr.ailment.**Tmp**

Bases: object

Marker for Expression instances whose variant is Tmp.

**static __new__**(*cls*, *idx*, *tmp_idx*, *bits*, ***tags*)

**Return type**
Expression

class angr.ailment.**UnaryOp**

Bases: object

Marker for Expression instances whose variant is UnaryOp.

static **__new__**(*cls*, *idx*, *op*, *operand*, *bits=None*, *floating_point=False*, ***tags*)

**Return type**
Expression

class angr.ailment.**VEXIRSBConverter**

Bases: object

static **convert**(*irsb*, *manager*)

Fallback: convert a cached pyvex Python *IRSB* object.

static **convert_from_lift**(*arch*, *addr*, *data*, *manager*, ***, *opt_level=1*, *traceflags=0*, *strict_block_end=False*, *collect_data_refs=False*, *load_from_ro_regions=False*, *const_prop=False*, *cross_insn_opt=True*, *max_inst=99*, *max_bytes=None*, *bytes_offset=0*)

Default fast path: lift *data* at *addr* directly into libVEX and convert the resulting C IRSB to an AIL block without materializing a pyvex Python IRSB.

## 10.2.1 angr.ailment.block

Shim for `from angr.ailment.block import Block`.

class angr.ailment.block.**Block**

Bases: object

classmethod **__new__**(**args*, ***kwargs*)

**addr**

**clear_hash**()

**copy**(*statements=None*)

**dbg_repr**(*indent=0*)

**deep_copy**(*manager*)

**classmethod from_bytes**(*data*)

Inverse of `to_bytes`.

**idx**

**likes**(*other*)

**original_size**

**pp**()

**sort_key**

**statements**

**to_bytes**()

Postcard-encode the full Block state – `(addr, original_size, idx, statements)`, with statements embedded as their [*AilStatement*] payloads. `cached_hash` is transient and is recomputed after `from_bytes`. Every statement must be an AIL `Statement`; anything else raises `TypeError`.

### 10.2.2 angr.ailment.block_walker

**class** angr.ailment.block_walker.**AILBlockWalker**

Bases: Generic[ExprType, StmtType, BlockType]

Walks all statements and expressions of an AIL node and construct arbitrary values based on them.

Note that we lazily initialize self._stmt_handlers and self._expr_handlers when they are accessed. This is to support the existing pattern of updating stmt/expr handlers in-place after creating a block walker, and is slightly slower. Overridding handler methods in a new class is the fastest approach.

**__init__**(*stmt_handlers=None*, *expr_handlers=None*)

**classmethod rebuild_default_handler_funcs**()

**Return type**
None

**property stmt_handlers: dict[type, Callable[[int, Any, Block | None], StmtType]]**

**property expr_handlers: dict[type, Callable[[int, Any, int, *Statement* | None, Block | None], ExprType]]**

**reset**()

Reset per-walk state variables so that this walker can be reused for another walk. Subclasses that updates state across a walk must override this to clear that state.

**Return type**
None

**walk**(*block*)

**Return type**
BlockType

**Parameters**
**block** (Block)

**walk_statement**(*stmt*, *block=None*, *stmt_idx=0*)

**Return type**
StmtType

**Parameters**

- **stmt** (Statement)
- **block** (Block | *None*)
- **stmt_idx** (*int*)

**walk_expression**(*expr*, *stmt_idx=None*, *stmt=None*, *block=None*)

**Return type**
ExprType

**Parameters**

- **expr** (Expression)
- **stmt_idx** (*int* | *None*)
- **stmt** (Statement | *None*)
- **block** (Block | *None*)

**class** angr.ailment.block_walker.**AILBlockViewer**

Bases: *AILBlockWalker*[None, None, None]

Walks all statements and expressions of an AIL node and do nothing.

**class** angr.ailment.block_walker.**AILBlockRewriter**

Bases: *AILBlockWalker*[*Expression*, *Statement*, Block]

Walks all statements and expressions of an AIL node, and rebuilds expressions, statements, or blocks if needed.

If you need a pure walker without rebuilding, use AILBlockViewer instead.

**Variables**

- **update_block** – True if the block should be updated in place, False if a new block should be created and returned as the result of walk().
- **replace_phi_stmt** – True if you want _handle_Phi be called and vvars potentially replaced; False otherwise. Default to False because in the most majority cases you do not want vvars in a Phi variable be replaced.

**__init__**(*stmt_handlers=None*, *expr_handlers=None*, *update_block=True*, *replace_phi_stmt=False*)

**Parameters**

- **update_block** (*bool*)
- **replace_phi_stmt** (*bool*)

### 10.2.3 angr.ailment.constant

### 10.2.4 angr.ailment.converter_common

**exception** angr.ailment.converter_common.**SkipConversionNotice**

Bases: Exception

**class** angr.ailment.converter_common.**Converter**

Bases: object

**static convert**(*irsb*, *manager*)

### 10.2.5 angr.ailment.converter_pcode

**class** angr.ailment.converter_pcode.**PCodeIRSBConverter**

Bases: *Converter*

Converts a p-code IRSB to an AIL block

**static convert**(*irsb*, *manager*)

Convert the given IRSB to an AIL block

**Parameters**

- **irsb** (*IRSB*) – IRSB to convert
- **manager** (Manager) – Manager to use

**Returns**
Converted block

**__init__**(*irsb*, *manager*)

**Parameters**

- **irsb** (IRSB)
- **manager** (*Manager*)

### 10.2.6 angr.ailment.converter_vex

**class** angr.ailment.converter_vex.**VEXIRSBConverter**

Bases: object

**static convert**(*irsb*, *manager*)

Fallback: convert a cached pyvex Python *IRSB* object.

**static convert_from_lift**(*arch*, *addr*, *data*, *manager*, ***, *opt_level=1*, *traceflags=0*, *strict_block_end=False*, *collect_data_refs=False*, *load_from_ro_regions=False*, *const_prop=False*, *cross_insn_opt=True*, *max_inst=99*, *max_bytes=None*, *bytes_offset=0*)

Default fast path: lift *data* at *addr* directly into libVEX and convert the resulting C IRSB to an AIL block without materializing a pyvex Python IRSB.

### 10.2.7 angr.ailment.expression

AIL Expression classes.

AIL expression instances are `angr.rustylib.ailment.Expression` – a single Rust pyclass wrapping the `AilExpression` enum. The per-variant classes in this module (`Const`, `BinaryOp`, `Load`, ...) are Python-side *marker* classes:

- Each marker's `__new__` calls one of the `Expression._new_*` factory static methods and returns the resulting `Expression` instance.
- A metaclass on each marker makes `isinstance(x, Const)` work by dispatching on the variant tag (`Expression.kind`). The `_AilMarkerMeta` checks the tag.

- For static type checkers each marker name is aliased to the `Expression` pyclass itself.
- Python-side subclassing of these markers is not supported.

**class** angr.ailment.expression.**ITE**

Bases: object

Marker for `Expression` instances whose variant is `ITE`.

**static __new__**(*cls*, *idx*, *cond*, *iftrue*, *iffalse*, ***tags*)

**Return type**
Expression

**class** angr.ailment.expression.**Array**

Bases: object

Marker for `Expression` instances whose variant is `Array`.

**static __new__**(*cls*, *idx*, *elements*, *bits*, ***tags*)

**Return type**
Expression

**class** angr.ailment.expression.**Atom**

Bases: object

Marker class for `isinstance(x, Atom)` checks.

**class** angr.ailment.expression.**BasePointerOffset**

Bases: object

Marker for `Expression` instances whose variant is `BasePointerOffset`.

`isinstance` also matches `StackBaseOffset` instances to preserve the former subclass relationship.

**static __new__**(*cls*, *idx*, *bits*, *base*, *offset*, ***tags*)

**Return type**
Expression

**class** angr.ailment.expression.**BinaryOp**

Bases: object

Marker for `Expression` instances whose variant is `BinaryOp`.

**COMPARISON_NEGATION = {'CmpEQ': 'CmpNE', 'CmpGE': 'CmpLT', 'CmpGT': 'CmpLE', 'CmpLE': 'CmpGT', 'CmpLT': 'CmpGE', 'CmpNE': 'CmpEQ'}**

**static __new__**(*cls*, *idx*, *op*, *operands*, *signed=False*, ***, *bits=None*, *floating_point=False*, *rounding_mode=None*, *vector_count=None*, *vector_size=None*, ***tags*)

**Return type**
Expression

**class** angr.ailment.expression.**Call**

Bases: object

Marker for `Expression` instances whose variant is `Call`.

`isinstance` also matches `Macro` / `FunctionLikeMacro` instances to preserve the former subclass relationships.

**static __new__**(*cls*, *idx*, *target*, *args=None*, *bits=None*, *arg_vvars=None*, ***tags*)

**Return type**
Expression

**class** angr.ailment.expression.**ComboRegister**

Bases: object

Marker for Expression instances whose variant is ComboRegister.

**static __new__**(*cls*, *idx*, *registers*, ***tags*)

**Return type**
Expression

**class** angr.ailment.expression.**Const**

Bases: object

Marker for Expression instances whose variant is Const.

Const(idx, value, bits, **tags) returns an Expression – the marker class is not in the instance's MRO.

**static __new__**(*cls*, *idx*, *value*, *bits*, ***tags*)

**Return type**
Expression

**class** angr.ailment.expression.**Convert**

Bases: object

Marker for Expression instances whose variant is Convert.

**TYPE_INT = <ConvertType.TYPE_INT: 0>**

**TYPE_FP = <ConvertType.TYPE_FP: 1>**

**static __new__**(*cls*, *idx*, *from_bits*, *to_bits*, *is_signed*, *operand*, *from_type=None*, *to_type=None*, *rounding_mode=None*, *vector_count=None*, ***tags*)

**Return type**
Expression

**class** angr.ailment.expression.**ConvertType**

Bases: object

Mirrors *angr.ailment.expression.ConvertType* (Enum).

**TYPE_FP = <ConvertType.TYPE_FP: 1>**

**TYPE_INT = <ConvertType.TYPE_INT: 0>**

**name**

**value**

**class** angr.ailment.expression.**DirtyExpression**

Bases: object

Marker for Expression instances whose variant is DirtyExpression.

**static __new__**(*cls*, *idx*, *callee*, *operands*, *, *guard=None*, *mfx=None*, *maddr=None*, *msize=None*, *bits*, ***tags*)

**Return type**
Expression

**class** angr.ailment.expression.**Expression**

Bases: object

Marker for `isinstance(x, Expression)` checks.

Real AIL expression instances are `angr.rustylib.ailment.Expression` (a single fat-enum pyclass). The per-variant markers (Const, BinaryOp, ...) dispatch on the variant tag via metaclass `__instancecheck__`.

**__init__**(*idx=None*, **_extra*, ***tags*)

**static from_bytes**(*data*)

Deserialize an Expression from bytes.

**Parameters**
**data** (bytes)

**class** angr.ailment.expression.**Extract**

Bases: object

Marker for `Expression` instances whose variant is `Extract`.

**static __new__**(*cls*, *idx*, *bits*, *base*, *offset*, *endness*, ***tags*)

**Return type**
Expression

**class** angr.ailment.expression.**FunctionLikeMacro**

Bases: object

Marker for `Expression` instances whose variant is `FunctionLikeMacro`.

**static __new__**(*cls*, *idx*, *name*, *args*, *bits=None*, *delimiter='()'*, ***tags*)

**Return type**
Expression

**class** angr.ailment.expression.**IRegister**

Bases: object

Marker for `Expression` instances whose variant is `IRegister`: a register addressed through a VEX GetI/PutI register array as `array_base + (((ix + array_bias) % array_nElems) << array_shift)`.

**static __new__**(*cls*, *idx*, *reg_offset*, *bits*, *, *array_base=0*, *array_bias=0*, *array_nElems=1*, *array_shift=0*, ***tags*)

**Return type**
Expression

**class** angr.ailment.expression.**Insert**

Bases: object

Marker for `Expression` instances whose variant is `Insert`.

**static __new__**(*cls*, *idx*, *base*, *offset*, *value*, *endness*, ***tags*)

**Return type**
Expression

**class** angr.ailment.expression.**Let**

Bases: object

Marker for Expression instances whose variant is Let.

**static __new__**(*cls*, *idx*, *defs*, *src*, ***tags*)

**Return type**
Expression

**class** angr.ailment.expression.**Load**

Bases: object

Marker for Expression instances whose variant is Load.

**static __new__**(*cls*, *idx*, *addr*, *size*, *endness*, *, *guard=None*, *alt=None*, ***tags*)

**Return type**
Expression

**class** angr.ailment.expression.**Macro**

Bases: object

Marker for Expression instances whose variant is Macro (abstract).

Also matches FunctionLikeMacro instances to preserve the isinstance(x, Macro) -> True relationship of the former class hierarchy.

**static __new__**(*cls*, *idx*, *name*, *delimiter='()'*, ***tags*)

**Return type**
Expression

**class** angr.ailment.expression.**MultiStatementExpression**

Bases: object

Marker for Expression instances whose variant is MultiStatementExpression.

**static __new__**(*cls*, *idx*, *stmts*, *expr*, ***tags*)

**Return type**
Expression

**class** angr.ailment.expression.**Op**

Bases: object

Marker for isinstance(x, Op) checks.

**class** angr.ailment.expression.**Phi**

Bases: object

Marker for Expression instances whose variant is Phi.

**static __new__**(*cls*, *idx*, *bits*, *src_and_vvars*, ***tags*)

**Return type**
Expression

class angr.ailment.expression.**Register**

Bases: object

Marker for Expression instances whose variant is Register.

static **__new__**(*cls*, *idx*, *reg_offset*, *bits*, ***tags*)

**Return type**
Expression

class angr.ailment.expression.**Reinterpret**

Bases: object

Marker for Expression instances whose variant is Reinterpret.

static **__new__**(*cls*, *idx*, *from_bits*, *from_type*, *to_bits*, *to_type*, *operand*, ***tags*)

**Return type**
Expression

class angr.ailment.expression.**RustEnum**

Bases: object

Marker for Expression instances whose variant is RustEnum.

static **__new__**(*cls*, *idx*, *name*, *fields*, *bits*, ***tags*)

**Return type**
Expression

class angr.ailment.expression.**StackBaseOffset**

Bases: object

Marker for Expression instances whose variant is StackBaseOffset.

static **__new__**(*cls*, *idx*, *bits*, *offset*, ***tags*)

**Return type**
Expression

class angr.ailment.expression.**StringLiteral**

Bases: object

Marker for Expression instances whose variant is StringLiteral.

static **__new__**(*cls*, *idx*, *data*, *bits*, ***tags*)

**Return type**
Expression

class angr.ailment.expression.**Struct**

Bases: object

Marker for Expression instances whose variant is Struct.

static **__new__**(*cls*, *idx*, *name*, *fields*, *field_offsets*, *bits*, ***tags*)

**Return type**
Expression

class angr.ailment.expression.**Tmp**

Bases: object

Marker for Expression instances whose variant is Tmp.

**static __new__**(*cls*, *idx*, *tmp_idx*, *bits*, ***tags*)

**Return type**
Expression

class angr.ailment.expression.**UnaryOp**

Bases: object

Marker for Expression instances whose variant is UnaryOp.

**static __new__**(*cls*, *idx*, *op*, *operand*, *bits=None*, *floating_point=False*, ***tags*)

**Return type**
Expression

class angr.ailment.expression.**VEXCCallExpression**

Bases: object

Marker for Expression instances whose variant is VEXCCallExpression.

**static __new__**(*cls*, *idx*, *callee*, *operands*, *bits*, ***tags*)

**Return type**
Expression

class angr.ailment.expression.**VirtualVariable**

Bases: object

Marker for Expression instances whose variant is VirtualVariable.

**static __new__**(*cls*, *idx*, *varid*, *bits*, *category*, *oident=None*, *reg_vvars=None*, ***tags*)

**Return type**
Expression

class angr.ailment.expression.**VirtualVariableCategory**

Bases: object

Mirrors *angr.ailment.expression.VirtualVariableCategory* (IntEnum).

**COMBO_REGISTER = <VirtualVariableCategory.COMBO_REGISTER: 5>**

**MEMORY = <VirtualVariableCategory.MEMORY: 2>**

**PARAMETER = <VirtualVariableCategory.PARAMETER: 3>**

**REGISTER = <VirtualVariableCategory.REGISTER: 0>**

**STACK = <VirtualVariableCategory.STACK: 1>**

**TMP = <VirtualVariableCategory.TMP: 4>**

**UNKNOWN = <VirtualVariableCategory.UNKNOWN: 6>**

**name**

**value**

angr.ailment.expression.**negate**(*expr*, *manager*)

Negate a comparison or boolean expression.

**Return type**
*Expression*

**Parameters**
**expr** (Expression)

### 10.2.8 angr.ailment.manager

**class** angr.ailment.manager.**Manager**

Bases: object

**classmethod __new__**(**args*, ***kwargs*)

**atom_ctr**

Next atom index to hand out (the original used *itertools.count()*).

**block_addr**

**ins_addr**

**next_atom**()

**reset**()

**tyenv**

**variable_map**

Attached by Clinic so that optimization passes, peephole optimizations, and region simplifiers can use VariableMap.

**vex_stmt_idx**

### 10.2.9 angr.ailment.statement

AIL Statement classes.

Mirror of angr.ailment.expression for the Statement side.

**class** angr.ailment.statement.**CAS**

Bases: object

Marker for Statement instances whose variant is CAS.

**static __new__**(*cls*, *idx*, *addr*, *data_lo*, *data_hi*, *expd_lo*, *expd_hi*, *old_lo*, *old_hi*, *endness*, ***tags*)

**Return type**
Statement

**class** angr.ailment.statement.**Assignment**

Bases: object

Marker for Statement instances whose variant is Assignment.

**static __new__**(*cls*, *idx*, *dst*, *src*, ***tags*)

**Return type**
Statement

class angr.ailment.statement.**ConditionalJump**

Bases: object

Marker for Statement instances whose variant is ConditionalJump.

static **__new__**(*cls*, *idx*, *condition*, *true_target*, *false_target*, *, *true_target_idx=0*, *false_target_idx=0*, ***tags*)

**Return type**
Statement

class angr.ailment.statement.**DirtyStatement**

Bases: object

Marker for Statement instances whose variant is DirtyStatement.

static **__new__**(*cls*, *idx*, *dirty*, ***tags*)

**Return type**
Statement

class angr.ailment.statement.**Jump**

Bases: object

Marker for Statement instances whose variant is Jump.

static **__new__**(*cls*, *idx*, *target*, *target_idx=0*, ***tags*)

**Return type**
Statement

class angr.ailment.statement.**Label**

Bases: object

Marker for Statement instances whose variant is Label.

static **__new__**(*cls*, *idx*, *name*, ***tags*)

**Return type**
Statement

class angr.ailment.statement.**NoOp**

Bases: object

Marker for Statement instances whose variant is NoOp.

Placeholder for a removed statement; defines and uses no atoms. Primarily used by the AIL simplifier's dead-assignment removal so the indices of surrounding statements stay stable until the block is compacted.

static **__new__**(*cls*, *idx*, ***tags*)

**Return type**
Statement

class angr.ailment.statement.**Return**

Bases: object

Marker for Statement instances whose variant is Return.

static **__new__**(*cls*, *idx*, *ret_exprs*, ***tags*)

**Return type**
Statement

class angr.ailment.statement.**SideEffectStatement**

Bases: object

Marker for Statement instances whose variant is SideEffectStatement.

static **__new__**(*cls*, *idx*, *expr*, *ret_expr=None*, *fp_ret_expr=None*, ***tags*)

**Return type**
Statement

class angr.ailment.statement.**Statement**

Bases: object

Marker for isinstance(x, Statement) checks.

**__init__**(*idx=None*, **_extra*, ***tags*)

static **from_bytes**(*data*)

Deserialize a Statement from bytes.

**Parameters**
**data** (bytes)

class angr.ailment.statement.**Store**

Bases: object

Marker for Statement instances whose variant is Store.

static **__new__**(*cls*, *idx*, *addr*, *data*, *size*, *endness*, *guard=None*, ***tags*)

**Return type**
Statement

class angr.ailment.statement.**TaggedObject**

Bases: object

Marker class for backward-compatible isinstance(x, TaggedObject) checks.

The real hierarchy has no shared base anymore; this class only exists so legacy isinstance checks keep returning the same result.

Some legacy code does __hash__ = ailment.statement.TaggedObject.__hash__ to opt in to the cached-hash machinery. We expose a pure-Python __hash__ here so that idiom keeps working.

class angr.ailment.statement.**WeakAssignment**

Bases: object

Marker for Statement instances whose variant is WeakAssignment.

static **__new__**(*cls*, *idx*, *dst*, *src*, ***tags*)

**Return type**
Statement

### 10.2.10 angr.ailment.tagged_object

Python-side marker for the legacy isinstance(x, TaggedObject) checks.

We can get rid of this base class once IncompleteSwitchCaseHeadStatement is migrated to Rust.

class angr.ailment.tagged_object.**TagDict**

Bases: TypedDict

Schema for the `.tags` mapping on AIL data classes.

Only primitive-valued tags survive the Rust port. `reg_vvars` was promoted to a dedicated field on `VirtualVariable`. Variable information (`variable`, `variable_offset`, `reference_*`) now lives in a side `VariableMap` (see `angr.analyses.decompiler.variable_map`).

**always_propagate:** NotRequired[bool]

**block_idx:** NotRequired[int]

**deref_src_addr:** NotRequired[int]

**extra_def:** NotRequired[bool]

**extra_defs:** NotRequired[list[int]]

**ins_addr:** NotRequired[int]

**is_prototype_guessed:** NotRequired[bool]

**keep_in_slice:** NotRequired[bool]

**orig_ins_addr:** NotRequired[int]

**reg_name:** NotRequired[str]

**uninitialized:** NotRequired[bool]

**vex_block_addr:** NotRequired[int]

**vex_stmt_idx:** NotRequired[int]

**write_size:** NotRequired[int]

class angr.ailment.tagged_object.**TaggedObject**

Bases: object

Marker class for backward-compatible `isinstance(x, TaggedObject)` checks.

The real hierarchy has no shared base anymore; this class only exists so legacy isinstance checks keep returning the same result.

Some legacy code does `__hash__ = ailment.statement.TaggedObject.__hash__` to opt in to the cached-hash machinery. We expose a pure-Python `__hash__` here so that idiom keeps working.

**idx:** int

**tags:** Any

### 10.2.11 angr.ailment.utils

type angr.ailment.utils.**GetBitsTypeParams** = *ailment.expression.Expression*

angr.ailment.utils.**get_bits**(*expr*)

**Return type**
int

**Parameters**
**expr** (GetBitsTypeParams)

angr.ailment.utils.**is_none_or_likeable**(*arg1*, *arg2*, *is_list=False*)

Returns whether two things are both None or can like each other

angr.ailment.utils.**is_none_or_matchable**(*arg1*, *arg2*, *is_list=False*)

Returns whether two things are both None or can match each other

angr.ailment.utils.**is_lsb_extract**(*expr*)

Return `True` if `expr` is an `Extract` that takes the least-significant `expr.bits` bits of its base, considering endianness.

**Return type**
bool

**Parameters**
**expr** (Expression)

angr.ailment.utils.**is_lsb_overwrite**(*expr*)

Return `True` if `expr` is an `Insert` that overwrites the least-significant `expr.value.bits` bits of its base, considering endianness.

`Insert` counterpart of `is_lsb_extract`.

**Return type**
bool

**Parameters**
**expr** (Expression)

## 10.3 angr.analyses

**class** angr.analyses.**CDG**

Bases: *Analysis*

Implements a control dependence graph.

**__init__**(*cfg*, *start=None*, *no_construct=False*)

Constructor.

**Parameters**

- **cfg** – The control flow graph upon which this control dependence graph will build
- **start** – The starting point to begin constructing the control dependence graph
- **no_construct** – Skip the construction step. Only used in unit-testing.

**property graph**

**get_post_dominators**()

Return the post-dom tree

**get_dependants**(*run*)

Return a list of nodes that are control dependent on the given node in the control dependence graph

**get_guardians**(*run*)

Return a list of nodes on whom the specific node is control dependent in the control dependence graph

**class** angr.analyses.**CFG**

Bases: *CFGFast*

tl;dr: CFG is just a wrapper around CFGFast for compatibility issues. It will be fully replaced by CFGFast in future releases. Feel free to use CFG if you intend to use CFGFast. Please use CFGEmulated if you *have to* use the old, slow, dynamically-generated version of CFG.

For multiple historical reasons, angr's CFG is accurate but slow, which does not meet what most people expect. We developed CFGFast for light-speed CFG recovery, and renamed the old CFG class to CFGEmulated. For compatibility concerns, CFG was kept as an alias to CFGEmulated.

However, so many new users of angr would load up a binary and generate a CFG immediately after running "pip install angr", and draw the conclusion that "angr's CFG is so slow - angr must be unusable!" Therefore, we made the hard decision: CFG will be an alias to CFGFast, instead of CFGEmulated.

To ease the transition of your existing code and script, the following changes are made:

- A CFG class, which is a sub class of CFGFast, is created.
- You will see both a warning message printed out to stderr and an exception raised by angr if you are passing CFG any parameter that only CFGEmulated supports. This exception is not a sub class of AngrError, so you wouldn't capture it with your old code by mistake.
- In the near future, this wrapper class will be removed completely, and CFG will be a simple alias to CFGFast.

We expect most interfaces are the same between CFGFast and CFGEmulated. Apparently some functionalities (like context-sensitivity, and state keeping) only exist in CFGEmulated, which is when you want to use CFGEmulated instead.

**class** angr.analyses.**DDG**

Bases: *Analysis*

This is a fast data dependence graph directly generated from our CFG analysis result. The only reason for its existence is the speed. There is zero guarantee for being sound or accurate. You are supposed to use it only when you want to track the simplest data dependence, and you do not care about soundness or accuracy.

For a better data dependence graph, please consider performing a better static analysis first (like Value-set Analysis), and then construct a dependence graph on top of the analysis result (for example, the VFG in angr).

The DDG is based on a CFG, which should ideally be a CFGEmulated generated with the following options:

- keep_state=True to keep all input states
- state_add_options=angr.options.refs to store memory, register, and temporary value accesses

You may want to consider a high value for context_sensitivity_level as well when generating the CFG.

Also note that since we are using states from CFG, any improvement in analysis performed on CFG (like a points-to analysis) will directly benefit the DDG.

**__init__**(*cfg*, *start=None*, *call_depth=None*, *block_addrs=None*)

**Parameters**

- **cfg** – Control flow graph. Please make sure each node has an associated *state* with it, e.g. by passing the keep_state=True and state_add_options=angr.options.refs arguments to CFGEmulated.
- **start** – An address, Specifies where we start the generation of this data dependence graph.
- **call_depth** – None or integers. A non-negative integer specifies how deep we would like to track in the call tree. None disables call_depth limit.

- **block_addrs** (*iterable or None*) – A collection of block addresses that the DDG analysis should be performed on.

**property graph**

A networkx DiGraph instance representing the dependence relations between statements. :rtype: networkx.DiGraph

**Type**
returns

**property data_graph**

Get the data dependence graph.

**Returns**
A networkx DiGraph instance representing data dependence.

**Return type**
networkx.DiGraph

**property simplified_data_graph**

return:

**property ast_graph**

**pp()**

Pretty printing.

**dbg_repr()**

Representation for debugging.

**get_predecessors**(*code_location*)

Returns all predecessors of the code location.

**Parameters**
**code_location** – A CodeLocation instance.

**Returns**
A list of all predecessors.

**function_dependency_graph**(*func*)

Get a dependency graph for the function *func*.

**Parameters**
**func** – The Function object in CFG.function_manager.

**Returns**
A networkx.DiGraph instance.

**data_sub_graph**(*pv*, *simplified=True*, *killing_edges=False*, *excluding_types=None*)

Get a subgraph from the data graph or the simplified data graph that starts from node pv.

**Parameters**

- **pv** (ProgramVariable) – The starting point of the subgraph.
- **simplified** (*bool*) – When True, the simplified data graph is used, otherwise the data graph is used.
- **killing_edges** (*bool*) – Are killing edges included or not.
- **excluding_types** (*iterable*) – Excluding edges whose types are among those excluded types.

**Returns**
A subgraph.

**Return type**
networkx.MultiDiGraph

**find_definitions**(*variable*, *location=None*, *simplified_graph=True*)

Find all definitions of the given variable.

**Parameters**

- **variable** (SimVariable)
- **simplified_graph** (*bool*) – True if you just want to search in the simplified graph instead of the normal graph. Usually the simplified graph suffices for finding definitions of register or memory variables.

**Returns**
A collection of all variable definitions to the specific variable.

**Return type**
list

**find_consumers**(*var_def*, *simplified_graph=True*)

Find all consumers to the specified variable definition.

**Parameters**

- **var_def** (ProgramVariable) – The variable definition.
- **simplified_graph** (*bool*) – True if we want to search in the simplified graph, False otherwise.

**Returns**
A collection of all consumers to the specified variable definition.

**Return type**
list

**find_killers**(*var_def*, *simplified_graph=True*)

Find all killers to the specified variable definition.

**Parameters**

- **var_def** (ProgramVariable) – The variable definition.
- **simplified_graph** (*bool*) – True if we want to search in the simplified graph, False otherwise.

**Returns**
A collection of all killers to the specified variable definition.

**Return type**
list

**find_sources**(*var_def*, *simplified_graph=True*)

Find all sources to the specified variable definition.

**Parameters**

- **var_def** (ProgramVariable) – The variable definition.
- **simplified_graph** (*bool*) – True if we want to search in the simplified graph, False otherwise.

**Returns**
A collection of all sources to the specified variable definition.

**Return type**
list

**class** angr.analyses.**VFG**

Bases: *ForwardAnalysis*[*SimState*, *VFGNode*, *VFGJob*, *BlockID*, *SimState*], *Analysis*

This class represents a control-flow graph with static analysis result.

Perform abstract interpretation analysis starting from the given function address. The output is an invariant at the beginning (or the end) of each basic block.

Steps:

- Generate a CFG first if CFG is not provided.
- Identify all merge points (denote the set of merge points as Pw) in the CFG.
- Cut those loop back edges (can be derived from Pw) so that we gain an acyclic CFG.
- **Identify all variables that are 1) from memory loading 2) from initial values, or 3) phi functions. Denote**
  the set of those variables as S_{var}.
- **Start real AI analysis and try to compute a fix point of each merge point. Perform widening/narrowing only on**
  variables in S_{var}.

**__init__**(*cfg=None*, *context_sensitivity_level=2*, *start=None*, *function_start=None*, *interfunction_level=0*, *initial_state=None*, *avoid_runs=None*, *remove_options=None*, *timeout=None*, *max_iterations_before_widening=8*, *max_iterations=40*, *widening_interval=3*, *final_state_callback=None*, *status_callback=None*, *record_function_final_states=False*)

**Parameters**

- **cfg** (*CFGEmulated* | None) – The control-flow graph to base this analysis on. If none is provided, we will construct a CFGEmulated.
- **context_sensitivity_level** (int) – The level of context-sensitivity of this VFG. It ranges from 0 to infinity. Default 2.
- **function_start** (int | None) – The address of the function to analyze.
- **interfunction_level** (int) – The level of interfunction-ness to be
- **initial_state** (*SimState* | None) – A state to use as the initial one
- **avoid_runs** (list[int] | None) – A list of runs to avoid
- **remove_options** (set[str] | None) – State options to remove from the initial state. It only works when *initial_state* is None
- **timeout** (int | None)
- **final_state_callback** (Callable[[*SimState*, *CallStack*], Any] | None) – callback function when countering final state
- **status_callback** (Callable[[*VFG*], Any] | None) – callback function used in _analysis_core_baremetal
- **start** (*int* | *None*)
- **max_iterations_before_widening** (*int*)

- **max_iterations** (*int*)
- **widening_interval** (*int*)
- **record_function_final_states** (*bool*)

**Return type**
None

**property function_initial_states**

**property function_final_states**

**get_any_node**(*addr*)

Get any VFG node corresponding to the basic block at @addr. Note that depending on the context sensitivity level, there might be multiple nodes corresponding to different contexts. This function will return the first one it encounters, which might not be what you want.

**Return type**
*VFGNode* | None

**Parameters**
**addr** (*int*)

**get_all_nodes**(*addr*)

**Return type**
Generator[*VFGNode*]

**irsb_from_node**(*node*)

**copy**()

**MAX_NARROWING_ROUNDS = 2**

**class** angr.analyses.**VSA_DDG**

Bases: *Analysis*

A Data dependency graph based on VSA states. That means we don't (and shouldn't) expect any symbolic expressions.

**__init__**(*vfg=None*, *start_addr=None*, *interfunction_level=0*, *context_sensitivity_level=2*, *keep_data=False*)

Constructor.

**Parameters**

- **vfg** – An already constructed VFG. If not specified, a new VFG will be created with other specified parameters. *vfg* and *start_addr* cannot both be unspecified.
- **start_addr** – The address where to start the analysis (typically, a function's entry point).
- **interfunction_level** – See VFG analysis.
- **context_sensitivity_level** – See VFG analysis.
- **keep_data** – Whether we keep set of addresses as edges in the graph, or just the cardinality of the sets, which can be used as a "weight".

**get_predecessors**(*code_location*)

Returns all predecessors of *code_location*.

**Parameters**
**code_location** – A CodeLocation instance.

**Returns**
A list of all predecessors.

**get_all_nodes**(*simrun_addr*, *stmt_idx*)

Get all DDG nodes matching the given basic block address and statement index.

class angr.analyses.**AnalysesHub**

Bases: *PluginVendor*[Any]

This class contains functions for all the registered and runnable analyses,

**__init__**(*project*)

class angr.analyses.**Analysis**

Bases: object

This class represents an analysis on the program.

**Variables**

- **project** (*Project*) – The project for this analysis.
- **kb** (KnowledgeBase) – The knowledgebase object.
- **_progress_callback** (Callable | None) – A callback function for receiving the progress of this analysis. It only takes one argument, which is a float number from 0.0 to 100.0 indicating the current progress.
- **_show_progressbar** (*bool*) – If a progressbar should be shown during the analysis. It's independent from _progress_callback.
- **_progressbar** (*progress.Progress*) – The progress bar object.

**project:** *Project*

**kb:** *KnowledgeBase*

**errors:** list[*AnalysisLogEntry*] = []

**named_errors:** defaultdict[str, list[*AnalysisLogEntry*]] = {}

**log:** list

**property ram_usage:** float

Return the current RAM usage of the Python process, in bytes. The value is updated at most once per second.

class angr.analyses.**BackwardSlice**

Bases: *Analysis*

Represents a backward slice of the program.

**__init__**(*cfg*, *cdg*, *ddg*, *targets=None*, *cfg_node=None*, *stmt_id=None*, *control_flow_slice=False*, *same_function=False*, *no_construct=False*)

Create a backward slice from a specific statement based on provided control flow graph (CFG), control dependence graph (CDG), and data dependence graph (DDG).

The data dependence graph can be either CFG-based, or Value-set analysis based. A CFG-based DDG is much faster to generate, but it only reflects those states while generating the CFG, and it is neither sound nor accurate. The VSA based DDG (called VSA_DDG) is based on static analysis, which gives you a much better result.

**Parameters**

- **cfg** – The control flow graph.
- **cdg** – The control dependence graph.
- **ddg** – The data dependence graph.
- **targets** – A list of "target" that specify targets of the backward slices. Each target can be a tuple in form of (cfg_node, stmt_idx), or a CodeLocation instance.
- **cfg_node** – Deprecated. The target CFGNode to reach. It should exist in the CFG.
- **stmt_id** – Deprecated. The target statement to reach.
- **control_flow_slice** – True/False, indicates whether we should slice only based on CFG. Sometimes when acquiring DDG is difficult or impossible, you can just create a slice on your CFG. Well, if you don't even have a CFG, then…
- **no_construct** – Only used for testing and debugging to easily create a BackwardSlice object.

**dbg_repr**(*max_display=10*)

Debugging output of this slice.

**Parameters**
**max_display** – The maximum number of SimRun slices to show.

**Returns**
A string representation.

**dbg_repr_run**(*run_addr*)

Debugging output of a single SimRun slice.

**Parameters**
**run_addr** – Address of the SimRun.

**Returns**
A string representation.

**annotated_cfg**(*start_point=None*)

Returns an AnnotatedCFG based on slicing result.

**is_taint_related_to_ip**(*simrun_addr*, *stmt_idx*, *taint_type*, *simrun_whitelist=None*)

Query in taint graph to check if a specific taint will taint the IP in the future or not. The taint is specified with the tuple (simrun_addr, stmt_idx, taint_type).

**Parameters**

- **simrun_addr** – Address of the SimRun.
- **stmt_idx** – Statement ID.
- **taint_type** – Type of the taint, might be one of the following: 'reg', 'tmp', 'mem'.
- **simrun_whitelist** – A list of SimRun addresses that are whitelisted, i.e. the tainted exit will be ignored if it is in those SimRuns.

**Returns**
True/False

**is_taint_impacting_stack_pointers**(*simrun_addr*, *stmt_idx*, *taint_type*, *simrun_whitelist=None*)

Query in taint graph to check if a specific taint will taint the stack pointer in the future or not. The taint is specified with the tuple (simrun_addr, stmt_idx, taint_type).

**Parameters**

- **simrun_addr** – Address of the SimRun.
- **stmt_idx** – Statement ID.
- **taint_type** – Type of the taint, might be one of the following: 'reg', 'tmp', 'mem'.
- **simrun_whitelist** – A list of SimRun addresses that are whitelisted.

**Returns**
True/False.

class angr.analyses.**BinDiff**

Bases: *Analysis*

This class computes the a diff between two binaries represented by angr Projects

**__init__**(*other_project*, *cfg_a=None*, *cfg_b=None*)

**Parameters**
**other_project** – The second project to diff

**functions_probably_identical**(*func_a_addr*, *func_b_addr*, *check_consts=False*)

Compare two functions and return True if they appear identical.

**Parameters**

- **func_a_addr** – The address of the first function (in the first binary).
- **func_b_addr** – The address of the second function (in the second binary).

**Returns**
Whether or not the functions appear to be identical.

**property identical_functions**

A list of function matches that appear to be identical

**Type**
returns

**property differing_functions**

A list of function matches that appear to differ

**Type**
returns

**differing_functions_with_consts**()

**Returns**
A list of function matches that appear to differ including just by constants

**property differing_blocks**

A list of block matches that appear to differ

**Type**
returns

**property identical_blocks**

return A list of all block matches that appear to be identical

**property blocks_with_differing_constants**

A dict of block matches with differing constants to the tuple of constants

**Type**
return

property unmatched_functions

get_function_diff(*function_addr_a*, *function_addr_b*)

**Parameters**

- **function_addr_a** – The address of the first function (in the first binary)
- **function_addr_b** – The address of the second function (in the second binary)

**Returns**
the FunctionDiff of the two functions

class angr.analyses.**BinaryOptimizer**

Bases: *Analysis*

This is a collection of binary optimization techniques we used in Mechanical Phish during the finals of Cyber Grand Challenge. It focuses on dealing with some serious speed-impacting code constructs, and *sort of* worked on *some* CGC binaries compiled with O0. Use this analysis as a reference of how to use data dependency graph and such.

There is no guarantee that BinaryOptimizer will ever work on non-CGC binaries. Feel free to give us PR or MR, but please *do not* ask for support of non-CGC binaries.

BLOCKS_THRESHOLD = 500

__init__(*cfg*, *techniques*)

**Parameters**
**techniques** (*set[str]*)

optimize()

class angr.analyses.**BoyScout**

Bases: *Analysis*

Try to determine the architecture and endieness of a binary blob

__init__(*cookiesize=1*)

class angr.analyses.**CFGArchOptions**

Bases: object

Stores architecture-specific options and settings, as well as the detailed explanation of those options and settings.

Suppose *ao* is the CFGArchOptions object, and there is an option called *ret_jumpkind_heuristics*, you can access it by *ao.ret_jumpkind_heuristics* and set its value via *ao.ret_jumpkind_heuristics = True*

**Variables**

- **OPTIONS** (*dict*) – A dict of all default options for different architectures.
- **arch** (*archinfo.Arch*) – The architecture object.
- **_options** (*dict*) – Values of all CFG options that are specific to the current architecture.

```
OPTIONS = {'ARMCortexM': {'has_arm_code': (<class 'bool'>, False),
'pattern_match_ifuncs': (<class 'bool'>, True), 'ret_jumpkind_heuristics': (<class
'bool'>, True), 'switch_mode_on_nodecode': (<class 'bool'>, False)}, 'ARMEL':
{'has_arm_code': (<class 'bool'>, True), 'pattern_match_ifuncs': (<class 'bool'>,
True), 'ret_jumpkind_heuristics': (<class 'bool'>, True),
'switch_mode_on_nodecode': (<class 'bool'>, True)}, 'ARMHF': {'has_arm_code':
(<class 'bool'>, True), 'pattern_match_ifuncs': (<class 'bool'>, True),
'ret_jumpkind_heuristics': (<class 'bool'>, True), 'switch_mode_on_nodecode':
(<class 'bool'>, True)}}
```

__init__(*arch*, ***options*)

Constructor.

**Parameters**

- **arch** (*archinfo.Arch*) – The architecture instance.
- **options** (*dict*) – Architecture-specific options, which will be used to initialize this object.

arch = None

class angr.analyses.**CFGEmulated**

Bases: *ForwardAnalysis*, *CFGBase*

This class represents a control-flow graph.

tag: str = 'CFGEmulated'

addr_type: Literal['int', 'block_id', 'soot'] = 'block_id'

__init__(*context_sensitivity_level=1*, *start=None*, *avoid_runs=None*, *enable_function_hints=False*, *call_depth=None*, *call_tracing_filter=None*, *initial_state=None*, *starts=None*, *keep_state=False*, *indirect_jump_target_limit=100000*, *resolve_indirect_jumps=True*, *enable_advanced_backward_slicing=False*, *enable_symbolic_back_traversal=False*, *indirect_jump_resolvers=None*, *additional_edges=None*, *no_construct=False*, *normalize=False*, *max_iterations=1*, *address_whitelist=None*, *base_graph=None*, *iropt_level=None*, *max_steps=None*, *state_add_options=None*, *state_remove_options=None*, *model=None*)

All parameters are optional.

**Parameters**

- **context_sensitivity_level** – The level of context-sensitivity of this CFG (see documentation for further details). It ranges from 0 to infinity. Default 1.
- **avoid_runs** – A list of runs to avoid.
- **enable_function_hints** – Whether to use function hints (constants that might be used as exit targets) or not.
- **call_depth** – How deep in the call stack to trace.
- **call_tracing_filter** – Filter to apply on a given path and jumpkind to determine if it should be skipped when call_depth is reached.
- **initial_state** – An initial state to use to begin analysis.
- **starts** (*iterable*) – A collection of starting points to begin analysis. It can contain the following three different types of entries: an address specified as an integer, a 2-tuple that includes an integer address and a jumpkind, or a SimState instance. Unsupported entries in starts will lead to an AngrCFGError being raised.
- **keep_state** – Whether to keep the SimStates for each CFGNode.
- **resolve_indirect_jumps** – Whether to enable the indirect jump resolvers for resolving indirect jumps
- **enable_advanced_backward_slicing** – Whether to enable an intensive technique for resolving indirect jumps
- **enable_symbolic_back_traversal** – Whether to enable an intensive technique for resolving indirect jumps

- **indirect_jump_resolvers** (*list*) – A custom list of indirect jump resolvers. If this list is None or empty, default indirect jump resolvers specific to this architecture and binary types will be loaded.
- **additional_edges** – A dict mapping addresses of basic blocks to addresses of successors to manually include and analyze forward from.
- **no_construct** (*bool*) – Skip the construction procedure. Only used in unit-testing.
- **normalize** (*bool*) – If the CFG as well as all Function graphs should be normalized or not.
- **max_iterations** (*int*) – The maximum number of iterations that each basic block should be "executed". 1 by default. Larger numbers of iterations are usually required for complex analyses like loop analysis.
- **address_whitelist** (*iterable*) – A list of allowed addresses. Any basic blocks outside of this collection of addresses will be ignored.
- **base_graph** (*networkx.DiGraph*) – A basic control flow graph to follow. Each node inside this graph must have the following properties: *addr* and *size*. CFG recovery will strictly follow nodes and edges shown in the graph, and discard any control flow that does not follow an existing edge in the base graph. For example, you can pass in a Function local transition graph as the base graph, and CFGEmulated will traverse nodes and edges and extract useful information.
- **iropt_level** (*int*) – The optimization level of VEX IR (0, 1, 2). The default level will be used if *iropt_level* is None.
- **max_steps** (*int*) – The maximum number of basic blocks to recover forthe longest path from each start before pausing the recovery procedure.
- **state_add_options** – State options that will be added to the initial state.
- **state_remove_options** – State options that will be removed from the initial state.

**copy**()

Make a copy of the CFG.

**Return type**
*CFGEmulated*

**Returns**
A copy of the CFG instance.

**resume**(*starts=None*, *max_steps=None*)

Resume a paused or terminated control flow graph recovery.

**Parameters**

- **starts** (*iterable*) – A collection of new starts to resume from. If *starts* is None, we will resume CFG recovery from where it was paused before.
- **max_steps** (*int*) – The maximum number of blocks on the longest path starting from each start before pausing the recovery.

**Returns**
None

**remove_cycles**()

Forces graph to become acyclic, removes all loop back edges and edges between overlapped loop headers and their successors.

**downsize**()

Remove saved states from all CFGNodes to reduce memory usage.

**Returns**
None

**unroll_loops**(*max_loop_unrolling_times*)

Unroll loops for each function. The resulting CFG may still contain loops due to recursion, function calls, etc.

**Parameters**
**max_loop_unrolling_times** (*int*) – The maximum iterations of unrolling.

**Returns**
None

**force_unroll_loops**(*max_loop_unrolling_times*)

Unroll loops globally. The resulting CFG does not contain any loop, but this method is slow on large graphs.

**Parameters**
**max_loop_unrolling_times** (*int*) – The maximum iterations of unrolling.

**Returns**
None

**immediate_dominators**(*start*, *target_graph=None*)

Get all immediate dominators of sub graph from given node upwards.

**Parameters**

- **start** (*str*) – id of the node to navigate forwards from.
- **target_graph** (*networkx.classes.digraph.DiGraph*) – graph to analyse, default is self.graph.

**Returns**
each node of graph as index values, with element as respective node's immediate dominator.

**Return type**
dict

**immediate_postdominators**(*end*, *target_graph=None*)

Get all immediate postdominators of sub graph from given node upwards.

**Parameters**

- **start** (*str*) – id of the node to navigate forwards from.
- **target_graph** (*networkx.classes.digraph.DiGraph*) – graph to analyse, default is self.graph.

**Returns**
each node of graph as index values, with element as respective node's immediate dominator.

**Return type**
dict

**remove_fakerets**()

Get rid of fake returns (i.e., Ijk_FakeRet edges) from this CFG

**Returns**
None

**get_topological_order**(*cfg_node*)

Get the topological order of a CFG Node.

**Parameters**
**cfg_node** – A CFGNode instance.

**Returns**
An integer representing its order, or None if the CFGNode does not exist in the graph.

**get_subgraph**(*starting_node*, *block_addresses*)

Get a sub-graph out of a bunch of basic block addresses.

**Parameters**

- **starting_node** (CFGNode) – The beginning of the subgraph
- **block_addresses** (*iterable*) – A collection of block addresses that should be included in the subgraph if there is a path between *starting_node* and a CFGNode with the specified address, and all nodes on the path should also be included in the subgraph.

**Returns**
A new CFG that only contain the specific subgraph.

**Return type**
*CFGEmulated*

**get_function_subgraph**(*start*, *max_call_depth=None*)

Get a sub-graph of a certain function.

**Parameters**

- **start** – The function start. Currently it should be an integer.
- **max_call_depth** – Call depth limit. None indicates no limit.

**Returns**
A CFG instance which is a sub-graph of self.graph

**property context_sensitivity_level**

**property graph:** *SpillingCFG*

**property unresolvables**

Get those SimRuns that have non-resolvable exits.

**Returns**
A set of SimRuns

**Return type**
set

**property deadends**

Get all CFGNodes that has an out-degree of 0

**Returns**
A list of CFGNode instances

**Return type**
list

class angr.analyses.**CFGFast**

Bases: *ForwardAnalysis*[*CFGNode*, *CFGNode*, *CFGJob*, int, object], *CFGBase*

We find functions inside the given binary, and build a control-flow graph in very fast manners: instead of simulating program executions, keeping track of states, and performing expensive data-flow analysis, CFGFast will only perform light-weight analyses combined with some heuristics, and with some strong assumptions.

In order to identify as many functions as possible, and as accurate as possible, the following operation sequence is followed:

# Active scanning

- If the binary has "function symbols" (TODO: this term is not accurate enough), they are starting points of the code scanning
- If the binary does not have any "function symbol", we will first perform a function prologue scanning on the entire binary, and start from those places that look like function beginnings
- Otherwise, the binary's entry point will be the starting point for scanning

# Passive scanning

- After all active scans are done, we will go through the whole image and scan all code pieces

Due to the nature of those techniques that are used here, a base address is often not required to use this analysis routine. However, with a correct base address, CFG recovery will almost always yield a much better result. A custom analysis, called GirlScout, is specifically made to recover the base address of a binary blob. After the base address is determined, you may want to reload the binary with the new base address by creating a new Project object, and then re-recover the CFG.

**PROLOGUE_SCAN_PADDING = 64**

**PRINTABLES = b'0123456789abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ!"#$%&**
**'()*+,-./:;<=>?@[\\]^_`{|}~ \t\n\r'**

**SPECIAL_THUNKS = {'AMD64':**
**{b'\xe8\x07\x00\x00\x00\xf3\x90\x0f\xae\xe8\xeb\xf9H\x89\x04$\xc3': ('jmp', 'rax'),**
**b'\xe8\x07\x00\x00\x00\xf3\x90\x0f\xae\xe8\xeb\xf9H\x8dd$\x08\xc3': ('ret',)}}**

**tag: str = 'CFGFast'**

**addr_type: Literal['int', 'block_id', 'soot'] = 'int'**

**__init__**(*binary=None*, *objects=None*, *regions=None*, *pickle_intermediate_results=False*, *symbols=True*, *function_prologues=None*, *resolve_indirect_jumps=True*, *force_segment=False*, *force_smart_scan=None*, *force_complete_scan=False*, *indirect_jump_target_limit=100000*, *data_references=True*, *cross_references=False*, *normalize=False*, *start_at_entry=True*, *function_starts=None*, *extra_memory_regions=None*, *data_type_guessing_handlers=None*, *arch_options=None*, *indirect_jump_resolvers=None*, *base_state=None*, *exclude_sparse_regions=True*, *skip_specific_regions=True*, *heuristic_plt_resolving=None*, *detect_tail_calls=False*, *low_priority=False*, *cfb=None*, *model=None*, *resume_state=None*, *eh_frame=True*, *eh_frame_boundaries=True*, *exceptions=True*, *skip_unmapped_addrs=True*, *nodecode_window_size=2048*, *nodecode_threshold=0.6*, *nodecode_step=16483*, *repeating_byte_run_threshold=64*, *check_funcret_max_job=500*, *indirect_calls_always_return=None*, *jumptable_resolver_resolves_calls=None*, *retedges=False*, *drop_bad_funcs=True*, *treat_functions_as_complete=True*, *start=None*, *end=None*, *collect_data_references=None*, *extra_cross_references=None*, *elf_eh_frame=None*, ***extra_arch_options*)

**Parameters**

- **binary** – The binary to recover CFG on. By default the main binary is used.
- **objects** – A list of objects to recover the CFG on. By default it will recover the CFG of all loaded objects.
- **regions** (*iterable*) – A list of tuples in the form of (start address, end address) describing memory regions that the CFG should cover.
- **pickle_intermediate_results** (*bool*) – If we want to store the intermediate results or not.
- **symbols** (*bool*) – Get function beginnings from symbols in the binary.
- **function_prologues** (bool | None) – Scan the binary for function prologues, and use those positions as function beginnings
- **resolve_indirect_jumps** (*bool*) – Try to resolve indirect jumps. This is necessary to resolve jump targets from jump tables, etc.
- **force_segment** (*bool*) – Force CFGFast to rely on binary segments instead of sections.
- **force_complete_scan** (*bool*) – Perform a complete scan on the binary and maximize the number of identified code blocks.
- **data_references** (*bool*) – Enables the collection of references to data used by individual instructions. This does not collect 'cross-references', particularly those that involve multiple instructions. For that, see *cross_references*
- **cross_references** (*bool*) – Whether CFGFast should collect "cross-references" from the entire program or not. This will populate the knowledge base with references to and from each recognizable address constant found in the code. Note that, because this performs constant propagation on the entire program, it may be much slower and consume more memory. This option implies *data_references=True*.
- **normalize** (*bool*) – Normalize the CFG as well as all function graphs after CFG recovery.
- **start_at_entry** (*bool*) – Begin CFG recovery at the entry point of this project. Setting it to False prevents CFGFast from viewing the entry point as one of the starting points of code scanning.
- **function_starts** (*list*) – A list of extra function starting points. CFGFast will try to resume scanning from each address in the list.
- **extra_memory_regions** (*list*) – A list of 2-tuple (start-address, end-address) that shows extra memory regions. Integers falling inside will be considered as pointers.
- **indirect_jump_resolvers** (*list*) – A custom list of indirect jump resolvers. If this list is None or empty, default indirect jump resolvers specific to this architecture and binary types will be loaded.
- **base_state** – A state to use as a backer for all memory loads
- **detect_tail_calls** (*bool*) – Enable aggressive tail-call optimization detection.
- **eh_frame** (*bool*) – Retrieve function starts (and maybe sizes later) from the .eh_frame of ELF binaries or exception records of PE binaries.
- **eh_frame_boundaries** (*bool*) – Treat function starts recorded in the .eh_frame of ELF binaries as hard function boundaries while tracing, the same way symbol addresses are treated. Without it, a tail-called function that is reached through a jump before it is reached through a call is absorbed into the caller. Only used if eh_frame is enabled.

- **skip_unmapped_addrs** – Ignore all branches into unmapped regions. True by default. You may want to set it to False if you are analyzing manually patched binaries or malware samples.
- **indirect_calls_always_return** (bool | None) – Should CFG assume indirect calls must return or not. Assuming indirect calls must return will significantly reduce the number of constant propagation runs, but may reduce the overall CFG recovery precision when facing non-returning indirect calls. By default, we only assume indirect calls always return for large binaries (region > 50KB).
- **jumptable_resolver_resolves_calls** (bool | None) – Whether JumpTableResolver should resolve indirect calls or not. Most indirect calls in C++ binaries or UEFI binaries cannot be resolved using jump table resolver and must be resolved using their specific resolvers. By default, we will only disable JumpTableResolver from resolving indirect calls for large binaries (region > 50 KB).
- **repeating_byte_run_threshold** – The minimum length of a run of one repeated byte that CFGFast refuses to decode as code. Such runs are filler, but many of them decode cleanly (e.g., 0x91 is *xchg ecx, eax* on x86), so linear disassembly would otherwise walk through them forever. Runs of the architecture's nop byte are exempt because execution really does flow through them. Set it to 0 to disable the check.
- **check_funcret_max_job** – When popping return-site jobs out of the job queue, angr will prioritize jobs for which the callee is known to return. This check may be slow when there are a large amount of jobs in different caller functions, and this situation often occurs in obfuscated binaries where many functions never return. This parameter acts as a threshold to disable this check when the number of jobs in the queue exceeds this threshold.
- **start** (*int*) – (Deprecated) The beginning address of CFG recovery.
- **end** (*int*) – (Deprecated) The end address of CFG recovery.
- **arch_options** (CFGArchOptions) – Architecture-specific options.
- **extra_arch_options** – Any key-value pair in kwargs will be seen as an arch-specific option and will be used to set the option value in self._arch_options.
- **retedges** (bool) – Whether to add return edges (from function endpoints to their return sites) in the CFG. Return edges are not added by default because they are often not useful during analysis; You can set retedges to True or call make_return_edges() after CFG recovery to create return edges. Note that this option does not impact function graphs.
- **model** – An existing CFGModel to write into. When a partial model from a previously aborted CFG recovery is passed in, recovery resumes on top of it: bytes covered by existing nodes and memory data are treated as already scanned and will not be re-lifted.
- **treat_functions_as_complete** (bool) – Whether post-analysis may treat the recovered functions as complete (drop bad functions, conclude returning=False for functions without return paths). Set to False for incremental runs that extend a partial model without completing it (see the resume recipes below).
- **resume_state** (*CFGResumeState* | None) – The resume_state captured by a previously aborted CFGFast instance. Its unprocessed jobs and unresolved indirect jumps are recreated (with their original function context) so that the recovery continues where it left off. Pass it together with model=.
- **progress_callback** – (Inherited from angr.Analysis.) Callback for CFG recovery progress. The callback receives (percentage, text=..., cfg=...) where cfg is this CFGFast instance; calling cfg.abort() from the callback gracefully aborts the analysis: the core

recovery loop stops at the next job boundary, post-analysis still runs and finalizes the partially recovered model, and cfg.should_abort remains True so callers can tell the model is partial.

- **show_progressbar** (*bool*) – (Inherited from angr.Analysis.) Show a progressbar during CFG recovery.
- **force_smart_scan** (*bool | None*)
- **drop_bad_funcs** (*bool*)

Aborting and resuming CFG recovery:

After a graceful abort (see progress_callback above), self.resume_state captures the jobs that were still unprocessed (with their function context) and the unresolved indirect jumps; self.unprocessed_job_addrs holds the corresponding addresses for informational purposes. To resume recovery, create a new CFGFast instance reusing the partial model. To resume global scanning and finish the entire binary, re-inject the captured state while keeping the seeding options (symbols, function_prologues, eh_frame, force_smart_scan) at their original values:

```
proj.analyses.CFGFast(model=partial_cfg.model, start_at_entry=False,
                      resume_state=partial_cfg.resume_state)
```

Do not pass unprocessed_job_addrs as function_starts instead: function_starts seeds are treated as function heads, which would promote unprocessed call return sites and intra-function jump targets to functions.

To only resume from specific addresses (they must not be part of the partial model already; seeding an already-scanned address is a no-op):

```
proj.analyses.CFGFast(model=partial_cfg.model, function_starts=[addr], start_at_
↪entry=False,
                      symbols=False, function_prologues=False, eh_frame=False,
                      force_smart_scan=False, force_complete_scan=False,
                      treat_functions_as_complete=False)
```

treat_functions_as_complete=False tells post-analysis that the resulting model is still partial: functions must not be dropped as bad, and returning=False must not be concluded for (possibly truncated) functions - such conclusions would poison a later full resume the same way an abort would without them being reset.

**Returns**
None

**Parameters**

- **function_prologues** (*bool | None*)
- **force_smart_scan** (*bool | None*)
- **resume_state** (*CFGResumeState | None*)
- **indirect_calls_always_return** (*bool | None*)
- **jumptable_resolver_resolves_calls** (*bool | None*)
- **retedges** (*bool*)
- **drop_bad_funcs** (*bool*)
- **treat_functions_as_complete** (*bool*)

**property graph:** *SpillingCFG*

property memory_data

property jump_tables

property insn_addr_to_memory_data

do_full_xrefs(*overlay_state=None*)

Perform xref recovery on all functions.

**Parameters**
**overlay** (SimState) – An overlay state for loading constant data.

**Returns**
None

drop_bad_functions()

make_return_edges()

For each returning function, create return edges in self.graph.

**Returns**
None

copy()

output()

class angr.analyses.CFGFastSoot

Bases: *CFGFast*

addr_type: Literal['int', 'block_id', 'soot'] = 'soot'

drop_bad_functions()

make_functions()

Revisit the entire control flow graph, create Function instances accordingly, and correctly put blocks into each function.

Although Function objects are crated during the CFG recovery, they are neither sound nor accurate. With a pre-constructed CFG, this method rebuilds all functions bearing the following rules:

- A block may only belong to one function.
- Small functions lying inside the startpoint and the endpoint of another function will be merged with the other function
- Tail call optimizations are detected.
- PLT stubs are aligned by 16.

**Returns**
None

class angr.analyses.CalleeCleanupFinder

Bases: *Analysis*

__init__(*starts=None*, *hook_all=False*)

analyze(*addr*)

class angr.analyses.**CallingConventionAnalysis**

Bases: *Analysis*

Analyze the calling convention of a function and guess a probable prototype.

The calling convention of a function can be inferred at both its call sites and the function itself. At call sites, we consider all register and stack variables that are not alive after the function call as parameters to this function. In the function itself, we consider all register and stack variables that are read but without initialization as parameters. Then we synthesize the information from both locations and make a reasonable inference of calling convention of this function.

**Variables**

- **_function** – The function to recover calling convention for.
- **_variable_manager** – A handy accessor to the variable manager.
- **_cfg** – A reference of the CFGModel of the current binary. It is used to discover call sites of the current function in order to perform analysis at call sites.
- **analyze_callsites** – True if we should analyze all call sites of the current function to determine the calling convention and arguments. This can be time-consuming if there are many call sites to analyze.
- **cc** (*SimCC* | None) – The recovered calling convention for the function.
- **_collect_facts** – True if we should run FunctionFactCollector to collect input arguments and return value size. False if input arguments and return value size are provided by the user.

__init__(*func*, *cfg=None*, *analyze_callsites=False*, *caller_func_addr=None*, *callsite_block_addr=None*, *callsite_insn_addr=None*, *func_graph=None*, *input_args=None*, *retval_size=None*, *extra_pop=None*, *collect_facts=False*, *collect_facts_arg_uses=False*, *collect_facts_arg_passthru=False*, *flavor=None*)

**Parameters**

- **flavor** (str | None) – The decompilation flavor whose callee prototypes are consulted (None: the default flavor).
- **func** (*Function | int | str | None*)
- **cfg** (*CFGModel | None*)
- **analyze_callsites** (*bool*)
- **caller_func_addr** (*int | None*)
- **callsite_block_addr** (*int | None*)
- **callsite_insn_addr** (*int | None*)
- **func_graph** (*networkx.DiGraph | None*)
- **input_args** (*list[SimRegArg | SimStackArg] | None*)
- **retval_size** (*int | None*)
- **extra_pop** (*int | None*)
- **collect_facts** (*bool*)
- **collect_facts_arg_uses** (*bool*)
- **collect_facts_arg_passthru** (*bool*)

**has_va_xmm_save_area_amd64**(*func*)

Detect the va_start prologue idiom that spills xmm0-xmm7 into the register save area (`test al, al; je ...; movaps [base+disp+16*i], xmm_i` for i in 0..7).

**Return type**
bool

**Parameters**
**func** (Function)

**is_va_start_amd64**(*func*)

**Return type**
tuple[bool, int | None]

**Parameters**
**func** (Function)

**class** angr.analyses.**ClassIdentifier**

Bases: *Analysis*

This is a class identifier for non stripped or partially stripped binaries, it identifies classes based on the demangled function names, and also assigns functions to their respective classes based on their names. It also uses the results from the VtableFinder analysis to assign the corresponding vtable to the classes.

self.classes contains a mapping between class names and SimCppClass objects

e.g. A::tool() and A::qux() belong to the class A

**__init__**()

**class** angr.analyses.**CodeCaveAnalysis**

Bases: *Analysis*

Best-effort static location of potential vacant code caves for possible code injection: - Padding functions - Unreachable code

**__init__**()

**codecaves**: list[*CodeCave*]

**class** angr.analyses.**CodeTagging**

Bases: *Analysis*

**__init__**(*func*)

**analyze**()

**has_xor**()

Detects if there is any xor operation in the function.

**Returns**
Tags

**has_bitshifts**()

Detects if there is any bitwise operation in the function.

**Returns**
Tags.

**has_sql**()

Detects if there is any reference to strings that look like SQL queries.

**class** angr.analyses.**CompleteCallingConventionsAnalysis**

Bases: *Analysis*

Implements full-binary calling convention analysis. During the initial analysis of a binary, you may set *recover_variables* to True so that it will perform variable recovery on each function before performing calling convention analysis.

**__init__**(*mode=CallingConventionAnalysisMode.FASTISH*, *recover_variables=False*, *low_priority=False*, *force=False*, *cfg=None*, *analyze_callsites=False*, *skip_signature_matched_functions=False*, *max_function_blocks=None*, *max_function_size=None*, *workers=0*, *cc_callback=None*, *prioritize_func_addrs=None*, *skip_other_funcs=False*, *auto_start=True*, *func_graphs=None*, *target_functions=None*, *flavor=None*)

**Parameters**

- **recover_variables** – Recover variables on each function before performing calling convention analysis.
- **low_priority** – Run in the background - periodically release GIL.
- **force** – Perform calling convention analysis on functions even if they have calling conventions or prototypes already specified (or previously recovered).
- **cfg** (*CFGFast* | *CFGModel* | None) – The control flow graph model, which will be passed to CallingConventionAnalysis.
- **analyze_callsites** (bool) – Consider artifacts at call sites when performing calling convention analysis.
- **skip_signature_matched_functions** (bool) – Do not perform calling convention analysis on functions that match against existing FLIRT signatures.
- **max_function_blocks** (int | None) – Do not perform calling convention analysis on functions with more than the specified number of blocks. Setting it to None disables this check.
- **max_function_size** (int | None) – Do not perform calling convention analysis on functions whose sizes are more than *max_function_size*. Setting it to None disables this check.
- **workers** (int) – Number of multiprocessing workers.
- **flavor** (str | None) – The decompilation flavor whose prototypes the analysis reads and writes (None: the default flavor).
- **mode** (CallingConventionAnalysisMode)
- **cc_callback** (*Callable | None*)
- **prioritize_func_addrs** (*list[int] | set[int] | None*)
- **skip_other_funcs** (*bool*)
- **auto_start** (*bool*)
- **func_graphs** (*dict[int, DiGraph] | None*)
- **target_functions** (*set[int] | None*)

**work**()

**prioritize_functions**(*func_addrs_to_prioritize*)

Prioritize the analysis of specified functions.

**Parameters**
**func_addrs_to_prioritize** (Iterable[int]) – A collection of function addresses to analyze first.

**static function_needs_variable_recovery**(*func*)

Check if running variable recovery on the function is the only way to determine the calling convention of the this function.

We do not need to run variable recovery to determine the calling convention of a function if: - The function is a SimProcedure. - The function is a PLT stub. - The function is a library function and we already know its prototype.

**Parameters**
**func** – The function object.

**Returns**
True if we must run VariableRecovery before we can determine what the calling convention of this function is. False otherwise.

**Return type**
bool

**class** angr.analyses.**CongruencyCheck**

Bases: *Analysis*

This is an analysis to ensure that angr executes things identically with different execution backends (i.e., unicorn vs vex).

**__init__**(*throw=False*)

Initializes a CongruencyCheck analysis.

**Parameters**
**throw** – whether to raise an exception if an incongruency is found.

**set_state_options**(*left_add_options=None*, *left_remove_options=None*, *right_add_options=None*, *right_remove_options=None*)

Checks that the specified state options result in the same states over the next *depth* states.

**set_states**(*left_state*, *right_state*)

Checks that the specified paths stay the same over the next *depth* states.

**set_simgr**(*simgr*)

**run**(*depth=None*)

Checks that the paths in the specified path group stay the same over the next *depth* bytes.

The path group should have a "left" and a "right" stash, each with a single path.

**compare_path_group**(*pg*)

**compare_states**(*sl*, *sr*)

Compares two states for similarity.

**compare_paths**(*pl*, *pr*)

**class** angr.analyses.**DataDependencyGraphAnalysis**

Bases: *Analysis*

This is a DYNAMIC data dependency graph that utilizes a given SimState to produce a DDG graph that is accurate to the path the program took during execution.

This analysis utilizes the SimActionData objects present in the provided SimState's action history to generate the dependency graph.

**__init__**(*end_state*, *start_from=None*, *end_at=None*, *block_addrs=None*)

**Parameters**

- **end_state** (*SimState*) – Simulation state used to extract all SimActionData
- **start_from** (int | None) – An address or None, Specifies where to start generation of DDG
- **end_at** (int | None) – An address or None, Specifies where to end generation of DDG
- **block_addrs** (list[int] | None) – List of block addresses that the DDG analysis should be run on

**property graph: DiGraph | None**

**property simplified_graph: DiGraph | None**

**property sub_graph: DiGraph | None**

**get_data_dep**(*g_node*, *include_tmp_nodes*, *backwards*)

**Return type**
DiGraph | None

**Parameters**

- **g_node** (BaseDepNode)
- **include_tmp_nodes** (*bool*)
- **backwards** (*bool*)

**class** angr.analyses.**Decompiler**

Bases: *Analysis*

The decompiler analysis.

Run this on a Function object for which a normalized CFG has been constructed. The fully processed output can be found in result.codegen.text

AIL graphs exposed on the result (both on a fresh run and on a cache hit, including caches reloaded from angrdb or the runtime-db spill):

- `ail_graph` (= `clinic.cc_graph`): the simplified graph before region identification.
- `clinic.graph`: the final graph after region identification and region simplification.
- `unoptimized_ail_graph` (= `clinic.unoptimized_graph`): a snapshot before the first structure-altering optimization pass; use it for an exact instruction-to-AIL mapping. Only built when `save_unoptimized_graph=True` is passed; otherwise this attribute is None on both fresh runs and cache hits.

Complexity guard: pathologically large functions (e.g. packer filler that linear disassembly turns into thousands of blocks) can keep the pipeline busy indefinitely, so two size limits are checked before the expensive work starts. `max_function_blocks` (default 50000, `DEFAULT_MAX_FUNCTION_BLOCKS`) bounds the number of CFG basic blocks and is checked before any AIL is built; `max_ail_statements` (default 1000000, `DEFAULT_MAX_AIL_STATEMENTS`) bounds the number of AIL statements and is checked right after the AIL graph is built. Both are ~10x the largest function in angr's test binary corpus. Either limit can be changed through the decompilation option of the same name, and setting one to 0 disables it. When a limit is exceeded, decompilation stops with an `AngrDecompilationComplexityError` naming the limit and the actual size: with `fail_fast=True` it is raised, otherwise it is recorded in `self.errors` (and in `kb.decompilations[...].errors`) and exposed as `complexity_error`, and `codegen` stays None.

The optimization passes come from `preset` (a name or a DecompilationPreset), or from an explicit `optimization_passes` list when no preset is given. `disable_opts` drops individual passes from the preset's list, which is how a caller asks for "this preset, minus that one pass" without restating it.

**__init__**(*func*, *cfg=None*, *options=None*, *preset=None*, *optimization_passes=None*, *disable_opts=None*, *sp_tracker_track_memory=True*, *peephole_optimizations=None*, *vars_must_struct=None*, *flavor=Flavors.DEFAULT_FLAVOR*, *expr_comments=None*, *stmt_comments=None*, *ite_exprs=None*, *binop_operators=None*, *decompile=True*, *regen_clinic=False*, *inline_functions=None*, *desired_variables=None*, *update_memory_data=True*, *want_full_graph=False*, *generate_code=True*, *use_cache=True*, *update_cache=True*, *expr_collapse_depth=16*, *clinic_graph=None*, *clinic_arg_vvars=None*, *clinic_start_stage=None*, *clinic_end_stage=None*, *clinic_skip_stages=()*, *static_vvars=None*, *static_buffers=None*, *codegen_cls=<class 'angr.analyses.decompiler.structured_codegen.c.CStructuredCodeGenerator'>*, *save_unoptimized_graph=False*, *go_sigs_rerun=True*)

**Parameters**

- **func** (Function | *str* | *int*)
- **cfg** (CFGFast | CFGModel | *None*)
- **preset** (*str* | DecompilationPreset | *None*)
- **peephole_optimizations** (*_PEEPHOLE_OPTIMIZATIONS_TYPE*)
- **vars_must_struct** (*set[str]* | *None*)
- **flavor** (*str*)
- **update_memory_data** (*bool*)
- **want_full_graph** (*bool*)
- **generate_code** (*bool*)
- **use_cache** (*bool*)
- **update_cache** (*bool*)
- **expr_collapse_depth** (*int*)
- **static_vvars** (*dict* | *None*)
- **static_buffers** (*dict* | *None*)
- **save_unoptimized_graph** (*bool*)
- **go_sigs_rerun** (*bool*)

**property complexity_error:** *AngrDecompilationComplexityError* | None

The complexity-limit violation that aborted this decompilation, or None if no limit was exceeded. Inspect `limit_name`, `limit`, and `actual` on it to decide whether to raise the limit or skip the function.

**reflow_variable_types**(*cache*)

Re-run type inference on an existing variable recovery result, then rerun codegen to generate new results.

**Returns**

**Parameters**
**cache** (DecompilationCache)

**find_data_references_and_update_memory_data**(*seq_node*)

**Parameters**
**seq_node** (SequenceNode)

**transform_graph_from_ssa**(*ail_graph*)

Translate an SSA AIL graph out of SSA form. This is useful for producing a non-SSA AIL graph for displaying in angr management.

**Parameters**
**ail_graph** (DiGraph) – The AIL graph to transform out of SSA form.

**Return type**
DiGraph

**Returns**
The translated AIL graph.

**transform_seqnode_from_ssa**(*seq_node*)

**Return type**
*SequenceNode*

**Parameters**
**seq_node** (SequenceNode)

**llm_refine**()

Use the configured LLM to suggest improved variable names, function names, and variable types. Returns True if any changes were made.

**Return type**
bool

**llm_suggest_variable_names**(*llm_client=None*, *code_text=None*, *raise_exc=False*)

Ask the LLM to suggest better variable names for the decompiled code. Returns True if any variables were renamed.

**Parameters**

- **raise_exc** (bool) – If True, exceptions from the LLM call are propagated to the caller. If False (default), exceptions are caught and the method returns False.
- **code_text** (*str | None*)

**Return type**
bool

**llm_suggest_function_name**(*llm_client=None*, *code_text=None*, *raise_exc=False*)

Ask the LLM to suggest a better function name. Only suggests rename for auto-generated names (starting with `sub_` or `fcn.`). Returns True if the function was renamed.

**Parameters**

- **raise_exc** (bool) – If True, exceptions from the LLM call are propagated to the caller.
- **code_text** (*str | None*)

**Return type**
bool

**llm_suggest_variable_types**(*llm_client=None*, *code_text=None*, *raise_exc=False*)

Ask the LLM to suggest better C types for variables. Returns True if any variable types were changed.

**Parameters**

- **raise_exc** (bool) – If True, exceptions from the LLM call are propagated to the caller.
- **code_text** (*str | None*)

**Return type**
bool

**llm_summarize_function**(*llm_client=None*, *code_text=None*, *raise_exc=False*)

Ask the LLM to produce a natural-language summary of what the decompiled function does. The summary is stored in the DecompilationCache and returned.

Returns the summary string, or None if summarization failed.

**Parameters**

- **raise_exc** (bool) – If True, exceptions from the LLM call are propagated to the caller.
- **code_text** (*str | None*)

**Return type**
str | None

**static options_to_params**(*options*)

Convert decompilation options to a dict of params.

**Parameters**
**options** (list[tuple[*DecompilationOption*, Any]]) – The decompilation options.

**Return type**
dict[str, Any]

**Returns**
A dict of keyword arguments.

**class** angr.analyses.**Disassembly**

Bases: *Analysis*

Produce formatted machine code disassembly.

**__init__**(*function=None*, *ranges=None*, *thumb=False*, *include_ir=False*, *block_bytes=None*)

**Parameters**

- **function** (*Function | None*)
- **ranges** (*Sequence[tuple[int, int]] | None*)
- **thumb** (*bool*)
- **include_ir** (*bool*)
- **block_bytes** (bytes | *None*)

**func_lookup**(*block*)

**parse_block**(*block*)

Parse instructions for a given block node

**Return type**
None

**Parameters**
**block** (BlockNode)

**render**(*formatting=None*, *show_edges=True*, *show_addresses=True*, *show_bytes=False*, *ascii_only=None*, *color=True*, *min_edge_depth=0*)

Render the disassembly to a string, with optional edges and addresses.

Color will be added by default, if enabled. To disable color pass an empty formatting dict.

**Return type**
str

**Parameters**

- **show_edges** (*bool*)
- **show_addresses** (*bool*)
- **show_bytes** (*bool*)
- **ascii_only** (*bool | None*)
- **color** (*bool*)
- **min_edge_depth** (*int*)

**class** angr.analyses.**DominanceFrontier**

Bases: Generic[T_co]

Computes the dominance frontier of all nodes in a function graph, and provides an easy-to-use interface for querying the frontier information.

**Overloads**

- **func** (), **func_graph** (networkx.DiGraph[T_co]), **entry** (T_co), **exception_edges** (bool) = False
- **func** (), **func_graph** (networkx.DiGraph[CodeNode] | None) = None, **entry** (*CodeNode* | None) = None, **exception_edges** (bool) = False

**__init__**(*func*, *func_graph=None*, *entry=None*, *exception_edges=False*)

**Overloads**

- **func** (), **func_graph** (networkx.DiGraph[T_co]), **entry** (T_co), **exception_edges** (bool) = False
- **func** (), **func_graph** (networkx.DiGraph[CodeNode] | None) = None, **entry** (*CodeNode* | None) = None, **exception_edges** (bool) = False

**Parameters**

- **func** (Function)
- **func_graph** (*networkx.DiGraph[T_co] | None*)

class angr.analyses.**FactCollector**

Bases: *Analysis*

An extremely fast analysis that extracts necessary facts of a function for CallingConventionAnalysis to make decision on the calling convention and prototype of a function.

**__init__**(*func*, *max_depth=100*, *track_arg_uses=False*, *track_arg_passthru=False*, *flavor=None*)

**Parameters**

- **func** (Function)
- **max_depth** (*int*)
- **track_arg_uses** (*bool*)
- **track_arg_passthru** (*bool*)
- **flavor** (*str | None*)

**callsites:** dict[int, tuple[*Function*, list[*FactData*]]]

callsite -> (callee, values passed to each argument of the callee's prototype, in prototype order)

**pushed_arg_callsites:** dict[int, tuple[*Function*, list[*FactData*]]]

callsite -> (callee without a usable prototype, values pushed to the outgoing stack). positions are not prototype indices.

**retval_incidental:** bool

True when every endpoint's write to the return register looks like a leftover rather than a return value: the value written is consumed again in the same block (stored, tested, passed on) after the write. A void function whose last instruction happens to load into rax looks exactly like a getter from the outside; this is the one local hint that it is not, and CallingConventionAnalysis only lets call-site evidence demote a prototype to void when it is set.

**retval_arg:** *SimRegArg* | None

the input argument register whose entry value is in the return register at every return site (an sret-style hidden result pointer, strcpy's dest, ...), or None

**extra_pop:** int | None

Number of bytes the callee pops after the return address on the stack, or None if we cannot determine.

**MAX_CONTINUATION_DEPTH = 3**

**MAX_CALLER_SITES = 16**

class angr.analyses.**FastConstantPropagation**

Bases: *Analysis*

An extremely fast constant propagation analysis that finds function-wide constant values with potentially high false negative rates.

**__init__**(*func*, *blocks=None*, *vex_cross_insn_opt=False*, *load_callback=None*)

**Parameters**

- **func** (Function)
- **blocks** (*set[Block] | None*)
- **vex_cross_insn_opt** (*bool*)
- **load_callback** (*Callable | None*)

class angr.analyses.**FlirtAnalysis**

Bases: *Analysis*

FlirtAnalysis accomplishes two purposes:

- If a FLIRT signature file is specified, it will match the given signature file against the current binary and rename recognized functions accordingly.
- If no FLIRT signature file is specified, it will use strings to determine possible libraries embedded in the current binary, and then match all possible signatures for the architecture.

**__init__**(*sig=None*, *max_mismatched_bytes=0*, *dry_run=False*, *match_named_functions=False*)

**Parameters**

- **sig** (FlirtSignature | *str* | *None*)
- **max_mismatched_bytes** (*int*)
- **dry_run** (*bool*)
- **match_named_functions** (*bool*)

class angr.analyses.**ForwardAnalysis**

Bases: Generic[AnalysisState, NodeType, JobType, JobKey, SuccessorType]

This is my very first attempt to build a static forward analysis framework that can serve as the base of multiple static analyses in angr, including CFG analysis, VFG analysis, DDG, etc.

In short, ForwardAnalysis performs a forward data-flow analysis by traversing a graph, compute on abstract values, and store results in abstract states. The user can specify what graph to traverse, how a graph should be traversed, how abstract values and abstract states are defined, etc.

ForwardAnalysis has a few options to toggle, making it suitable to be the base class of several different styles of forward data-flow analysis implementations.

ForwardAnalysis supports a special mode when no graph is available for traversal (for example, when a CFG is being initialized and constructed, no other graph can be used). In that case, the graph traversal functionality is disabled, and the optimal graph traversal order is not guaranteed. The user can provide a job sorting method to sort the jobs in queue and optimize traversal order.

Feel free to discuss with me (Fish) if you have any suggestions or complaints.

**__init__**(*order_jobs=False*, *allow_merging=False*, *allow_widening=False*, *status_callback=None*, *graph_visitor=None*)

Constructor

**Parameters**

- **order_jobs** (*bool*) – If all jobs should be ordered or not.
- **allow_merging** (*bool*) – If job merging is allowed.
- **allow_widening** (*bool*) – If job widening is allowed.
- **graph_visitor** (Optional[*GraphVisitor*[NodeType]]) – A graph visitor to provide successors.
- **status_callback** (Callable[[ForwardAnalysis], *Any*] | *None*)

**Returns**

None

property should_abort

Should the analysis be terminated. :return: True/False

property graph: DiGraph

property jobs

abort()

Abort the analysis :return: None

has_job(*job*)

Checks whether there exists another job which has the same job key. :type job: JobType :param job: The job to check.

**Return type**
bool

**Returns**
True if there exists another job with the same key, False otherwise.

**Parameters**
**job** (*JobType*)

downsize()

class angr.analyses.Identifier

Bases: *Analysis*

__init__(*cfg=None*, *require_predecessors=True*, *only_find=None*)

run(*only_find=None*)

can_call_same_name(*addr*, *name*)

get_func_info(*func*)

static constrain_all_zero(*before_state*, *state*, *regs*)

identify_func(*function*)

check_tests(*cfg_func*, *match_func*)

map_callsites()

do_trace(*addr_trace*, *reverse_accesses*, *func_info*)

get_call_args(*func*, *callsite*)

static get_reg_name(*arch*, *reg_offset*)

**Parameters**

- **arch** – the architecture
- **reg_offset** – Tries to find the name of a register given the offset in the registers.

**Returns**
The register name

find_stack_vars_x86(*func*)

**static make_initial_state**(*project*, *stack_length*)

**Returns**
an initial state with a symbolic stack and good options for rop

**static make_symbolic_state**(*project*, *reg_list*, *stack_length=80*)

converts an input state into a state with symbolic registers :return: the symbolic state

**class** angr.analyses.**InitializationFinder**

Bases: *ForwardAnalysis*, *Analysis*

Finds possible initializations for global data sections and generate an overlay to be used in other analyses later on.

**class** angr.analyses.**LanguageDetector**

Bases: *Analysis*

Detect the original programming language and compiler used to build a binary.

Supports detection of C (gcc, clang, msvc), Rust, Go, and Swift through multiple heuristic layers: DWARF debug info, .comment sections, symbol patterns, section names, and linked library names.

Usage:

```
result = project.analyses.LanguageDetector()
print(result.language)     # "rust"
print(result.compiler)     # "rustc"
print(result.confidence)   # "high"
print(result.evidence)     # ["symbol: __rust_alloc", ...]
```

**__init__**()

**property language:** str

**property compiler:** str | None

**property compiler_version:** str | None

**property confidence:** *LanguageDetectionConfidenceLevel*

**property evidence:** list[str]

**class** angr.analyses.**LoopAnalysis**

Bases: *Analysis*

Analyze loop nodes in a structured C code representation and extract relevant information about the loop, including - Loop block addresses - Loop exits - Loop type - Loop condition - Max iterations - Fixed iterations

**__init__**(*cfunc*)

**Parameters**
**cfunc** (CFunction)

**class** angr.analyses.**LoopFinder**

Bases: *Analysis*

Extracts all the loops from all the functions in a binary.

**__init__**(*functions=None*, *normalize=True*)

class angr.analyses.**LoopUnroller**

Bases: *Analysis*

Unroll a loop in an AIL graph for a specified number of iterations.

**__init__**(*graph*, *loop_body*, *unroll_times*, *save_original*, *loop_body_incomplete=False*)

**Parameters**

- **graph** (*DiGraph*)
- **loop_body** (*set[tuple[int, int]]*)
- **unroll_times** (*int*)
- **save_original** (*bool*)
- **loop_body_incomplete** (*bool*)

class angr.analyses.**PackingDetector**

Bases: *Analysis*

This analysis detects if a binary is likely packed or not. We may extend it to identify which packer is in use in the future.

**PACKED_MIN_BYTES = 256**

**PACKED_ENTROPY_MIN_THRESHOLD = 0.88**

**__init__**(*cfg=None*, *region_size_threshold=32*)

**Parameters**

- **cfg** (*CFGModel | None*)
- **region_size_threshold** (*int*)

**analyze**()

class angr.analyses.**PatchFinderAnalysis**

Bases: *Analysis*

Looks for binary patches using some basic heuristics: - Looking for interleaved functions - Looking for unaligned functions

**__init__**()

**atypical_alignments: list[*AtypicallyAlignedFunction*]**

**possibly_patched_out: list[*PatchedOutFunctionality*]**

class angr.analyses.**Pathfinder**

Bases: *Analysis*

**__init__**(*start_state*, *goal_addr*, *cfg*, *cache_size=10000*)

**Parameters**

- **start_state** (*SimState*)
- **goal_addr** (*int*)
- **cfg** (*CFGModel*)

**cache_state**(*state*)

**Parameters**
**state** (SimState)

**marker_to_state**(*marker*)

**Return type**
*SimState* | None

**Parameters**
**marker** (SimStateMarker)

**analyze**()

**Return type**
bool

**find_best_hypothesis_path**()

**Return type**
tuple[int, ...]

**diagnose_unsat**(*state*)

**Parameters**
**state** (SimState)

**test_path**(*bbl_addr_trace*)

**Return type**
*TestPathReport*

**Parameters**
**bbl_addr_trace** (*tuple[int, ...]*)

**class** angr.analyses.**PropagatorAnalysis**

Bases: *ForwardAnalysis*, *Analysis*

PropagatorAnalysis implements copy propagation. It propagates values (either constant values or variables) and expressions inside a block or across a function.

PropagatorAnalysis only supports VEX. For AIL, please use SPropagator.

PropagatorAnalysis performs certain arithmetic operations between constants, including but are not limited to:

- addition
- subtraction
- multiplication
- division
- xor

It also performs the following memory operations:

- Loading values from a known address
- Writing values to a stack variable

**property prop_key:** tuple[str | None, str, int, bool, bool, bool]

Gets a key that represents the function and the "flavor" of the propagation result.

property replacements

class angr.analyses.ProximityGraphAnalysis

Bases: *Analysis*

Generate a proximity graph.

__init__(*func*, *cfg_model*, *xrefs*, *decompilation=None*, *expand_funcs=None*)

**Parameters**

- **func** (Function)
- **cfg_model** (CFGModel)
- **xrefs** (XRefManager)
- **decompilation** (Decompiler | *None*)
- **expand_funcs** (*set[int]* | *None*)

class angr.analyses.ReachingDefinitionsAnalysis

Bases: *ForwardAnalysis*[*ReachingDefinitionsState*, , object, object, object], *Analysis*

ReachingDefinitionsAnalysis is a text-book implementation of a static data-flow analysis that works on either a function or a block. It supports both VEX and AIL. By registering observers to observation points, users may use this analysis to generate use-def chains, def-use chains, and reaching definitions, and perform other traditional data-flow analyses such as liveness analysis.

- I've always wanted to find a better name for this analysis. Now I gave up and decided to live with this name for the foreseeable future (until a better name is proposed by someone else).
- Aliasing is definitely a problem, and I forgot how aliasing is resolved in this implementation. I'll leave this as a post-graduation TODO.
- Some more documentation and examples would be nice.

__init__(*subject*, *func_graph=None*, *max_iterations=30*, *track_tmps=False*, *track_consts=True*, *observation_points=None*, *init_state=None*, *init_context=None*, *state_initializer=None*, *cc=None*, *function_handler=None*, *observe_all=False*, *visited_blocks=None*, *dep_graph=True*, *observe_callback=None*, *canonical_size=8*, *stack_pointer_tracker=None*, *use_callee_saved_regs_at_return=True*, *interfunction_level=0*, *track_liveness=True*, *func_addr=None*, *element_limit=5*, *merge_into_tops=True*, *variable_map=None*, *flavor=None*)

**Parameters**

- **subject** (*Subject* | Block | *Block* | *Function* | str) – The subject of the analysis: a function, or a single basic block
- **func_graph** – Alternative graph for function.graph.
- **max_iterations** – The maximum number of iterations before the analysis is terminated.
- **track_tmps** – Whether or not temporary variables should be taken into consideration during the analysis.
- **observation_points** (Iterable[tuple[Literal['insn', 'node', 'stmt', 'exit'], int | tuple[int, int] | tuple[int, int, int], *ObservationPointType*]] | None) – A collection of tuples of ("node"|"insn", ins_addr, OP_TYPE) defining where reaching definitions should be copied and stored. OP_TYPE can be OP_BEFORE or OP_AFTER.

- **init_state** (*ReachingDefinitionsState* | None) – An optional initialization state. The analysis creates and works on a copy. Default to None: the analysis then initialize its own abstract state, based on the given <Subject>.
- **init_context** – If init_state is not given, this is used to initialize the context field of the initial state's CodeLocation. The only default-supported type which may go here is a tuple of integers, i.e. a callstack. Anything else requires a custom FunctionHandler.
- **cc** – Calling convention of the function.
- **function_handler** (*FunctionHandler* | None) – The function handler to update the analysis state and results on function calls.
- **observe_all** – Observe every statement, both before and after.
- **visited_blocks** – A set of previously visited blocks.
- **dep_graph** (*DepGraph* | bool | None) – An initial dependency graph to add the result of the analysis to. Set it to None to skip dependency graph generation.
- **canonical_size** – The sizes (in bytes) that objects with an UNKNOWN_SIZE are treated as for operations where sizes are necessary.
- **dep_graph** – Set this to True to generate a dependency graph for the subject. It will be available as *result.dep_graph*.
- **interfunction_level** (int) – The number of functions we should recurse into. This parameter is only used if function_handler is not provided.
- **track_liveness** (bool) – Whether to track liveness information. This can consume sizeable amounts of RAM on large functions. (e.g. ~15GB for a function with 4k nodes)
- **merge_into_tops** (bool) – Merge known values into TOP if TOP is present. If True: {TOP} V {0xabc} = {TOP} If False: {TOP} V {0xabc} = {TOP, 0xabc}
- **flavor** (str | None) – The decompilation flavor whose prototypes of the function and its callees are used (None: the default flavor).
- **state_initializer** (RDAStateInitializer | *None*)
- **func_addr** (*int* | *None*)
- **element_limit** (*int*)

**property observed_results:** dict[tuple[str, int, int], *LiveDefinitions*]

**property all_definitions**

**property all_uses**

**property one_result**

**property dep_graph:** *DepGraph*

**property visited_blocks**

**get_reaching_definitions_by_insn**(*ins_addr*, *op_type*)

**get_reaching_definitions_by_node**(*node_addr*, *op_type*)

**node_observe**(*node_addr*, *state*, *op_type*, *node_idx=None*)

**Parameters**

- **node_addr** (int) – Address of the node.

- **state** (*ReachingDefinitionsState*) – The analysis state.
- **op_type** (*ObservationPointType*) – Type of the observation point. Must be one of the following: OP_BEFORE, OP_AFTER.
- **node_idx** (int | None) – ID of the node. Used in AIL to differentiate blocks with the same address.

**Return type**
None

**insn_observe**(*insn_addr*, *stmt*, *block*, *state*, *op_type*)

**Parameters**

- **insn_addr** (int) – Address of the instruction.
- **stmt** (*Statement* | IRStmt) – The statement.
- **block** (*Block* | Block) – The current block.
- **state** (*ReachingDefinitionsState*) – The abstract analysis state.
- **op_type** (*ObservationPointType*) – Type of the observation point. Must be one of the following: OP_BEORE, OP_AFTER.

**Return type**
None

**stmt_observe**(*stmt_idx*, *stmt*, *block*, *state*, *op_type*)

**Parameters**

- **stmt_idx** (int)
- **stmt** (*Statement* | IRStmt)
- **block** (*Block* | Block)
- **state** (*ReachingDefinitionsState*)
- **op_type** (*ObservationPointType*)

**Return type**
None

**Returns**

**exit_observe**(*node_addr*, *exit_stmt_idx*, *block*, *state*, *node_idx=None*)

**Parameters**

- **node_addr** (*int*)
- **exit_stmt_idx** (*int*)
- **block** (Block | *Block*)
- **state** (ReachingDefinitionsState)
- **node_idx** (*int* | *None*)

**property subject**

**callsites_to**(*target*)

**Return type**
Iterable[*FunctionCallRelationships*]

**Parameters**
**target** (*int* | *str* | Function)

**class** angr.analyses.**Reassembler**

Bases: *Analysis*

High-level representation of a binary with a linear representation of all instructions and data regions. After calling "symbolize", it essentially acts as a binary reassembler.

Tested on CGC, x86 and x86-64 binaries.

Disclaimer: The reassembler is an empirical solution. Don't be surprised if it does not work on some binaries.

**__init__**(*syntax='intel'*, *remove_cgc_attachments=True*, *log_relocations=True*)

**property instructions**

Get a list of all instructions in the binary

**Returns**
A list of (address, instruction)

**Return type**
tuple

**property relocations**

**property inserted_asm_before_label**

**property inserted_asm_after_label**

**property main_executable_regions**

return:

**property main_nonexecutable_regions**

return:

**disassemble_block**(*block*)

Disassemble a block using the assembly syntax configured for this Reassembler.

When AT&T syntax is requested, a capstone instance dedicated to this analysis is used, so that neither the project-wide Arch object nor the capstone instance cached on it is modified.

**Parameters**
**block** – The angr Block to disassemble.

**Returns**
A CapstoneBlock instance.

**Return type**
*CapstoneBlock*

**section_alignment**(*section_name*)

Get the alignment for the specific section. If the section is not found, 16 is used as default.

**Parameters**
**section_name** (*str*) – The section.

**Returns**
The alignment in bytes.

**Return type**
int

`main_executable_regions_contain`(*addr*)

**Parameters**
**addr**

**Returns**

`main_executable_region_limbos_contain`(*addr*)

Sometimes there exists a pointer that points to a few bytes before the beginning of a section, or a few bytes after the beginning of the section. We take care of that here.

**Parameters**
**addr** (*int*) – The address to check.

**Returns**
A 2-tuple of (bool, the closest base address)

**Return type**
tuple

`main_nonexecutable_regions_contain`(*addr*)

**Parameters**
**addr** (*int*) – The address to check.

**Returns**
True if the address is inside a non-executable region, False otherwise.

**Return type**
bool

`main_nonexecutable_region_limbos_contain`(*addr*, *tolerance_before=64*, *tolerance_after=64*)

Sometimes there exists a pointer that points to a few bytes before the beginning of a section, or a few bytes after the beginning of the section. We take care of that here.

**Parameters**
**addr** (*int*) – The address to check.

**Returns**
A 2-tuple of (bool, the closest base address)

**Return type**
tuple

`register_instruction_reference`(*insn_addr*, *ref_addr*, *sort*, *operand_offset*)

`register_data_reference`(*data_addr*, *ref_addr*)

`add_label`(*name*, *addr*)

Add a new label to the symbol manager.

**Parameters**

- **name** (*str*) – Name of the label.
- **addr** (*int*) – Address of the label.

**Returns**
None

**insert_asm**(*addr*, *asm_code*, *before_label=False*)

Insert some assembly code at the specific address. There must be an instruction starting at that address.

**Parameters**

- **addr** (*int*) – Address of insertion
- **asm_code** (*str*) – The assembly code to insert

**Returns**
None

**append_procedure**(*name*, *asm_code*)

Add a new procedure with specific name and assembly code.

**Parameters**

- **name** (*str*) – The name of the new procedure.
- **asm_code** (*str*) – The assembly code of the procedure

**Returns**
None

**append_data**(*name*, *initial_content*, *size*, *readonly=False*, *sort='unknown'*)

Append a new data entry into the binary with specific name, content, and size.

**Parameters**

- **name** (*str*) – Name of the data entry. Will be used as the label.
- **initial_content** (bytes) – The initial content of the data entry.
- **size** (*int*) – Size of the data entry.
- **readonly** (*bool*) – If the data entry belongs to the readonly region.
- **sort** (*str*) – Type of the data.

**Returns**
None

**remove_instruction**(*ins_addr*)

**Parameters**
**ins_addr**

**Returns**

**randomize_procedures**()

**Returns**

**symbolize**()

**assembly**(*comments=False*, *symbolized=True*)

**remove_cgc_attachments**()

Remove CGC attachments.

**Returns**
True if CGC attachments are found and removed, False otherwise

**Return type**
bool

**remove_unnecessary_stuff**()

Remove unnecessary functions and data

**Returns**
None

**remove_unnecessary_stuff_glibc**()

**fast_memory_load**(*addr*, *size*, *data_type*, *endness='Iend_LE'*)

Load memory bytes from loader's memory backend.

**Parameters**

- **addr** (*int*) – The address to begin memory loading.
- **size** (*int*) – Size in bytes.
- **data_type** – Type of the data.
- **endness** (*str*) – Endianness of this memory load.

**Returns**
Data read out of the memory.

**Return type**
int or *bytes* or str or None

**class** angr.analyses.**SLivenessAnalysis**

Bases: *Analysis*

Calculates LiveIn and LiveOut sets for each block in a partial-SSA function.

**__init__**(*func*, *func_graph*, *entry=None*, *func_addr=None*, *arg_vvars=None*)

**Parameters**

- **func** (Function)
- **func_graph** (*networkx.DiGraph[Block]*)
- **entry** (*Block | None*)
- **func_addr** (*int | None*)
- **arg_vvars** (*list[VirtualVariable] | None*)

**interference_graph**(*vvar_ids=None*)

Generate an interference graph based on the liveness analysis result.

**Parameters**
**vvar_ids** (set[int] | None) – When given, only keep edges whose both endpoints are in this set. The full graph is quadratic in the number of live vvars, so restrict it to the vvars whose interference the caller will actually query.

**Return type**
networkx.Graph[int]

**Returns**
A networkx.Graph instance.

**live_vars_by_stmt**()

Get a mapping from statements to live variables at the point of the statement.

**Return type**
defaultdict[, dict[int, *VVarSet*]]

**Returns**
A dictionary mapping statements to sets of live variable IDs.

**class** angr.analyses.**SPropagator**

Bases: object

Constant and expression propagation that only supports SSA AIL graphs.

Deliberately not an Analysis for better speed.

**__init__**(*project*, *subject*, ***, *ail_manager*, *func_graph=None*, *only_consts=True*, *stack_pointer_tracker=None*, *func_args=None*, *func_addr=None*, *stack_arg_offsets=None*)

**Parameters**

- **project** (Project)
- **subject** (Block | Function)
- **ail_manager** (*Manager*)
- **func_graph** (*networkx.DiGraph | None*)
- **only_consts** (*bool*)
- **func_args** (*set[VirtualVariable] | None*)
- **func_addr** (*int | None*)
- **stack_arg_offsets** (*set[int] | None*)

**property replacements**

**property dead_vvar_ids**

**static is_global_variable_updated**(*func_graph*, *block_dict*, *varid*, *gv_addr*, *gv_size*, *defloc*, *useloc*)

**Return type**
bool

**Parameters**

- **varid** (*int*)
- **gv_addr** (*int*)
- **gv_size** (*int*)
- **defloc** (AILCodeLocation)
- **useloc** (AILCodeLocation)

**static is_vvar_used_for_addr_loading_switch_case**(*uselocs*, *blocks*)

Check if a virtual variable is used for loading an address in a switch-case construct.

**Parameters**

- **uselocs** (set[*AILCodeLocation*]) – The use locations of the virtual variable.
- **blocks** – All blocks of the current function.

**Return type**
bool

**Returns**
True if the virtual variable is used for loading an address in a switch-case construct, False otherwise.

**static replace**(*replacements*, *loc*, *expr*, *value*)

**Return type**
None

**Parameters**

- **replacements** (*dict[AILCodeLocation, dict[VirtualVariable | Tmp, Expression]]*)
- **loc** (AILCodeLocation)
- **expr** (VirtualVariable | Tmp)
- **value** (Expression)

**class** angr.analyses.**SPropagatorAnalysis**

Bases: *Analysis*, *SPropagator*

A wrapper around SPropagator to make it an Analysis.

**__init__**(**args*, ***kwargs*)

**class** angr.analyses.**SReachingDefinitions**

Bases: object

Constant and expression propagation that only supports SSA AIL graphs.

Deliberately not an Analysis: it is instantiated hundreds of times per decompilation (often once per block), so it skips the analysis-factory ceremony. Instantiate it directly with the project as the first argument; exceptions always propagate.

**__init__**(*project*, *subject*, *func_addr=None*, *func_graph=None*, *func_args=None*, *use_callee_saved_regs_at_return=False*, *track_tmps=False*, *variable_map=None*)

**Parameters**

- **project** (Project)
- **func_addr** (*int | None*)
- **func_graph** (*networkx.DiGraph[Block] | None*)
- **func_args** (*set[VirtualVariable] | None*)
- **use_callee_saved_regs_at_return** (*bool*)
- **track_tmps** (*bool*)

**class** angr.analyses.**SReachingDefinitionsAnalysis**

Bases: *Analysis*, *SReachingDefinitions*

A wrapper around SReachingDefinitions to make it usable as an Analysis and registered in the analysis hub.

**__init__**(*subject*, *func_addr=None*, *func_graph=None*, *func_args=None*, *use_callee_saved_regs_at_return=False*, *track_tmps=False*, *variable_map=None*)

**Parameters**

- **func_addr** (*int | None*)
- **func_graph** (*networkx.DiGraph[Block] | None*)
- **func_args** (*set[VirtualVariable] | None*)
- **use_callee_saved_regs_at_return** (*bool*)
- **track_tmps** (*bool*)

class angr.analyses.**SelfModifyingCodeAnalysis**

Bases: *Analysis*

Determine if some piece of code is self-modifying.

This determination is made by simply executing. If an address is executed that is also written to, the code is determined to be self-modifying. The determination is stored in the *result* property. The *regions* property contains a list of (addr, length) regions that were both written to and executed.

**__init__**(*subject*, *max_bytes=0*, *state=None*)

**Parameters**

- **subject** (int | str | *Function* | None) – Subject of analysis
- **max_bytes** (int) – Maximum number of bytes from subject address. 0 for no limit (default).
- **state** (*SimState* | None) – State to begin executing from.

**regions**: list[tuple[int, int]]

**result**: bool

class angr.analyses.**SootClassHierarchy**

Bases: *Analysis*

Generate complete hierarchy.

**__init__**()

**init_hierarchy**()

**has_super_class**(*cls*)

**is_subclass_including**(*cls_child*, *cls_parent*)

**is_subclass**(*cls_child*, *cls_parent*)

**is_visible_method**(*cls*, *method*)

**is_visible_class**(*cls_from*, *cls_to*)

**get_super_classes**(*cls*)

**get_super_classes_including**(*cls*)

**get_implementers**(*interface*)

**get_sub_interfaces_including**(*interface*)

**get_sub_interfaces**(*interface*)

**get_sub_classes**(*cls*)

**get_sub_classes_including**(*cls*)

**resolve_abstract_dispatch**(*cls*, *method*)

**resolve_concrete_dispatch**(*cls*, *method*)

**resolve_special_dispatch**(*method*, *container*)

**resolve_invoke**(*invoke_expr*, *method*, *container*)

**class** angr.analyses.**StackPointerTracker**

Bases: *Analysis*, *ForwardAnalysis*

Track the offset of stack pointer at the end of each basic block of a function.

**__init__**(*func*, *reg_offsets*, *block=None*, *track_memory=True*, *cross_insn_opt=True*, *initial_reg_values=None*, *resilient=True*, *cross_insn_opt_callback=None*, *flavor=None*)

**Parameters**

- **flavor** (str | None) – The decompilation flavor whose callee and call-site prototypes are consulted (None: the default flavor).
- **func** (*Function | None*)
- **reg_offsets** (*set[int]*)
- **block** (*Block | None*)
- **resilient** (*bool*)
- **cross_insn_opt_callback** (*Callable[[int, int], bool] | None*)

**offset_after**(*addr*, *reg*)

**offset_before**(*addr*, *reg*)

**offset_after_block**(*block_addr*, *reg*)

**offset_before_block**(*block_addr*, *reg*)

**constant_after**(*addr*, *reg*)

**constant_before**(*addr*, *reg*)

**constant_after_block**(*block_addr*, *reg*)

**constant_before_block**(*block_addr*, *reg*)

**property inconsistent**

**inconsistent_for**(*reg*)

**offsets_for**(*reg*)

**callee_cleanup_size_at**(*node*)

The number of bytes this analysis assumes the callee pops at the call site ending node.

**Return type**
int

class angr.analyses.StaticHooker

Bases: *Analysis*

This analysis works on statically linked binaries - it finds the library functions statically linked into the binary and hooks them with the appropriate simprocedures.

Right now it only works on unstripped binaries, but hey! There's room to grow!

__init__(*library*, *binary=None*)

class angr.analyses.StaticObjectFinder

Bases: *Analysis*

**This analysis tries to find objects on the heap based on calls to new(), and subsequent calls to constructors with**
the 'this' pointer

__init__()

class angr.analyses.Typehoon

Bases: *Analysis*

A spiritual tribute to the long-standing typehoon project that @jmg (John Grosen) worked on during his days in the angr team. Now I feel really bad of asking the poor guy to work directly on VEX IR without any fancy static analysis support as we have right now...

Typehoon analysis implements a pushdown system that simplifies and solves type constraints. Our type constraints are largely an implementation of the paper Polymorphic Type Inference for Machine Code by Noonan, Loginov, and Cok from GrammaTech (with missing functionality support and bugs, of course). Type constraints are collected by running VariableRecoveryFast (maybe VariableRecovery later as well) on a function, and then solved using this analysis.

User may specify ground truth, which will override all types at certain program points during constraint solving.

__init__(*constraints*, *func_var*, *ground_truth=None*, *var_mapping=None*, *must_struct=None*, *stackvar_max_sizes=None*, *stack_offset_tvs=None*, *constraint_set_degradation_threshold=150*, *type_translator=None*, *tv_manager=None*)

**Parameters**

- **constraints**
- **ground_truth** – A set of SimType-style solutions for some or all type variables. They will be respected during type solving.
- **var_mapping** (dict[*SimVariable*, set[*TypeVariable*]] | None)
- **must_struct** (set[*TypeVariable*] | None)
- **stackvar_max_sizes** (*dict[TypeVariable, int] | None*)
- **stack_offset_tvs** (*dict[int, TypeVariable] | None*)
- **constraint_set_degradation_threshold** (*int*)
- **type_translator** (*TypeTranslator | None*)
- **tv_manager** (*TypeVariableManager | None*)

update_variable_types(*func_addr*, *var_to_typevars*, *stack_offset_tvs=None*, *flavor=None*)

**Parameters**

- **flavor** (str | None) – The decompilation flavor whose global manager receives the types when func_addr is "global".

- **func_addr** (*int | str*)
- **var_to_typevars** (*dict[SimVariable, set[TypeVariable]]*)
- **stack_offset_tvs** (*dict[int, TypeVariable] | None*)

**Return type**
None

**pp_constraints**()

Pretty-print constraints between *variables* using the variable mapping.

**Return type**
None

**pp_solution**()

Pretty-print solutions using the variable mapping.

**Return type**
None

**class** angr.analyses.**VariableRecovery**

Bases: *ForwardAnalysis*, *VariableRecoveryBase*

Recover "variables" from a function using forced execution.

While variables play a very important role in programming, it does not really exist after compiling. However, we can still identify and recovery their counterparts in binaries. It is worth noting that not every variable in source code can be identified in binaries, and not every recognized variable in binaries have a corresponding variable in the original source code. In short, there is no guarantee that the variables we identified/recognized in a binary are the same variables in its source code.

This analysis uses heuristics to identify and recovers the following types of variables: - Register variables. - Stack variables. - Heap variables. (not implemented yet) - Global variables. (not implemented yet)

This analysis takes a function as input, and performs a data-flow analysis on nodes. It runs concrete execution on every statement and hooks all register/memory accesses to discover all places that are accessing variables. It is slow, but has a more accurate analysis result. For a fast but inaccurate variable recovery, you may consider using VariableRecoveryFast.

This analysis follows SSA, which means every write creates a new variable in registers or memory (statck, heap, etc.). Things may get tricky when overlapping variable (in memory, as you cannot really have overlapping accesses to registers) accesses exist, and in such cases, a new variable will be created, and this new variable will overlap with one or more existing variables. A decision procedure (which is pretty much TODO) is required at the end of this analysis to resolve the conflicts between overlapping variables.

**__init__**(*func*, *max_iterations=20*, *store_live_variables=False*)

**Parameters**
**func** (*knowledge.Function*) – The function to analyze.

**class** angr.analyses.**VariableRecoveryFast**

Bases: *ForwardAnalysis*, *VariableRecoveryBase*

Recover "variables" from a function by keeping track of stack pointer offsets and pattern matching VEX statements.

If calling conventions are recovered prior to running VariableRecoveryFast, variables can be recognized more accurately. However, it is not a requirement. In this case, the function graph you pass must contain information indicating the call-out sites inside the analyzed function. These graph edges must be annotated with either `"type": "call"` or `"outside": True`.

**Parameters**
**flavor** (str | None) – The decompilation flavor on whose behalf variables are recovered. Only "rust" lifts types through the Rust type translator; None (the default) recovers C types.

class angr.analyses.**Veritesting**

Bases: *Analysis*

An exploration technique made for condensing chunks of code to single (nested) if-then-else constraints via CFG accurate to conduct Static Symbolic Execution SSE (conversion to single constraint)

**cfg_cache = {}**

**all_stashes = ('successful', 'errored', 'deadended', 'deviated', 'unconstrained')**

**__init__**(*input_state*, *boundaries=None*, *loop_unrolling_limit=10*, *enable_function_inlining=False*, *terminator=None*, *deviation_filter=None*)

SSE stands for Static Symbolic Execution, and we also implemented an extended version of Veritesting (Avgerinos, Thanassis, et al, ICSE 2014).

**Parameters**

- **input_state** – The initial state to begin the execution with.
- **boundaries** – Addresses where execution should stop.
- **loop_unrolling_limit** – The maximum times that Veritesting should unroll a loop for.
- **enable_function_inlining** – Whether we should enable function inlining and syscall inlining.
- **terminator** – A callback function that takes a state as parameter. Veritesting will terminate if this function returns True.
- **deviation_filter** – A callback function that takes a state as parameter. Veritesting will put the state into "deviated" stash if this function returns True.

**is_not_in_cfg**(*s*)

Returns if s.addr is not a proper node in our CFG.

**Parameters**
**s** (SimState) – The SimState instance to test.

**Returns bool**
False if our CFG contains p.addr, True otherwise.

**is_overbound**(*state*)

Filter out all states that run out of boundaries or loop too many times.

param SimState state: SimState instance to check returns bool: True if outside of mem/loop_ctr boundary

class angr.analyses.**VtableFinder**

Bases: *Analysis*

This analysis locates Vtables in a binary based on heuristics taken from - "Reconstruction of Class Hierarchies for Decompilation of C++ Programs"

**__init__**()

**is_cross_referenced**(*addr*)

**is_function**(*addr*)

**analyze**()

**create_extract_vtable**(*start_addr*, *sec_size*)

**class** angr.analyses.**XRefsAnalysis**

Bases: *ForwardAnalysis*, *Analysis*

XRefsAnalysis recovers in-depth x-refs (cross-references) in disassembly code.

Here is an example:

```
.text:
000023C8                LDR     R2, =time_now
000023CA                LDR     R3, [R2]
000023CC                ADDS    R3, #1
000023CE                STR     R3, [R2]
000023D0                BX      LR

.bss:
1FFF36F4 time_now       % 4
```

You will have the following x-refs for time_now:

```
23c8 - offset
23ca - read access
23ce - write access
```

angr.analyses.**register_analysis**(*cls*, *name*)

### 10.3.1 angr.analyses.analysis

**class** angr.analyses.analysis.**AnalysisLogEntry**

Bases: object

**__init__**(*message*, *exc_info=False*)

**format**()

**Return type**
str

**class** angr.analyses.analysis.**AnalysesHub**

Bases: *PluginVendor*[Any]

This class contains functions for all the registered and runnable analyses,

**__init__**(*project*)

class angr.analyses.analysis.**KnownAnalysesPlugin**

Bases: Protocol

**Identifier:** type[*Identifier*]

**CalleeCleanupFinder:** type[*CalleeCleanupFinder*]

**VSA_DDG:** type[*VSA_DDG*]

**CDG:** type[*CDG*]

**BinDiff:** type[*BinDiff*]

**CFGEmulated:** type[*CFGEmulated*]

**CFB:** type[*CFBlanket*]

**CFBlanket:** type[*CFBlanket*]

**CFG:** type[*CFG*]

**CFGFast:** type[*CFGFast*]

**StaticHooker:** type[*StaticHooker*]

**DDG:** type[*DDG*]

**CongruencyCheck:** type[*CongruencyCheck*]

**Reassembler:** type[*Reassembler*]

**BackwardSlice:** type[*BackwardSlice*]

**BinaryOptimizer:** type[*BinaryOptimizer*]

**VFG:** type[*VFG*]

**LoopFinder:** type[*LoopFinder*]

**Disassembly:** type[*Disassembly*]

**Veritesting:** type[*Veritesting*]

**CodeTagging:** type[*CodeTagging*]

**BoyScout:** type[*BoyScout*]

**VariableRecoveryFast:** type[*VariableRecoveryFast*]

**VariableRecovery:** type[*VariableRecovery*]

**ReachingDefinitions:** type[*ReachingDefinitionsAnalysis*]

**CompleteCallingConventions:** type[*CompleteCallingConventionsAnalysis*]

**Clinic:** type[*Clinic*]

**Propagator:** type[*PropagatorAnalysis*]

**XRefs:** type[*XRefsAnalysis*]

**SLiveness:** type[*SLivenessAnalysis*]

**SReachingDefinitions:** type[*SReachingDefinitionsAnalysis*]

**__init__**(**args*, ***kwargs*)

class angr.analyses.analysis.**AnalysesHubWithDefault**

Bases: *AnalysesHub*, *KnownAnalysesPlugin*

This class has type-hinting for all built-in analyses plugin

class angr.analyses.analysis.**AnalysisFactory**

Bases: Generic[A]

**__init__**(*project*, *analysis_cls*)

**Parameters**

- **project** (Project)
- **analysis_cls** (type*[A]*)

**prep**(*fail_fast=None*, *kb=None*, *progress_callback=None*, *show_progressbar=False*)

**Return type**
type[A]

**Parameters**

- **fail_fast** (*bool* | *None*)
- **kb** (KnowledgeBase | *None*)
- **progress_callback** (Callable | *None*)
- **show_progressbar** (*bool*)

class angr.analyses.analysis.**Analysis**

Bases: object

This class represents an analysis on the program.

**Variables**

- **project** (*Project*) – The project for this analysis.
- **kb** (KnowledgeBase) – The knowledgebase object.
- **_progress_callback** (Callable | None) – A callback function for receiving the progress of this analysis. It only takes one argument, which is a float number from 0.0 to 100.0 indicating the current progress.
- **_show_progressbar** (*bool*) – If a progressbar should be shown during the analysis. It's independent from _progress_callback.
- **_progressbar** (*progress.Progress*) – The progress bar object.

**project:** *Project*

**kb:** *KnowledgeBase*

errors: list[*AnalysisLogEntry*] = []

named_errors: defaultdict[str, list[*AnalysisLogEntry*]] = {}

log: list

property ram_usage: float

Return the current RAM usage of the Python process, in bytes. The value is updated at most once per second.

angr.analyses.analysis.**register_analysis**(*cls*, *name*)

### 10.3.2 angr.analyses.backward_slice

class angr.analyses.backward_slice.**BackwardSlice**

Bases: *Analysis*

Represents a backward slice of the program.

**__init__**(*cfg*, *cdg*, *ddg*, *targets=None*, *cfg_node=None*, *stmt_id=None*, *control_flow_slice=False*, *same_function=False*, *no_construct=False*)

Create a backward slice from a specific statement based on provided control flow graph (CFG), control dependence graph (CDG), and data dependence graph (DDG).

The data dependence graph can be either CFG-based, or Value-set analysis based. A CFG-based DDG is much faster to generate, but it only reflects those states while generating the CFG, and it is neither sound nor accurate. The VSA based DDG (called VSA_DDG) is based on static analysis, which gives you a much better result.

**Parameters**

- **cfg** – The control flow graph.
- **cdg** – The control dependence graph.
- **ddg** – The data dependence graph.
- **targets** – A list of "target" that specify targets of the backward slices. Each target can be a tuple in form of (cfg_node, stmt_idx), or a CodeLocation instance.
- **cfg_node** – Deprecated. The target CFGNode to reach. It should exist in the CFG.
- **stmt_id** – Deprecated. The target statement to reach.
- **control_flow_slice** – True/False, indicates whether we should slice only based on CFG. Sometimes when acquiring DDG is difficult or impossible, you can just create a slice on your CFG. Well, if you don't even have a CFG, then…
- **no_construct** – Only used for testing and debugging to easily create a BackwardSlice object.

**dbg_repr**(*max_display=10*)

Debugging output of this slice.

**Parameters**
**max_display** – The maximum number of SimRun slices to show.

**Returns**
A string representation.

**dbg_repr_run**(*run_addr*)

Debugging output of a single SimRun slice.

**Parameters**
**run_addr** – Address of the SimRun.

**Returns**
A string representation.

**annotated_cfg**(*start_point=None*)

Returns an AnnotatedCFG based on slicing result.

**is_taint_related_to_ip**(*simrun_addr*, *stmt_idx*, *taint_type*, *simrun_whitelist=None*)

Query in taint graph to check if a specific taint will taint the IP in the future or not. The taint is specified with the tuple (simrun_addr, stmt_idx, taint_type).

**Parameters**

- **simrun_addr** – Address of the SimRun.
- **stmt_idx** – Statement ID.
- **taint_type** – Type of the taint, might be one of the following: 'reg', 'tmp', 'mem'.
- **simrun_whitelist** – A list of SimRun addresses that are whitelisted, i.e. the tainted exit will be ignored if it is in those SimRuns.

**Returns**
True/False

**is_taint_impacting_stack_pointers**(*simrun_addr*, *stmt_idx*, *taint_type*, *simrun_whitelist=None*)

Query in taint graph to check if a specific taint will taint the stack pointer in the future or not. The taint is specified with the tuple (simrun_addr, stmt_idx, taint_type).

**Parameters**

- **simrun_addr** – Address of the SimRun.
- **stmt_idx** – Statement ID.
- **taint_type** – Type of the taint, might be one of the following: 'reg', 'tmp', 'mem'.
- **simrun_whitelist** – A list of SimRun addresses that are whitelisted.

**Returns**
True/False.

### 10.3.3 angr.analyses.binary_optimizer

**class** angr.analyses.binary_optimizer.**ConstantPropagation**

Bases: object

**__init__**(*constant*, *constant_assignment_loc*, *constant_consuming_loc*)

**class** angr.analyses.binary_optimizer.**RedundantStackVariable**

Bases: object

**__init__**(*argument*, *stack_variable*, *stack_variable_consuming_locs*)

**class** angr.analyses.binary_optimizer.**RegisterReallocation**

Bases: object

__init__(*stack_variable*, *register_variable*, *stack_variable_sources*, *stack_variable_consumers*, *prologue_addr*, *prologue_size*, *epilogue_addr*, *epilogue_size*)

Constructor.

**Parameters**

- **stack_variable** (SimStackVariable)
- **register_variable** (SimRegisterVariable)
- **stack_variable_sources** (*list*)
- **stack_variable_consumers** (*list*)
- **prologue_addr** (*int*)
- **prologue_size** (*int*)
- **epilogue_addr** (*int*)
- **epilogue_size** (*int*)

class angr.analyses.binary_optimizer.**DeadAssignment**

Bases: object

__init__(*pv*)

Constructor.

**Parameters**
**pv** (angr.analyses.ddg.ProgramVariable) – The assignment to remove.

class angr.analyses.binary_optimizer.**BinaryOptimizer**

Bases: *Analysis*

This is a collection of binary optimization techniques we used in Mechanical Phish during the finals of Cyber Grand Challenge. It focuses on dealing with some serious speed-impacting code constructs, and *sort of* worked on *some* CGC binaries compiled with O0. Use this analysis as a reference of how to use data dependency graph and such.

There is no guarantee that BinaryOptimizer will ever work on non-CGC binaries. Feel free to give us PR or MR, but please *do not* ask for support of non-CGC binaries.

**BLOCKS_THRESHOLD = 500**

__init__(*cfg*, *techniques*)

**Parameters**
**techniques** (*set[str]*)

**optimize**()

### 10.3.4 angr.analyses.bindiff

exception angr.analyses.bindiff.**UnmatchedStatementsException**

Bases: Exception

class angr.analyses.bindiff.**Difference**

Bases: object

__init__(*diff_type*, *value_a*, *value_b*)

class angr.analyses.bindiff.**ConstantChange**

Bases: object

**__init__**(*offset*, *value_a*, *value_b*)

angr.analyses.bindiff.**differing_constants**(*block_a*, *block_b*)

Compares two basic blocks and finds all the constants that differ from the first block to the second.

**Parameters**

- **block_a** – The first block to compare.
- **block_b** – The second block to compare.

**Returns**

Returns a list of differing constants in the form of ConstantChange, which has the offset in the block and the respective constants.

angr.analyses.bindiff.**compare_statement_dict**(*statement_1*, *statement_2*)

class angr.analyses.bindiff.**NormalizedBlock**

Bases: object

**__init__**(*block*, *function*)

class angr.analyses.bindiff.**NormalizedFunction**

Bases: object

**__init__**(*function*)

**Parameters**

**function** (Function)

class angr.analyses.bindiff.**FunctionDiff**

Bases: object

This class computes the a diff between two functions.

**__init__**(*function_a*, *function_b*, *bindiff=None*)

**Parameters**

- **function_a** (*Function*) – The first angr Function object to diff.
- **function_b** (*Function*) – The second angr Function object.
- **bindiff** – An optional Bindiff object. Used for some extra normalization during basic block comparison.

**property probably_identical**

Whether or not these two functions are identical.

**Type**

returns

**property identical_blocks**

A list of block matches which appear to be identical

**Type**

returns

property differing_blocks

A list of block matches which appear to differ

**Type**
returns

property blocks_with_differing_constants

A list of block matches which appear to differ

**Type**
return

property block_matches

property unmatched_blocks

static get_normalized_block(*addr*, *function*)

**Parameters**

- **addr** – Where to start the normalized block.
- **function** – A function containing the block address.

**Returns**
A normalized basic block.

block_similarity(*block_a*, *block_b*)

**Parameters**

- **block_a** – The first block address.
- **block_b** – The second block address.

**Returns**
The similarity of the basic blocks, normalized for the base address of the block and function call addresses.

blocks_probably_identical(*block_a*, *block_b*, *check_constants=False*)

**Parameters**

- **block_a** – The first block address.
- **block_b** – The second block address.
- **check_constants** – Whether or not to require matching constants in blocks.

**Returns**
Whether or not the blocks appear to be identical.

class angr.analyses.bindiff.**BinDiff**

Bases: *Analysis*

This class computes the a diff between two binaries represented by angr Projects

__init__(*other_project*, *cfg_a=None*, *cfg_b=None*)

**Parameters**
**other_project** – The second project to diff

**functions_probably_identical**(*func_a_addr*, *func_b_addr*, *check_consts=False*)

Compare two functions and return True if they appear identical.

**Parameters**

- **func_a_addr** – The address of the first function (in the first binary).
- **func_b_addr** – The address of the second function (in the second binary).

**Returns**

Whether or not the functions appear to be identical.

**property identical_functions**

A list of function matches that appear to be identical

**Type**

returns

**property differing_functions**

A list of function matches that appear to differ

**Type**

returns

**differing_functions_with_consts**()

**Returns**

A list of function matches that appear to differ including just by constants

**property differing_blocks**

A list of block matches that appear to differ

**Type**

returns

**property identical_blocks**

return A list of all block matches that appear to be identical

**property blocks_with_differing_constants**

A dict of block matches with differing constants to the tuple of constants

**Type**

return

**property unmatched_functions**

**get_function_diff**(*function_addr_a*, *function_addr_b*)

**Parameters**

- **function_addr_a** – The address of the first function (in the first binary)
- **function_addr_b** – The address of the second function (in the second binary)

**Returns**

the FunctionDiff of the two functions

### 10.3.5 angr.analyses.boyscout

class angr.analyses.boyscout.**BoyScout**

Bases: *Analysis*

Try to determine the architecture and endieness of a binary blob

**__init__**(*cookiesize=1*)

### 10.3.6 angr.analyses.callee_cleanup_finder

class angr.analyses.callee_cleanup_finder.**CalleeCleanupFinder**

Bases: *Analysis*

**__init__**(*starts=None*, *hook_all=False*)

**analyze**(*addr*)

### 10.3.7 angr.analyses.calling_convention

class angr.analyses.calling_convention.**CallingConventionAnalysis**

Bases: *Analysis*

Analyze the calling convention of a function and guess a probable prototype.

The calling convention of a function can be inferred at both its call sites and the function itself. At call sites, we consider all register and stack variables that are not alive after the function call as parameters to this function. In the function itself, we consider all register and stack variables that are read but without initialization as parameters. Then we synthesize the information from both locations and make a reasonable inference of calling convention of this function.

**Variables**

- **_function** – The function to recover calling convention for.
- **_variable_manager** – A handy accessor to the variable manager.
- **_cfg** – A reference of the CFGModel of the current binary. It is used to discover call sites of the current function in order to perform analysis at call sites.
- **analyze_callsites** – True if we should analyze all call sites of the current function to determine the calling convention and arguments. This can be time-consuming if there are many call sites to analyze.
- **cc** (*SimCC* | None) – The recovered calling convention for the function.
- **_collect_facts** – True if we should run FunctionFactCollector to collect input arguments and return value size. False if input arguments and return value size are provided by the user.

**__init__**(*func*, *cfg=None*, *analyze_callsites=False*, *caller_func_addr=None*, *callsite_block_addr=None*, *callsite_insn_addr=None*, *func_graph=None*, *input_args=None*, *retval_size=None*, *extra_pop=None*, *collect_facts=False*, *collect_facts_arg_uses=False*, *collect_facts_arg_passthru=False*, *flavor=None*)

**Parameters**

- **flavor** (str | None) – The decompilation flavor whose callee prototypes are consulted (None: the default flavor).
- **func** (*Function* | *int* | *str* | *None*)
- **cfg** (*CFGModel* | *None*)
- **analyze_callsites** (*bool*)

- **caller_func_addr** (*int | None*)
- **callsite_block_addr** (*int | None*)
- **callsite_insn_addr** (*int | None*)
- **func_graph** (*networkx.DiGraph | None*)
- **input_args** (*list[SimRegArg | SimStackArg] | None*)
- **retval_size** (*int | None*)
- **extra_pop** (*int | None*)
- **collect_facts** (*bool*)
- **collect_facts_arg_uses** (*bool*)
- **collect_facts_arg_passthru** (*bool*)

**has_va_xmm_save_area_amd64**(*func*)

Detect the va_start prologue idiom that spills xmm0-xmm7 into the register save area (`test al, al; je ...; movaps [base+disp+16*i], xmm_i` for i in 0..7).

**Return type**
bool

**Parameters**
**func** (Function)

**is_va_start_amd64**(*func*)

**Return type**
tuple[bool, int | None]

**Parameters**
**func** (Function)

**class** angr.analyses.calling_convention.**FactCollector**

Bases: *Analysis*

An extremely fast analysis that extracts necessary facts of a function for CallingConventionAnalysis to make decision on the calling convention and prototype of a function.

**__init__**(*func*, *max_depth=100*, *track_arg_uses=False*, *track_arg_passthru=False*, *flavor=None*)

**Parameters**

- **func** (Function)
- **max_depth** (*int*)
- **track_arg_uses** (*bool*)
- **track_arg_passthru** (*bool*)
- **flavor** (*str | None*)

**callsites**: dict[int, tuple[*Function*, list[*FactData*]]]

callsite -> (callee, values passed to each argument of the callee's prototype, in prototype order)

**pushed_arg_callsites**: dict[int, tuple[*Function*, list[*FactData*]]]

callsite -> (callee without a usable prototype, values pushed to the outgoing stack). positions are not prototype indices.

**input_args:** list[*SimRegArg* | *SimStackArg*] | None

**unused_args:** list[*SimRegArg*]

**retval_size:** int | None

**retval_incidental:** bool

True when every endpoint's write to the return register looks like a leftover rather than a return value: the value written is consumed again in the same block (stored, tested, passed on) after the write. A void function whose last instruction happens to load into rax looks exactly like a getter from the outside; this is the one local hint that it is not, and CallingConventionAnalysis only lets call-site evidence demote a prototype to void when it is set.

**pointer_arg_derefs:** defaultdict[*FactData*, int]

**pointer_arg_deref_sizes:** dict[*FactData*, int]

**retval_arg:** *SimRegArg* | None

the input argument register whose entry value is in the return register at every return site (an sret-style hidden result pointer, strcpy's dest, ...), or None

**extra_pop:** int | None

Number of bytes the callee pops after the return address on the stack, or None if we cannot determine.

**MAX_CONTINUATION_DEPTH = 3**

**MAX_CALLER_SITES = 16**

### Submodules

*calling_convention*
*fact_collector*
*utils*

### angr.analyses.calling_convention.calling_convention

**class** angr.analyses.calling_convention.calling_convention.**CallSiteFact**

Bases: object

Store facts about each call site.

**__init__**(*return_value_used*)

**class** angr.analyses.calling_convention.calling_convention.**UpdateArgumentsOption**

Bases: object

Enums for controlling the argument updating behavior in _adjust_cc.

**DoNotUpdate = 0**

**AlwaysUpdate = 1**

**UpdateWhenCCHasNoArgs = 2**

**class** angr.analyses.calling_convention.calling_convention.**CallingConventionAnalysis**

Bases: *Analysis*

Analyze the calling convention of a function and guess a probable prototype.

The calling convention of a function can be inferred at both its call sites and the function itself. At call sites, we consider all register and stack variables that are not alive after the function call as parameters to this function. In the function itself, we consider all register and stack variables that are read but without initialization as parameters. Then we synthesize the information from both locations and make a reasonable inference of calling convention of this function.

**Variables**

- **_function** – The function to recover calling convention for.
- **_variable_manager** – A handy accessor to the variable manager.
- **_cfg** – A reference of the CFGModel of the current binary. It is used to discover call sites of the current function in order to perform analysis at call sites.
- **analyze_callsites** – True if we should analyze all call sites of the current function to determine the calling convention and arguments. This can be time-consuming if there are many call sites to analyze.
- **cc** (*SimCC* | None) – The recovered calling convention for the function.
- **_collect_facts** – True if we should run FunctionFactCollector to collect input arguments and return value size. False if input arguments and return value size are provided by the user.

**__init__**(*func*, *cfg=None*, *analyze_callsites=False*, *caller_func_addr=None*, *callsite_block_addr=None*, *callsite_insn_addr=None*, *func_graph=None*, *input_args=None*, *retval_size=None*, *extra_pop=None*, *collect_facts=False*, *collect_facts_arg_uses=False*, *collect_facts_arg_passthru=False*, *flavor=None*)

**has_va_xmm_save_area_amd64**(*func*)

Detect the va_start prologue idiom that spills xmm0-xmm7 into the register save area (`test al, al; je ...; movaps [base+disp+16*i], xmm_i` for i in 0..7).

**Return type**
bool

**Parameters**
**func** (Function)

**is_va_start_amd64**(*func*)

**Return type**
tuple[bool, int | None]

**Parameters**
**func** (Function)

### angr.analyses.calling_convention.fact_collector

**type** angr.analyses.calling_convention.fact_collector.**FactData** = tuple[int, int, int] | None

**class** angr.analyses.calling_convention.fact_collector.**FactCollectorState**

Bases: object

The abstract state for FactCollector.

**__init__**()

**tmps:** dict[int, *FactData*]

**simple_stack:** dict[int, *FactData*]

**simple_regs:** dict[int, *FactData*]

**ins_addr**

**callee_stored_regs:** dict[int, int]

**reg_reads**

**reg_reads_count**

**reg_lane_reads:** dict[int, int]

widest scalar (<= 8-byte) lane consumed from an FP argument register, directly or through a full-register copy; it narrows a vector-wide read (movaps xmm6, xmm2) to the width the function actually uses

**reg_writes:** set[int]

**stack_reads**

**stack_reads_fp**

**stack_writes:** set[int]

**pointer_arg_derefs:** defaultdict[*FactData*, int]

**pointer_arg_deref_sizes: dict[*FactData*, int]**

widest access through each pointer argument, in bytes

**sp_value**

**bp_value**

**register_read**(*offset*, *size_in_bytes*)

**Parameters**

- **offset** (*int*)
- **size_in_bytes** (*int*)

**register_entry_read**(*offset*, *size_in_bytes*)

A read of the register's function-entry value, already known to precede any write to it.

**Parameters**

- **offset** (*int*)
- **size_in_bytes** (*int*)

**register_lane_read**(*offset*, *size_in_bytes*)

**Parameters**

- **offset** (*int*)
- **size_in_bytes** (*int*)

**register_read_undo**(*offset*)

**Return type**
None

**Parameters**
**offset** (*int*)

**register_written**(*offset*, *size_in_bytes*)

**Parameters**

- **offset** (*int*)
- **size_in_bytes** (*int*)

**stack_read**(*offset*, *size_in_bytes*, *fp=False*)

**Parameters**

- **offset** (*int*)
- **size_in_bytes** (*int*)
- **fp** (*bool*)

**stack_written**(*offset*, *size_int_bytes*)

**Parameters**

- **offset** (*int*)
- **size_int_bytes** (*int*)

**copy**(*with_tmps=True*)

**Return type**
*FactCollectorState*

**Parameters**
**with_tmps** (*bool*)

**class** angr.analyses.calling_convention.fact_collector.**SimEngineFactCollectorVEX**

Bases: *SimEngineNostmtVEX*[*FactCollectorState*, , None], *SimEngineLight*[*FactCollectorState*, , *Block*, None]

The engine for FactCollector.

**__init__**(*project*, *bp_as_gpr*, *track_arg_uses*, *seen_reg_uses*, *seen_reg_pushes*)

**Parameters**

- **bp_as_gpr** (*bool*)
- **track_arg_uses** (*bool*)
- **seen_reg_uses** (*defaultdict[int, int]*)
- **seen_reg_pushes** (*defaultdict[int, int]*)

**seen_reg_pushes**

spills or stack-padding pushes

**Type**
stores of a register's entry value to the stack (push reg)

**process**(*state*, *, *block=None*, *whitelist=None*, ***kwargs*)

**class** angr.analyses.calling_convention.fact_collector.**FactCollector**

Bases: *Analysis*

An extremely fast analysis that extracts necessary facts of a function for CallingConventionAnalysis to make decision on the calling convention and prototype of a function.

**__init__**(*func*, *max_depth=100*, *track_arg_uses=False*, *track_arg_passthru=False*, *flavor=None*)

**Parameters**

- **func** (Function)
- **max_depth** (*int*)
- **track_arg_uses** (*bool*)
- **track_arg_passthru** (*bool*)
- **flavor** (*str | None*)

**callsites:** dict[int, tuple[*Function*, list[*FactData*]]]

callsite -> (callee, values passed to each argument of the callee's prototype, in prototype order)

**pushed_arg_callsites:** dict[int, tuple[*Function*, list[*FactData*]]]

callsite -> (callee without a usable prototype, values pushed to the outgoing stack). positions are not prototype indices.

**input_args:** list[*SimRegArg* | *SimStackArg*] | None

**unused_args:** list[*SimRegArg*]

**retval_size:** int | None

**retval_incidental:** bool

True when every endpoint's write to the return register looks like a leftover rather than a return value: the value written is consumed again in the same block (stored, tested, passed on) after the write. A void function whose last instruction happens to load into rax looks exactly like a getter from the outside; this is the one local hint that it is not, and CallingConventionAnalysis only lets call-site evidence demote a prototype to void when it is set.

**pointer_arg_derefs:** defaultdict[*FactData*, int]

**pointer_arg_deref_sizes:** dict[*FactData*, int]

**retval_arg:** *SimRegArg* | None

the input argument register whose entry value is in the return register at every return site (an sret-style hidden result pointer, strcpy's dest, ...), or None

**extra_pop:** int | None

Number of bytes the callee pops after the return address on the stack, or None if we cannot determine.

**MAX_CONTINUATION_DEPTH = 3**

**MAX_CALLER_SITES = 16**

### angr.analyses.calling_convention.utils

angr.analyses.calling_convention.utils.**is_sane_register_variable**(*arch*, *reg_offset*, *reg_size*, *def_cc=None*)

Filters all registers that are surly not members of function arguments. This can be seen as a workaround, since VariableRecoveryFast sometimes gives input variables of cc_ndep (which is a VEX-specific register) :-(

**Parameters**

- **reg_offset** (int) – The register offset.
- **reg_size** (int) – The register size.
- **arch** (*Arch*)
- **def_cc** (SimCC | type[SimCC] | *None*)

**Returns**

True if it is an acceptable function argument, False otherwise.

**Return type**

bool

angr.analyses.calling_convention.utils.**reg_arg_from_span**(*arch*, *offset*, *size*)

Build a register argument for a read of `size` bytes at `offset`.

SimRegArg is keyed by register name. A read that starts at an unnamed offset (e.g., movmskpd's GET:I32 at xmm0+4) widens to the smallest named register covering it instead of taking archinfo's stringified-offset fallback name.

**Return type**

*SimRegArg*

**Parameters**

- **arch** (*Arch*)
- **offset** (*int*)

- **size** (*int*)

angr.analyses.calling_convention.utils.**fold_fp_lane_reads**(*arch*, *reg_reads*, *def_cc*)

On AMD64, fold reads of upper lanes of an FP argument register (movmskps reads xmm0+4/+8/+12) into the register itself: one xmm register holds one argument. When the low lane is read, its width is the argument width; otherwise the folded read covers the lanes up to the scalar width (8 bytes).

**Return type**
dict[int, int]

**Parameters**

- **arch** (*Arch*)
- **reg_reads** (*dict[int, int]*)
- **def_cc** (SimCC | type[SimCC] | *None*)

angr.analyses.calling_convention.utils.**merge_overlapping_register_spans**(*arch*, *spans*)

Merge register reads that belong to the same base register into one span per base register.

The merged span is the smallest named register starting at the base register that covers every read (e.g., reads of `ch` and `cx` become `cx`). When no register of the covering size exists, the widest read is kept. Floating-point and vector registers are left alone: their sub-registers hold separate arguments (e.g., `s0` and `s1` in `d0` on ARM hard-float).

**Parameters**

- **arch** (Arch) – The architecture.
- **spans** (Iterable[tuple[int, int]]) – Register reads as (offset, size) tuples.

**Return type**
list[tuple[int, int]]

**Returns**
Merged (offset, size) tuples, sorted by offset.

### 10.3.8 angr.analyses.cdg

**class** angr.analyses.cdg.**CDG**

Bases: *Analysis*

Implements a control dependence graph.

**__init__**(*cfg*, *start=None*, *no_construct=False*)

Constructor.

**Parameters**

- **cfg** – The control flow graph upon which this control dependence graph will build
- **start** – The starting point to begin constructing the control dependence graph
- **no_construct** – Skip the construction step. Only used in unit-testing.

**property graph**

**get_post_dominators**()

Return the post-dom tree

**get_dependants**(*run*)

Return a list of nodes that are control dependent on the given node in the control dependence graph

**get_guardians**(*run*)

Return a list of nodes on whom the specific node is control dependent in the control dependence graph

### 10.3.9 angr.analyses.cfg

**class** angr.analyses.cfg.**CFG**

Bases: *CFGFast*

tl;dr: CFG is just a wrapper around CFGFast for compatibility issues. It will be fully replaced by CFGFast in future releases. Feel free to use CFG if you intend to use CFGFast. Please use CFGEmulated if you *have to* use the old, slow, dynamically-generated version of CFG.

For multiple historical reasons, angr's CFG is accurate but slow, which does not meet what most people expect. We developed CFGFast for light-speed CFG recovery, and renamed the old CFG class to CFGEmulated. For compatibility concerns, CFG was kept as an alias to CFGEmulated.

However, so many new users of angr would load up a binary and generate a CFG immediately after running "pip install angr", and draw the conclusion that "angr's CFG is so slow - angr must be unusable!" Therefore, we made the hard decision: CFG will be an alias to CFGFast, instead of CFGEmulated.

To ease the transition of your existing code and script, the following changes are made:

- A CFG class, which is a sub class of CFGFast, is created.
- You will see both a warning message printed out to stderr and an exception raised by angr if you are passing CFG any parameter that only CFGEmulated supports. This exception is not a sub class of AngrError, so you wouldn't capture it with your old code by mistake.
- In the near future, this wrapper class will be removed completely, and CFG will be a simple alias to CFGFast.

We expect most interfaces are the same between CFGFast and CFGEmulated. Apparently some functionalities (like context-sensitivity, and state keeping) only exist in CFGEmulated, which is when you want to use CFGEmulated instead.

**class** angr.analyses.cfg.**CFBlanket**

Bases: *Analysis*

A Control-Flow Blanket is a representation for storing all instructions, data entries, and bytes of a full program.

Region types: - section - segment - extern - tls - kernel

**__init__**(*exclude_region_types=None*, *on_object_added=None*, *on_object_removed=None*)

**Parameters**

- **on_object_added** (Callable[[int, Any], None] | None) – Callable with parameters (addr, obj) called after an object is added to the blanket.
- **on_object_removed** (Callable[[int, Any], None] | None) – Callable with parameters (addr, obj) called after an object is removed from the blanket.
- **exclude_region_types** (*set[str] | None*)

**property regions**

Return all memory regions.

**floor_addr**(*addr*)

**Return type**
int

**Parameters**
**addr** (*int*)

floor_item(*addr*)

**Return type**
tuple[int, Any]

**Parameters**
**addr** (*int*)

floor_items(*addr=None*, *reverse=False*)

ceiling_addr(*addr*)

**Return type**
int

**Parameters**
**addr** (*int*)

ceiling_item(*addr*)

**Return type**
tuple[int, Any]

**Parameters**
**addr** (*int*)

ceiling_items(*addr=None*, *reverse=False*, *include_first=True*)

add_obj(*addr*, *obj*)

Add an object *obj* to the blanket at the specified address *addr*, keeping the blanket non-overlapping: existing objects that overlap [addr, addr + obj.size) are removed or trimmed, and the trimmed-off remainders are re-inserted. Objects without an integer size are stored as zero-span entries and never cause trimming.

remove_obj(*addr*, *fill=True*)

Remove the object at *addr* from the blanket. When *fill* is set (the default), the removed object's span is re-filled with an Unknown region so that the blanket remains a total cover of the mapped address space. Removing a missing address is a no-op.

**Returns**
The removed object, or None if no object exists at *addr*.

**Parameters**
**fill** (*bool*)

add_function(*func*)

Add a function *func* and all blocks of this function to the blanket.

dbg_repr()

The debugging representation of this CFBlanket.

**Returns**
The debugging representation of this CFBlanket.

**Return type**
str

class angr.analyses.cfg.**CFGArchOptions**

Bases: object

Stores architecture-specific options and settings, as well as the detailed explanation of those options and settings.

Suppose *ao* is the CFGArchOptions object, and there is an option called *ret_jumpkind_heuristics*, you can access it by *ao.ret_jumpkind_heuristics* and set its value via *ao.ret_jumpkind_heuristics = True*

**Variables**

- **OPTIONS** (*dict*) – A dict of all default options for different architectures.
- **arch** (*archinfo.Arch*) – The architecture object.
- **_options** (*dict*) – Values of all CFG options that are specific to the current architecture.

```
OPTIONS = {'ARMCortexM': {'has_arm_code': (<class 'bool'>, False),
'pattern_match_ifuncs': (<class 'bool'>, True), 'ret_jumpkind_heuristics': (<class
'bool'>, True), 'switch_mode_on_nodecode': (<class 'bool'>, False)}, 'ARMEL':
{'has_arm_code': (<class 'bool'>, True), 'pattern_match_ifuncs': (<class 'bool'>,
True), 'ret_jumpkind_heuristics': (<class 'bool'>, True),
'switch_mode_on_nodecode': (<class 'bool'>, True)}, 'ARMHF': {'has_arm_code':
(<class 'bool'>, True), 'pattern_match_ifuncs': (<class 'bool'>, True),
'ret_jumpkind_heuristics': (<class 'bool'>, True), 'switch_mode_on_nodecode':
(<class 'bool'>, True)}}
```

**__init__**(*arch*, ***options*)

Constructor.

**Parameters**

- **arch** (*archinfo.Arch*) – The architecture instance.
- **options** (*dict*) – Architecture-specific options, which will be used to initialize this object.

```
arch = None
```

**class** angr.analyses.cfg.**CFGBase**

Bases: *Analysis*

The base class for control flow graphs.

```
tag: str = None
```

```
addr_type: Literal['int', 'block_id', 'soot'] = None
```

**__init__**(*sort*, *context_sensitivity_level*, *normalize=False*, *binary=None*, *objects=None*, *regions=None*, *exclude_sparse_regions=True*, *skip_specific_regions=True*, *force_segment=False*, *base_state=None*, *resolve_indirect_jumps=True*, *indirect_jump_resolvers=None*, *indirect_jump_target_limit=100000*, *detect_tail_calls=False*, *low_priority=False*, *skip_unmapped_addrs=True*, *sp_tracking_track_memory=True*, *model=None*)

**Parameters**

- **sort** (*str*) – 'fast' or 'emulated'.
- **context_sensitivity_level** (*int*) – The level of context-sensitivity of this CFG (see documentation for further details). It ranges from 0 to infinity.
- **normalize** (*bool*) – Whether the CFG as well as all Function graphs should be normalized.
- **binary** (*cle.backends.Backend*) – The binary to recover CFG on. By default, the main binary is used.
- **objects** – A list of objects to recover the CFG on. By default, it will recover the CFG of all loaded objects.
- **regions** (*iterable*) – A list of tuples in the form of (start address, end address) describing memory regions that the CFG should cover.

- **force_segment** (*bool*) – Force CFGFast to rely on binary segments instead of sections.
- **base_state** (*angr.SimState*) – A state to use as a backer for all memory loads.
- **resolve_indirect_jumps** (*bool*) – Whether to try to resolve indirect jumps. This is necessary to resolve jump targets from jump tables, etc.
- **indirect_jump_resolvers** (*list*) – A custom list of indirect jump resolvers. If this list is None or empty, default indirect jump resolvers specific to this architecture and binary types will be loaded.
- **indirect_jump_target_limit** (*int*) – Maximum indirect jump targets to be recovered.
- **skip_unmapped_addrs** – Ignore all branches into unmapped regions. True by default. You may want to set it to False if you are analyzing manually patched binaries or malware samples.
- **detect_tail_calls** (*bool*) – Aggressive tail-call optimization detection. This option is only respected in make_functions().
- **sp_tracking_track_memory** (*bool*) – Whether or not to track memory writes if tracking the stack pointer. This increases the accuracy of stack pointer tracking, especially for architectures without a base pointer. Only used if detect_tail_calls is enabled.
- **model** (*None or CFGModel*) – The CFGModel instance to write to. A new CFGModel instance will be created and registered with the knowledge base if *model* is None.

**Returns**
None

**indirect_jumps:** `dict[int, IndirectJump]`

**property model:** *CFGModel*

Get the CFGModel instance. :return: The CFGModel instance that this analysis currently uses.

**property normalized**

**property context_sensitivity_level**

**property functions**

A reference to the FunctionManager in the current knowledge base.

**Returns**
FunctionManager with all functions

**Return type**
angr.knowledge_plugins.FunctionManager

**property regions:** `list[tuple[int, int]]`

The memory regions that this analysis covers. An empty list means it had nothing to scan.

**Returns**
A sorted list of (start address, end address) tuples.

**make_copy**(*copy_to*)

Copy self attributes to the new object.

**Parameters**
**copy_to** (CFGBase) – The target to copy to.

**Returns**
None

**copy**()

**output**()

**generate_index**()

Generate an index of all nodes in the graph in order to speed up get_any_node() with anyaddr=True.

**Returns**
None

**get_loop_back_edges**()

**property graph:** *SpillingCFG*

**remove_edge**(*block_from*, *block_to*)

**is_thumb_addr**(*addr*)

**record_memory_data_addr**(*addr*)

Record the address of a newly added memory data object.

**Return type**
None

**Parameters**
**addr** (*int*)

**reset_memory_data_addrs**()

Reset the set of addresses of newly added memory data objects.

**Return type**
None

**normalize**()

Normalize the CFG, making sure that there are no overlapping basic blocks.

Note that this method will not alter transition graphs of each function in self.kb.functions. You may call normalize() on each Function object to normalize their transition graphs.

**Returns**
None

**mark_function_alignments**()

Find all potential function alignments and mark them.

Note that it is not always correct to simply remove them, because these functions may not be actual alignments but part of an actual function, and is incorrectly marked as an individual function because of failures in resolving indirect jumps. An example is in the test binary `x86_64/dir_gcc_-O0` 0x40541d (indirect jump at 0x4051b0). If the indirect jump cannot be correctly resolved, removing function 0x40541d will cause a missing label failure in reassembler.

**Returns**
None

**make_functions**()

Revisit the entire control flow graph, create Function instances accordingly, and correctly put blocks into each function.

Although Function objects are created during the CFG recovery, they are neither sound nor accurate. With a pre-constructed CFG, this method rebuilds all functions bearing the following rules:

- A block may only belong to one function.

- Small functions lying inside the startpoint and the endpoint of another function will be merged with the other function
- Tail call optimizations are detected.
- PLT stubs are aligned by 16.

**Returns**
None

class angr.analyses.cfg.**CFGEmulated**

Bases: *ForwardAnalysis*, *CFGBase*

This class represents a control-flow graph.

**tag:** `str = 'CFGEmulated'`

**addr_type:** `Literal['int', 'block_id', 'soot'] = 'block_id'`

**__init__**(*context_sensitivity_level=1*, *start=None*, *avoid_runs=None*, *enable_function_hints=False*, *call_depth=None*, *call_tracing_filter=None*, *initial_state=None*, *starts=None*, *keep_state=False*, *indirect_jump_target_limit=100000*, *resolve_indirect_jumps=True*, *enable_advanced_backward_slicing=False*, *enable_symbolic_back_traversal=False*, *indirect_jump_resolvers=None*, *additional_edges=None*, *no_construct=False*, *normalize=False*, *max_iterations=1*, *address_whitelist=None*, *base_graph=None*, *iropt_level=None*, *max_steps=None*, *state_add_options=None*, *state_remove_options=None*, *model=None*)

All parameters are optional.

**Parameters**

- **context_sensitivity_level** – The level of context-sensitivity of this CFG (see documentation for further details). It ranges from 0 to infinity. Default 1.
- **avoid_runs** – A list of runs to avoid.
- **enable_function_hints** – Whether to use function hints (constants that might be used as exit targets) or not.
- **call_depth** – How deep in the call stack to trace.
- **call_tracing_filter** – Filter to apply on a given path and jumpkind to determine if it should be skipped when call_depth is reached.
- **initial_state** – An initial state to use to begin analysis.
- **starts** (*iterable*) – A collection of starting points to begin analysis. It can contain the following three different types of entries: an address specified as an integer, a 2-tuple that includes an integer address and a jumpkind, or a SimState instance. Unsupported entries in starts will lead to an AngrCFGError being raised.
- **keep_state** – Whether to keep the SimStates for each CFGNode.
- **resolve_indirect_jumps** – Whether to enable the indirect jump resolvers for resolving indirect jumps
- **enable_advanced_backward_slicing** – Whether to enable an intensive technique for resolving indirect jumps
- **enable_symbolic_back_traversal** – Whether to enable an intensive technique for resolving indirect jumps

- **indirect_jump_resolvers** (*list*) – A custom list of indirect jump resolvers. If this list is None or empty, default indirect jump resolvers specific to this architecture and binary types will be loaded.
- **additional_edges** – A dict mapping addresses of basic blocks to addresses of successors to manually include and analyze forward from.
- **no_construct** (*bool*) – Skip the construction procedure. Only used in unit-testing.
- **normalize** (*bool*) – If the CFG as well as all Function graphs should be normalized or not.
- **max_iterations** (*int*) – The maximum number of iterations that each basic block should be "executed". 1 by default. Larger numbers of iterations are usually required for complex analyses like loop analysis.
- **address_whitelist** (*iterable*) – A list of allowed addresses. Any basic blocks outside of this collection of addresses will be ignored.
- **base_graph** (*networkx.DiGraph*) – A basic control flow graph to follow. Each node inside this graph must have the following properties: *addr* and *size*. CFG recovery will strictly follow nodes and edges shown in the graph, and discard any control flow that does not follow an existing edge in the base graph. For example, you can pass in a Function local transition graph as the base graph, and CFGEmulated will traverse nodes and edges and extract useful information.
- **iropt_level** (*int*) – The optimization level of VEX IR (0, 1, 2). The default level will be used if *iropt_level* is None.
- **max_steps** (*int*) – The maximum number of basic blocks to recover forthe longest path from each start before pausing the recovery procedure.
- **state_add_options** – State options that will be added to the initial state.
- **state_remove_options** – State options that will be removed from the initial state.

**copy**()

Make a copy of the CFG.

**Return type**
*CFGEmulated*

**Returns**
A copy of the CFG instance.

**resume**(*starts=None*, *max_steps=None*)

Resume a paused or terminated control flow graph recovery.

**Parameters**

- **starts** (*iterable*) – A collection of new starts to resume from. If *starts* is None, we will resume CFG recovery from where it was paused before.
- **max_steps** (*int*) – The maximum number of blocks on the longest path starting from each start before pausing the recovery.

**Returns**
None

**remove_cycles**()

Forces graph to become acyclic, removes all loop back edges and edges between overlapped loop headers and their successors.

**downsize**()

Remove saved states from all CFGNodes to reduce memory usage.

**Returns**
None

**unroll_loops**(*max_loop_unrolling_times*)

Unroll loops for each function. The resulting CFG may still contain loops due to recursion, function calls, etc.

**Parameters**
**max_loop_unrolling_times** (*int*) – The maximum iterations of unrolling.

**Returns**
None

**force_unroll_loops**(*max_loop_unrolling_times*)

Unroll loops globally. The resulting CFG does not contain any loop, but this method is slow on large graphs.

**Parameters**
**max_loop_unrolling_times** (*int*) – The maximum iterations of unrolling.

**Returns**
None

**immediate_dominators**(*start*, *target_graph=None*)

Get all immediate dominators of sub graph from given node upwards.

**Parameters**

- **start** (*str*) – id of the node to navigate forwards from.
- **target_graph** (*networkx.classes.digraph.DiGraph*) – graph to analyse, default is self.graph.

**Returns**
each node of graph as index values, with element as respective node's immediate dominator.

**Return type**
dict

**immediate_postdominators**(*end*, *target_graph=None*)

Get all immediate postdominators of sub graph from given node upwards.

**Parameters**

- **start** (*str*) – id of the node to navigate forwards from.
- **target_graph** (*networkx.classes.digraph.DiGraph*) – graph to analyse, default is self.graph.

**Returns**
each node of graph as index values, with element as respective node's immediate dominator.

**Return type**
dict

**remove_fakerets**()

Get rid of fake returns (i.e., Ijk_FakeRet edges) from this CFG

**Returns**
None

**get_topological_order**(*cfg_node*)

Get the topological order of a CFG Node.

**Parameters**
**cfg_node** – A CFGNode instance.

**Returns**
An integer representing its order, or None if the CFGNode does not exist in the graph.

**get_subgraph**(*starting_node*, *block_addresses*)

Get a sub-graph out of a bunch of basic block addresses.

**Parameters**

- **starting_node** (CFGNode) – The beginning of the subgraph
- **block_addresses** (*iterable*) – A collection of block addresses that should be included in the subgraph if there is a path between *starting_node* and a CFGNode with the specified address, and all nodes on the path should also be included in the subgraph.

**Returns**
A new CFG that only contain the specific subgraph.

**Return type**
*CFGEmulated*

**get_function_subgraph**(*start*, *max_call_depth=None*)

Get a sub-graph of a certain function.

**Parameters**

- **start** – The function start. Currently it should be an integer.
- **max_call_depth** – Call depth limit. None indicates no limit.

**Returns**
A CFG instance which is a sub-graph of self.graph

**property context_sensitivity_level**

**property graph:** *SpillingCFG*

**property unresolvables**

Get those SimRuns that have non-resolvable exits.

**Returns**
A set of SimRuns

**Return type**
set

**property deadends**

Get all CFGNodes that has an out-degree of 0

**Returns**
A list of CFGNode instances

**Return type**
list

class angr.analyses.cfg.**CFGFast**

Bases: *ForwardAnalysis*[*CFGNode*, *CFGNode*, *CFGJob*, int, object], *CFGBase*

We find functions inside the given binary, and build a control-flow graph in very fast manners: instead of simulating program executions, keeping track of states, and performing expensive data-flow analysis, CFGFast will only perform light-weight analyses combined with some heuristics, and with some strong assumptions.

In order to identify as many functions as possible, and as accurate as possible, the following operation sequence is followed:

# Active scanning

- If the binary has "function symbols" (TODO: this term is not accurate enough), they are starting points of the code scanning
- If the binary does not have any "function symbol", we will first perform a function prologue scanning on the entire binary, and start from those places that look like function beginnings
- Otherwise, the binary's entry point will be the starting point for scanning

# Passive scanning

- After all active scans are done, we will go through the whole image and scan all code pieces

Due to the nature of those techniques that are used here, a base address is often not required to use this analysis routine. However, with a correct base address, CFG recovery will almost always yield a much better result. A custom analysis, called GirlScout, is specifically made to recover the base address of a binary blob. After the base address is determined, you may want to reload the binary with the new base address by creating a new Project object, and then re-recover the CFG.

**PROLOGUE_SCAN_PADDING = 64**

**PRINTABLES = b'0123456789abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ!"#$%&**
**'()*+,-./:;<=>?@[\\]^_`{|}~ \t\n\r'**

**SPECIAL_THUNKS = {'AMD64':**
**{b'\xe8\x07\x00\x00\x00\xf3\x90\x0f\xae\xe8\xeb\xf9H\x89\x04$\xc3': ('jmp', 'rax'),**
**b'\xe8\x07\x00\x00\x00\xf3\x90\x0f\xae\xe8\xeb\xf9H\x8dd$\x08\xc3': ('ret',)}}**

**tag: str = 'CFGFast'**

**addr_type: Literal['int', 'block_id', 'soot'] = 'int'**

**__init__**(*binary=None*, *objects=None*, *regions=None*, *pickle_intermediate_results=False*, *symbols=True*, *function_prologues=None*, *resolve_indirect_jumps=True*, *force_segment=False*, *force_smart_scan=None*, *force_complete_scan=False*, *indirect_jump_target_limit=100000*, *data_references=True*, *cross_references=False*, *normalize=False*, *start_at_entry=True*, *function_starts=None*, *extra_memory_regions=None*, *data_type_guessing_handlers=None*, *arch_options=None*, *indirect_jump_resolvers=None*, *base_state=None*, *exclude_sparse_regions=True*, *skip_specific_regions=True*, *heuristic_plt_resolving=None*, *detect_tail_calls=False*, *low_priority=False*, *cfb=None*, *model=None*, *resume_state=None*, *eh_frame=True*, *eh_frame_boundaries=True*, *exceptions=True*, *skip_unmapped_addrs=True*, *nodecode_window_size=2048*, *nodecode_threshold=0.6*, *nodecode_step=16483*, *repeating_byte_run_threshold=64*, *check_funcret_max_job=500*, *indirect_calls_always_return=None*, *jumptable_resolver_resolves_calls=None*, *retedges=False*, *drop_bad_funcs=True*, *treat_functions_as_complete=True*, *start=None*, *end=None*, *collect_data_references=None*, *extra_cross_references=None*, *elf_eh_frame=None*, ***extra_arch_options*)

**Parameters**

- **binary** – The binary to recover CFG on. By default the main binary is used.
- **objects** – A list of objects to recover the CFG on. By default it will recover the CFG of all loaded objects.
- **regions** (*iterable*) – A list of tuples in the form of (start address, end address) describing memory regions that the CFG should cover.
- **pickle_intermediate_results** (*bool*) – If we want to store the intermediate results or not.
- **symbols** (*bool*) – Get function beginnings from symbols in the binary.
- **function_prologues** (bool | None) – Scan the binary for function prologues, and use those positions as function beginnings
- **resolve_indirect_jumps** (*bool*) – Try to resolve indirect jumps. This is necessary to resolve jump targets from jump tables, etc.
- **force_segment** (*bool*) – Force CFGFast to rely on binary segments instead of sections.
- **force_complete_scan** (*bool*) – Perform a complete scan on the binary and maximize the number of identified code blocks.
- **data_references** (*bool*) – Enables the collection of references to data used by individual instructions. This does not collect 'cross-references', particularly those that involve multiple instructions. For that, see *cross_references*
- **cross_references** (*bool*) – Whether CFGFast should collect "cross-references" from the entire program or not. This will populate the knowledge base with references to and from each recognizable address constant found in the code. Note that, because this performs constant propagation on the entire program, it may be much slower and consume more memory. This option implies *data_references=True*.
- **normalize** (*bool*) – Normalize the CFG as well as all function graphs after CFG recovery.
- **start_at_entry** (*bool*) – Begin CFG recovery at the entry point of this project. Setting it to False prevents CFGFast from viewing the entry point as one of the starting points of code scanning.
- **function_starts** (*list*) – A list of extra function starting points. CFGFast will try to resume scanning from each address in the list.
- **extra_memory_regions** (*list*) – A list of 2-tuple (start-address, end-address) that shows extra memory regions. Integers falling inside will be considered as pointers.
- **indirect_jump_resolvers** (*list*) – A custom list of indirect jump resolvers. If this list is None or empty, default indirect jump resolvers specific to this architecture and binary types will be loaded.
- **base_state** – A state to use as a backer for all memory loads
- **detect_tail_calls** (*bool*) – Enable aggressive tail-call optimization detection.
- **eh_frame** (*bool*) – Retrieve function starts (and maybe sizes later) from the .eh_frame of ELF binaries or exception records of PE binaries.
- **eh_frame_boundaries** (*bool*) – Treat function starts recorded in the .eh_frame of ELF binaries as hard function boundaries while tracing, the same way symbol addresses are treated. Without it, a tail-called function that is reached through a jump before it is reached through a call is absorbed into the caller. Only used if eh_frame is enabled.

- **skip_unmapped_addrs** – Ignore all branches into unmapped regions. True by default. You may want to set it to False if you are analyzing manually patched binaries or malware samples.
- **indirect_calls_always_return** (bool | None) – Should CFG assume indirect calls must return or not. Assuming indirect calls must return will significantly reduce the number of constant propagation runs, but may reduce the overall CFG recovery precision when facing non-returning indirect calls. By default, we only assume indirect calls always return for large binaries (region > 50KB).
- **jumptable_resolver_resolves_calls** (bool | None) – Whether JumpTableResolver should resolve indirect calls or not. Most indirect calls in C++ binaries or UEFI binaries cannot be resolved using jump table resolver and must be resolved using their specific resolvers. By default, we will only disable JumpTableResolver from resolving indirect calls for large binaries (region > 50 KB).
- **repeating_byte_run_threshold** – The minimum length of a run of one repeated byte that CFGFast refuses to decode as code. Such runs are filler, but many of them decode cleanly (e.g., 0x91 is *xchg ecx, eax* on x86), so linear disassembly would otherwise walk through them forever. Runs of the architecture's nop byte are exempt because execution really does flow through them. Set it to 0 to disable the check.
- **check_funcret_max_job** – When popping return-site jobs out of the job queue, angr will prioritize jobs for which the callee is known to return. This check may be slow when there are a large amount of jobs in different caller functions, and this situation often occurs in obfuscated binaries where many functions never return. This parameter acts as a threshold to disable this check when the number of jobs in the queue exceeds this threshold.
- **start** (*int*) – (Deprecated) The beginning address of CFG recovery.
- **end** (*int*) – (Deprecated) The end address of CFG recovery.
- **arch_options** (CFGArchOptions) – Architecture-specific options.
- **extra_arch_options** – Any key-value pair in kwargs will be seen as an arch-specific option and will be used to set the option value in self._arch_options.
- **retedges** (bool) – Whether to add return edges (from function endpoints to their return sites) in the CFG. Return edges are not added by default because they are often not useful during analysis; You can set retedges to True or call make_return_edges() after CFG recovery to create return edges. Note that this option does not impact function graphs.
- **model** – An existing CFGModel to write into. When a partial model from a previously aborted CFG recovery is passed in, recovery resumes on top of it: bytes covered by existing nodes and memory data are treated as already scanned and will not be re-lifted.
- **treat_functions_as_complete** (bool) – Whether post-analysis may treat the recovered functions as complete (drop bad functions, conclude returning=False for functions without return paths). Set to False for incremental runs that extend a partial model without completing it (see the resume recipes below).
- **resume_state** (*CFGResumeState* | None) – The resume_state captured by a previously aborted CFGFast instance. Its unprocessed jobs and unresolved indirect jumps are recreated (with their original function context) so that the recovery continues where it left off. Pass it together with model=.
- **progress_callback** – (Inherited from angr.Analysis.) Callback for CFG recovery progress. The callback receives (percentage, text=..., cfg=...) where cfg is this CFGFast instance; calling cfg.abort() from the callback gracefully aborts the analysis: the core

recovery loop stops at the next job boundary, post-analysis still runs and finalizes the partially recovered model, and cfg.should_abort remains True so callers can tell the model is partial.

- **show_progressbar** (*bool*) – (Inherited from angr.Analysis.) Show a progressbar during CFG recovery.
- **force_smart_scan** (*bool | None*)
- **drop_bad_funcs** (*bool*)

Aborting and resuming CFG recovery:

After a graceful abort (see progress_callback above), self.resume_state captures the jobs that were still unprocessed (with their function context) and the unresolved indirect jumps; self.unprocessed_job_addrs holds the corresponding addresses for informational purposes. To resume recovery, create a new CFGFast instance reusing the partial model. To resume global scanning and finish the entire binary, re-inject the captured state while keeping the seeding options (symbols, function_prologues, eh_frame, force_smart_scan) at their original values:

```
proj.analyses.CFGFast(model=partial_cfg.model, start_at_entry=False,
                      resume_state=partial_cfg.resume_state)
```

Do not pass unprocessed_job_addrs as function_starts instead: function_starts seeds are treated as function heads, which would promote unprocessed call return sites and intra-function jump targets to functions.

To only resume from specific addresses (they must not be part of the partial model already; seeding an already-scanned address is a no-op):

```
proj.analyses.CFGFast(model=partial_cfg.model, function_starts=[addr], start_at_
↪entry=False,
                      symbols=False, function_prologues=False, eh_frame=False,
                      force_smart_scan=False, force_complete_scan=False,
                      treat_functions_as_complete=False)
```

treat_functions_as_complete=False tells post-analysis that the resulting model is still partial: functions must not be dropped as bad, and returning=False must not be concluded for (possibly truncated) functions - such conclusions would poison a later full resume the same way an abort would without them being reset.

**Returns**
None

**Parameters**

- **function_prologues** (*bool | None*)
- **force_smart_scan** (*bool | None*)
- **resume_state** (*CFGResumeState | None*)
- **indirect_calls_always_return** (*bool | None*)
- **jumptable_resolver_resolves_calls** (*bool | None*)
- **retedges** (*bool*)
- **drop_bad_funcs** (*bool*)
- **treat_functions_as_complete** (*bool*)

**unprocessed_job_addrs:** `set[int]`

resume_state: *CFGResumeState* | None

stage: str

property graph: *SpillingCFG*

property memory_data

property jump_tables

property insn_addr_to_memory_data

do_full_xrefs(*overlay_state=None*)

Perform xref recovery on all functions.

**Parameters**
**overlay** (SimState) – An overlay state for loading constant data.

**Returns**
None

drop_bad_functions()

make_return_edges()

For each returning function, create return edges in self.graph.

**Returns**
None

copy()

output()

class angr.analyses.cfg.CFGFastSoot

Bases: *CFGFast*

addr_type: Literal['int', 'block_id', 'soot'] = 'soot'

drop_bad_functions()

make_functions()

Revisit the entire control flow graph, create Function instances accordingly, and correctly put blocks into each function.

Although Function objects are crated during the CFG recovery, they are neither sound nor accurate. With a pre-constructed CFG, this method rebuilds all functions bearing the following rules:

- A block may only belong to one function.
- Small functions lying inside the startpoint and the endpoint of another function will be merged with the other function
- Tail call optimizations are detected.
- PLT stubs are aligned by 16.

**Returns**
None

### angr.analyses.cfg.cfb

**class** angr.analyses.cfg.cfb.**CFBlanketView**

Bases: object

A view into the control-flow blanket.

**__init__**(*cfb*)

**class** angr.analyses.cfg.cfb.**MemoryRegion**

Bases: object

**__init__**(*addr*, *size*, *type_*, *object_*, *cle_region*)

**class** angr.analyses.cfg.cfb.**Unknown**

Bases: object

An unknown byte region in a control-flow blanket.

**MAX_BYTES = 1616**

**__init__**(*addr*, *size*, *bytes_=None*, *object_=None*, *segment=None*, *section=None*, *loader=None*)

**property bytes**

The bytes of this region, for display purposes. Lazily loaded on first access (and capped at MAX_BYTES) when a loader is available.

**trimmed**(*new_start*, *new_size*)

Create a copy of this region covering [new_start, new_start + new_size). Bytes that were already loaded are sliced instead of being loaded again.

**Return type**
*Unknown*

**Parameters**

- **new_start** (*int*)
- **new_size** (*int*)

class angr.analyses.cfg.cfb.**CFBlanket**

Bases: *Analysis*

A Control-Flow Blanket is a representation for storing all instructions, data entries, and bytes of a full program.

Region types: - section - segment - extern - tls - kernel

**__init__**(*exclude_region_types=None*, *on_object_added=None*, *on_object_removed=None*)

**Parameters**

- **on_object_added** (Callable[[int, Any], None] | None) – Callable with parameters (addr, obj) called after an object is added to the blanket.
- **on_object_removed** (Callable[[int, Any], None] | None) – Callable with parameters (addr, obj) called after an object is removed from the blanket.
- **exclude_region_types** (*set[str] | None*)

**property regions**

Return all memory regions.

**floor_addr**(*addr*)

**Return type**
int

**Parameters**
**addr** (*int*)

**floor_item**(*addr*)

**Return type**
tuple[int, Any]

**Parameters**
**addr** (*int*)

**floor_items**(*addr=None*, *reverse=False*)

**ceiling_addr**(*addr*)

**Return type**
int

**Parameters**
**addr** (*int*)

**ceiling_item**(*addr*)

**Return type**
tuple[int, Any]

**Parameters**
**addr** (*int*)

**ceiling_items**(*addr=None*, *reverse=False*, *include_first=True*)

**add_obj**(*addr*, *obj*)

Add an object *obj* to the blanket at the specified address *addr*, keeping the blanket non-overlapping: existing objects that overlap [addr, addr + obj.size) are removed or trimmed, and the trimmed-off remainders are re-inserted. Objects without an integer size are stored as zero-span entries and never cause trimming.

**remove_obj**(*addr*, *fill=True*)

Remove the object at *addr* from the blanket. When *fill* is set (the default), the removed object's span is re-filled with an Unknown region so that the blanket remains a total cover of the mapped address space. Removing a missing address is a no-op.

**Returns**
The removed object, or None if no object exists at *addr*.

**Parameters**
**fill** (*bool*)

**add_function**(*func*)

Add a function *func* and all blocks of this function to the blanket.

**dbg_repr**()

The debugging representation of this CFBlanket.

**Returns**
The debugging representation of this CFBlanket.

**Return type**
str

### angr.analyses.cfg.cfg

**exception** angr.analyses.cfg.cfg.**OutdatedError**

Bases: Exception

**class** angr.analyses.cfg.cfg.**CFG**

Bases: *CFGFast*

tl;dr: CFG is just a wrapper around CFGFast for compatibility issues. It will be fully replaced by CFGFast in future releases. Feel free to use CFG if you intend to use CFGFast. Please use CFGEmulated if you *have to* use the old, slow, dynamically-generated version of CFG.

For multiple historical reasons, angr's CFG is accurate but slow, which does not meet what most people expect. We developed CFGFast for light-speed CFG recovery, and renamed the old CFG class to CFGEmulated. For compatibility concerns, CFG was kept as an alias to CFGEmulated.

However, so many new users of angr would load up a binary and generate a CFG immediately after running "pip install angr", and draw the conclusion that "angr's CFG is so slow - angr must be unusable!" Therefore, we made the hard decision: CFG will be an alias to CFGFast, instead of CFGEmulated.

To ease the transition of your existing code and script, the following changes are made:

- A CFG class, which is a sub class of CFGFast, is created.
- You will see both a warning message printed out to stderr and an exception raised by angr if you are passing CFG any parameter that only CFGEmulated supports. This exception is not a sub class of AngrError, so you wouldn't capture it with your old code by mistake.
- In the near future, this wrapper class will be removed completely, and CFG will be a simple alias to CFGFast.

We expect most interfaces are the same between CFGFast and CFGEmulated. Apparently some functionalities (like context-sensitivity, and state keeping) only exist in CFGEmulated, which is when you want to use CFGEmulated instead.

### angr.analyses.cfg.cfg_arch_options

**class** angr.analyses.cfg.cfg_arch_options.**CFGArchOptions**

Bases: object

Stores architecture-specific options and settings, as well as the detailed explanation of those options and settings.

Suppose *ao* is the CFGArchOptions object, and there is an option called *ret_jumpkind_heuristics*, you can access it by *ao.ret_jumpkind_heuristics* and set its value via *ao.ret_jumpkind_heuristics = True*

**Variables**

- **OPTIONS** (*dict*) – A dict of all default options for different architectures.
- **arch** (*archinfo.Arch*) – The architecture object.
- **_options** (*dict*) – Values of all CFG options that are specific to the current architecture.

**OPTIONS = {'ARMCortexM': {'has_arm_code': (<class 'bool'>, False), 'pattern_match_ifuncs': (<class 'bool'>, True), 'ret_jumpkind_heuristics': (<class 'bool'>, True), 'switch_mode_on_nodecode': (<class 'bool'>, False)}, 'ARMEL': {'has_arm_code': (<class 'bool'>, True), 'pattern_match_ifuncs': (<class 'bool'>, True), 'ret_jumpkind_heuristics': (<class 'bool'>, True), 'switch_mode_on_nodecode': (<class 'bool'>, True)}, 'ARMHF': {'has_arm_code': (<class 'bool'>, True), 'pattern_match_ifuncs': (<class 'bool'>, True), 'ret_jumpkind_heuristics': (<class 'bool'>, True), 'switch_mode_on_nodecode': (<class 'bool'>, True)}}**

**__init__**(*arch*, ***options*)

Constructor.

**Parameters**

- **arch** (*archinfo.Arch*) – The architecture instance.
- **options** (*dict*) – Architecture-specific options, which will be used to initialize this object.

**arch = None**

### angr.analyses.cfg.cfg_base

**class** angr.analyses.cfg.cfg_base.**CFGBase**

Bases: *Analysis*

The base class for control flow graphs.

**tag: str = None**

**addr_type: Literal['int', 'block_id', 'soot'] = None**

**__init__**(*sort*, *context_sensitivity_level*, *normalize=False*, *binary=None*, *objects=None*, *regions=None*, *exclude_sparse_regions=True*, *skip_specific_regions=True*, *force_segment=False*, *base_state=None*, *resolve_indirect_jumps=True*, *indirect_jump_resolvers=None*, *indirect_jump_target_limit=100000*, *detect_tail_calls=False*, *low_priority=False*, *skip_unmapped_addrs=True*, *sp_tracking_track_memory=True*, *model=None*)

**Parameters**

- **sort** (*str*) – 'fast' or 'emulated'.
- **context_sensitivity_level** (*int*) – The level of context-sensitivity of this CFG (see documentation for further details). It ranges from 0 to infinity.

- **normalize** (*bool*) – Whether the CFG as well as all Function graphs should be normalized.
- **binary** (*cle.backends.Backend*) – The binary to recover CFG on. By default, the main binary is used.
- **objects** – A list of objects to recover the CFG on. By default, it will recover the CFG of all loaded objects.
- **regions** (*iterable*) – A list of tuples in the form of (start address, end address) describing memory regions that the CFG should cover.
- **force_segment** (*bool*) – Force CFGFast to rely on binary segments instead of sections.
- **base_state** (*angr.SimState*) – A state to use as a backer for all memory loads.
- **resolve_indirect_jumps** (*bool*) – Whether to try to resolve indirect jumps. This is necessary to resolve jump targets from jump tables, etc.
- **indirect_jump_resolvers** (*list*) – A custom list of indirect jump resolvers. If this list is None or empty, default indirect jump resolvers specific to this architecture and binary types will be loaded.
- **indirect_jump_target_limit** (*int*) – Maximum indirect jump targets to be recovered.
- **skip_unmapped_addrs** – Ignore all branches into unmapped regions. True by default. You may want to set it to False if you are analyzing manually patched binaries or malware samples.
- **detect_tail_calls** (*bool*) – Aggressive tail-call optimization detection. This option is only respected in make_functions().
- **sp_tracking_track_memory** (*bool*) – Whether or not to track memory writes if tracking the stack pointer. This increases the accuracy of stack pointer tracking, especially for architectures without a base pointer. Only used if detect_tail_calls is enabled.
- **model** (*None or CFGModel*) – The CFGModel instance to write to. A new CFGModel instance will be created and registered with the knowledge base if *model* is None.

**Returns**
None

**indirect_jumps:** `dict[int, IndirectJump]`

**property model:** *CFGModel*

Get the CFGModel instance. :return: The CFGModel instance that this analysis currently uses.

**property normalized**

**property context_sensitivity_level**

**property functions**

A reference to the FunctionManager in the current knowledge base.

**Returns**
FunctionManager with all functions

**Return type**
angr.knowledge_plugins.FunctionManager

**property regions:** `list[tuple[int, int]]`

The memory regions that this analysis covers. An empty list means it had nothing to scan.

**Returns**
A sorted list of (start address, end address) tuples.

`make_copy`(*copy_to*)

Copy self attributes to the new object.

**Parameters**
**copy_to** (CFGBase) – The target to copy to.

**Returns**
None

`copy`()

`output`()

`generate_index`()

Generate an index of all nodes in the graph in order to speed up get_any_node() with anyaddr=True.

**Returns**
None

`get_loop_back_edges`()

`property graph: SpillingCFG`

`remove_edge`(*block_from*, *block_to*)

`is_thumb_addr`(*addr*)

`record_memory_data_addr`(*addr*)

Record the address of a newly added memory data object.

**Return type**
None

**Parameters**
**addr** (*int*)

`reset_memory_data_addrs`()

Reset the set of addresses of newly added memory data objects.

**Return type**
None

`normalize`()

Normalize the CFG, making sure that there are no overlapping basic blocks.

Note that this method will not alter transition graphs of each function in self.kb.functions. You may call normalize() on each Function object to normalize their transition graphs.

**Returns**
None

`mark_function_alignments`()

Find all potential function alignments and mark them.

Note that it is not always correct to simply remove them, because these functions may not be actual alignments but part of an actual function, and is incorrectly marked as an individual function because of failures in resolving indirect jumps. An example is in the test binary `x86_64/dir_gcc_-O0` 0x40541d (indirect jump at 0x4051b0). If the indirect jump cannot be correctly resolved, removing function 0x40541d will cause a missing label failure in reassembler.

**Returns**
None

`make_functions()`

Revisit the entire control flow graph, create Function instances accordingly, and correctly put blocks into each function.

Although Function objects are created during the CFG recovery, they are neither sound nor accurate. With a pre-constructed CFG, this method rebuilds all functions bearing the following rules:

- A block may only belong to one function.
- Small functions lying inside the startpoint and the endpoint of another function will be merged with the other function
- Tail call optimizations are detected.
- PLT stubs are aligned by 16.

**Returns**
None

### angr.analyses.cfg.cfg_emulated

`class angr.analyses.cfg.cfg_emulated.CFGJob`

Bases: *CFGJobBase*

The job class that CFGEmulated uses.

`__init__(*args, **kwargs)`

`property block_id`

`property is_syscall`

`class angr.analyses.cfg.cfg_emulated.PendingJob`

Bases: `object`

A PendingJob is whatever will be put into our pending_exit list. A pending exit is an entry that created by the returning of a call or syscall. It is "pending" since we cannot immediately figure out whether this entry will be executed or not. If the corresponding call/syscall intentionally doesn't return, then the pending exit will be removed. If the corresponding call/syscall returns, then the pending exit will be removed as well (since a real entry is created from the returning and will be analyzed later). If the corresponding call/syscall might return, but for some reason (for example, an unsupported instruction is met during the analysis) our analysis does not return properly, then the pending exit will be picked up and put into remaining_jobs list.

`__init__(caller_func_addr, returning_source, state, src_block_id, src_exit_stmt_idx, src_exit_ins_addr, call_stack)`

**Parameters**

- **returning_source** – Address of the callee function. It might be None if address of the callee is not resolvable.
- **state** – The state after returning from the callee function. Of course there is no way to get a precise state without emulating the execution of the callee, but at least we can properly adjust the stack and registers to imitate the real returned state.
- **call_stack** – A callstack.

class angr.analyses.cfg.cfg_emulated.**CFGEmulated**

Bases: *ForwardAnalysis*, *CFGBase*

This class represents a control-flow graph.

**tag:** `str = 'CFGEmulated'`

**addr_type:** `Literal['int', 'block_id', 'soot'] = 'block_id'`

**__init__**(*context_sensitivity_level=1*, *start=None*, *avoid_runs=None*, *enable_function_hints=False*, *call_depth=None*, *call_tracing_filter=None*, *initial_state=None*, *starts=None*, *keep_state=False*, *indirect_jump_target_limit=100000*, *resolve_indirect_jumps=True*, *enable_advanced_backward_slicing=False*, *enable_symbolic_back_traversal=False*, *indirect_jump_resolvers=None*, *additional_edges=None*, *no_construct=False*, *normalize=False*, *max_iterations=1*, *address_whitelist=None*, *base_graph=None*, *iropt_level=None*, *max_steps=None*, *state_add_options=None*, *state_remove_options=None*, *model=None*)

All parameters are optional.

**Parameters**

- **context_sensitivity_level** – The level of context-sensitivity of this CFG (see documentation for further details). It ranges from 0 to infinity. Default 1.
- **avoid_runs** – A list of runs to avoid.
- **enable_function_hints** – Whether to use function hints (constants that might be used as exit targets) or not.
- **call_depth** – How deep in the call stack to trace.
- **call_tracing_filter** – Filter to apply on a given path and jumpkind to determine if it should be skipped when call_depth is reached.
- **initial_state** – An initial state to use to begin analysis.
- **starts** (*iterable*) – A collection of starting points to begin analysis. It can contain the following three different types of entries: an address specified as an integer, a 2-tuple that includes an integer address and a jumpkind, or a SimState instance. Unsupported entries in starts will lead to an AngrCFGError being raised.
- **keep_state** – Whether to keep the SimStates for each CFGNode.
- **resolve_indirect_jumps** – Whether to enable the indirect jump resolvers for resolving indirect jumps
- **enable_advanced_backward_slicing** – Whether to enable an intensive technique for resolving indirect jumps
- **enable_symbolic_back_traversal** – Whether to enable an intensive technique for resolving indirect jumps
- **indirect_jump_resolvers** (*list*) – A custom list of indirect jump resolvers. If this list is None or empty, default indirect jump resolvers specific to this architecture and binary types will be loaded.
- **additional_edges** – A dict mapping addresses of basic blocks to addresses of successors to manually include and analyze forward from.
- **no_construct** (*bool*) – Skip the construction procedure. Only used in unit-testing.
- **normalize** (*bool*) – If the CFG as well as all Function graphs should be normalized or not.

- **max_iterations** (*int*) – The maximum number of iterations that each basic block should be "executed". 1 by default. Larger numbers of iterations are usually required for complex analyses like loop analysis.
- **address_whitelist** (*iterable*) – A list of allowed addresses. Any basic blocks outside of this collection of addresses will be ignored.
- **base_graph** (*networkx.DiGraph*) – A basic control flow graph to follow. Each node inside this graph must have the following properties: *addr* and *size*. CFG recovery will strictly follow nodes and edges shown in the graph, and discard any control flow that does not follow an existing edge in the base graph. For example, you can pass in a Function local transition graph as the base graph, and CFGEmulated will traverse nodes and edges and extract useful information.
- **iropt_level** (*int*) – The optimization level of VEX IR (0, 1, 2). The default level will be used if *iropt_level* is None.
- **max_steps** (*int*) – The maximum number of basic blocks to recover forthe longest path from each start before pausing the recovery procedure.
- **state_add_options** – State options that will be added to the initial state.
- **state_remove_options** – State options that will be removed from the initial state.

**copy**()

Make a copy of the CFG.

**Return type**
*CFGEmulated*

**Returns**
A copy of the CFG instance.

**resume**(*starts=None*, *max_steps=None*)

Resume a paused or terminated control flow graph recovery.

**Parameters**

- **starts** (*iterable*) – A collection of new starts to resume from. If *starts* is None, we will resume CFG recovery from where it was paused before.
- **max_steps** (*int*) – The maximum number of blocks on the longest path starting from each start before pausing the recovery.

**Returns**
None

**remove_cycles**()

Forces graph to become acyclic, removes all loop back edges and edges between overlapped loop headers and their successors.

**downsize**()

Remove saved states from all CFGNodes to reduce memory usage.

**Returns**
None

**unroll_loops**(*max_loop_unrolling_times*)

Unroll loops for each function. The resulting CFG may still contain loops due to recursion, function calls, etc.

**Parameters**
**max_loop_unrolling_times** (*int*) – The maximum iterations of unrolling.

**Returns**
None

**force_unroll_loops**(*max_loop_unrolling_times*)

Unroll loops globally. The resulting CFG does not contain any loop, but this method is slow on large graphs.

**Parameters**
**max_loop_unrolling_times** (*int*) – The maximum iterations of unrolling.

**Returns**
None

**immediate_dominators**(*start*, *target_graph=None*)

Get all immediate dominators of sub graph from given node upwards.

**Parameters**

- **start** (*str*) – id of the node to navigate forwards from.
- **target_graph** (*networkx.classes.digraph.DiGraph*) – graph to analyse, default is self.graph.

**Returns**
each node of graph as index values, with element as respective node's immediate dominator.

**Return type**
dict

**immediate_postdominators**(*end*, *target_graph=None*)

Get all immediate postdominators of sub graph from given node upwards.

**Parameters**

- **start** (*str*) – id of the node to navigate forwards from.
- **target_graph** (*networkx.classes.digraph.DiGraph*) – graph to analyse, default is self.graph.

**Returns**
each node of graph as index values, with element as respective node's immediate dominator.

**Return type**
dict

**remove_fakerets**()

Get rid of fake returns (i.e., Ijk_FakeRet edges) from this CFG

**Returns**
None

**get_topological_order**(*cfg_node*)

Get the topological order of a CFG Node.

**Parameters**
**cfg_node** – A CFGNode instance.

**Returns**
An integer representing its order, or None if the CFGNode does not exist in the graph.

**get_subgraph**(*starting_node*, *block_addresses*)

Get a sub-graph out of a bunch of basic block addresses.

**Parameters**

- **starting_node** (CFGNode) – The beginning of the subgraph
- **block_addresses** (*iterable*) – A collection of block addresses that should be included in the subgraph if there is a path between *starting_node* and a CFGNode with the specified address, and all nodes on the path should also be included in the subgraph.

**Returns**
A new CFG that only contain the specific subgraph.

**Return type**
*CFGEmulated*

**get_function_subgraph**(*start*, *max_call_depth=None*)

Get a sub-graph of a certain function.

**Parameters**

- **start** – The function start. Currently it should be an integer.
- **max_call_depth** – Call depth limit. None indicates no limit.

**Returns**
A CFG instance which is a sub-graph of self.graph

**property context_sensitivity_level**

**property graph:** *SpillingCFG*

**property unresolvables**

Get those SimRuns that have non-resolvable exits.

**Returns**
A set of SimRuns

**Return type**
set

**property deadends**

Get all CFGNodes that has an out-degree of 0

**Returns**
A list of CFGNode instances

**Return type**
list

### angr.analyses.cfg.cfg_fast

**exception** angr.analyses.cfg.cfg_fast.**ContinueScanningNotification**

Bases: RuntimeError

A notification raised by _next_code_addr_core() to indicate no code address is found and _next_code_addr_core() should be invoked again.

**class** angr.analyses.cfg.cfg_fast.**ARMDecodingMode**

Bases: object

Enums indicating decoding mode for ARM code.

**ARM = 0**

**THUMB = 1**

**class** angr.analyses.cfg.cfg_fast.**DecodingAssumption**

Bases: object

Describes the decoding mode (ARM/THUMB) for a given basic block identified by its address.

**__init__**(*addr*, *size*, *mode*)

**Parameters**

- **addr** (*int*)
- **size** (*int*)
- **mode** (*int*)

**add_data_seg**(*addr*, *size*)

**Return type**
None

**Parameters**

- **addr** (*int*)
- **size** (*int*)

**class** angr.analyses.cfg.cfg_fast.**FunctionReturn**

Bases: object

FunctionReturn describes a function call in a specific location and its return location. Hashable and equatable

**__init__**(*callee_func_addr*, *caller_func_addr*, *call_site_addr*, *return_to*)

**callee_func_addr**

**caller_func_addr**

**call_site_addr**

**return_to**

**class** angr.analyses.cfg.cfg_fast.**PendingJobs**

Bases: object

A collection of pending jobs during CFG recovery.

**__init__**(*kb*, *deregister_job_callback*)

**add_job**(*job*)

**all_jobs**()

Iterate over all pending jobs.

**Returns**
An iterator over all pending CFGJob instances.

**pop_job**(*returning=True*)

Pop a job from the pending jobs list.

When returning == True, we prioritize the jobs whose functions are known to be returning (function.returning is True). As an optimization, we are sorting the pending jobs list according to job.function.returning.

**Parameters**
**returning** (*bool*) – Only pop a pending job if the corresponding function returns.

**Returns**
A pending job if we can find one, or None if we cannot find any that satisfies the requirement.

**Return type**
*angr.analyses.cfg.cfg_fast.CFGJob*

**cleanup**()

Remove those pending exits if: a) they are the return exits of non-returning SimProcedures b) they are the return exits of non-returning syscalls b) they are the return exits of non-returning functions

**Returns**
None

**add_returning_function**(*func_addr*)

Mark a function as returning.

**Parameters**
**func_addr** (*int*) – Address of the function that returns.

**Returns**
None

**add_nonreturning_function**(*func_addr*)

Mark a function as not returning.

**Parameters**
**func_addr** (*int*) – Address of the function that does not return.

**Returns**
None

**clear_updated_functions**()

Clear the updated_functions set.

**Returns**
None

**class** angr.analyses.cfg.cfg_fast.**ResumeJob**

Bases: NamedTuple

Describes an unprocessed CFGJob captured when a CFG recovery is aborted, with enough context to faithfully re-create the job when the recovery is resumed: func_addr preserves the function that the job belongs to (so that resuming does not promote mid-function block addresses, e.g. call return sites, to function heads), and the source block and function edges are stored as addresses (so that no CFGNode references survive across analyses) and are re-resolved against the model when the job is re-created.

**addr:** int

Alias for field number 0

**func_addr:** int

Alias for field number 1

**jumpkind:** str

Alias for field number 2

**returning_source:** int | None

Alias for field number 3

**syscall:** bool

Alias for field number 4

**gp:** int | None

Alias for field number 5

**static __new__**(*_cls*, *addr*, *func_addr*, *jumpkind*, *returning_source=None*, *syscall=False*, *gp=None*, *last_addr=None*, *src_node_addr=None*, *src_ins_addr=None*, *src_stmt_idx=None*, *func_edges=()*)

Create new instance of ResumeJob(addr, func_addr, jumpkind, returning_source, syscall, gp, last_addr, src_node_addr, src_ins_addr, src_stmt_idx, func_edges)

**Parameters**

- **addr** (*int*)
- **func_addr** (*int*)
- **jumpkind** (*str*)
- **returning_source** (*int | None*)
- **syscall** (*bool*)
- **gp** (*int | None*)
- **last_addr** (*int | None*)
- **src_node_addr** (*int | None*)
- **src_ins_addr** (*int | None*)
- **src_stmt_idx** (*int | None*)
- **func_edges** (*tuple[tuple, ...]*)

**class** angr.analyses.cfg.cfg_fast.**CFGResumeState**

Bases: object

Captured state of an aborted CFG recovery. Pass it to a new CFGFast instance (via the resume_state parameter, together with model=) to resume the recovery where it left off.

__init__(*jobs=None*, *indirect_jumps=None*)

**Parameters**

- **jobs** (*list[ResumeJob] | None*)
- **indirect_jumps** (*list[IndirectJump] | None*)

**jobs:** list[*ResumeJob*]

**indirect_jumps:** list[*IndirectJump*]

class angr.analyses.cfg.cfg_fast.**FunctionEdge**

Bases: object

Describes an edge in functions' transition graphs. Base class for all types of edges.

**apply**(*cfg*)

**ins_addr**

**src_func_addr**

**stmt_idx**

class angr.analyses.cfg.cfg_fast.**FunctionTransitionEdge**

Bases: *FunctionEdge*

Describes a transition edge in functions' transition graphs.

__init__(*src_node*, *dst_addr*, *src_func_addr*, *to_outside=False*, *dst_func_addr=None*, *stmt_idx=None*, *ins_addr=None*, *is_exception=False*)

**src_node**

**dst_addr**

**to_outside**

**dst_func_addr**

**is_exception**

**apply**(*cfg*)

class angr.analyses.cfg.cfg_fast.**FunctionCallEdge**

Bases: *FunctionEdge*

Describes a call edge in functions' transition graphs.

__init__(*src_node*, *dst_addr*, *ret_addr*, *src_func_addr*, *syscall=False*, *stmt_idx=None*, *ins_addr=None*)

**src_node**

**dst_addr**

**ret_addr**

**syscall**

**apply**(*cfg*)

class angr.analyses.cfg.cfg_fast.**FunctionFakeRetEdge**

Bases: *FunctionEdge*

Describes a FakeReturn (also called fall-through) edge in functions' transition graphs.

**__init__**(*src_node*, *dst_addr*, *src_func_addr*, *confirmed=None*)

**src_node**

**dst_addr**

**confirmed**

**apply**(*cfg*)

class angr.analyses.cfg.cfg_fast.**FunctionReturnEdge**

Bases: *FunctionEdge*

Describes a return (from a function call or a syscall) edge in functions' transition graphs.

**__init__**(*ret_from_addr*, *ret_to_addr*, *dst_func_addr*)

**ret_from_addr**

**ret_to_addr**

**dst_func_addr**

**apply**(*cfg*)

class angr.analyses.cfg.cfg_fast.**CFGJobType**

Bases: Enum

Defines the type of work of a CFGJob

**NORMAL = 0**

**FUNCTION_PROLOGUE = 1**

**COMPLETE_SCANNING = 2**

**IFUNC_HINTS = 3**

**DATAREF_HINTS = 4**

**EH_FRAME_HINTS = 5**

class angr.analyses.cfg.cfg_fast.**CFGJob**

Bases: object

Defines a job to work on during the CFG recovery

**__init__**(*addr*, *func_addr*, *jumpkind*, *ret_target=None*, *last_addr=None*, *src_node=None*, *src_ins_addr=None*, *src_stmt_idx=None*, *returning_source=None*, *syscall=False*, *func_edges=None*, *job_type=CFGJobType.NORMAL*, *gp=None*)

**Parameters**

- **addr** (*int*)
- **func_addr** (*int*)
- **jumpkind** (*str*)

- **ret_target** (*int | None*)
- **last_addr** (*int | None*)
- **src_node** (CFGNode | *None*)
- **src_ins_addr** (*int | None*)

**add_function_edge**(*edge*)

**apply_function_edges**(*cfg*, *clear=False*)

**class** angr.analyses.cfg.cfg_fast.**CFGFast**

Bases: *ForwardAnalysis*[*CFGNode*, *CFGNode*, *CFGJob*, int, object], *CFGBase*

We find functions inside the given binary, and build a control-flow graph in very fast manners: instead of simulating program executions, keeping track of states, and performing expensive data-flow analysis, CFGFast will only perform light-weight analyses combined with some heuristics, and with some strong assumptions.

In order to identify as many functions as possible, and as accurate as possible, the following operation sequence is followed:

# Active scanning

- If the binary has "function symbols" (TODO: this term is not accurate enough), they are starting points of the code scanning
- If the binary does not have any "function symbol", we will first perform a function prologue scanning on the entire binary, and start from those places that look like function beginnings
- Otherwise, the binary's entry point will be the starting point for scanning

# Passive scanning

- After all active scans are done, we will go through the whole image and scan all code pieces

Due to the nature of those techniques that are used here, a base address is often not required to use this analysis routine. However, with a correct base address, CFG recovery will almost always yield a much better result. A custom analysis, called GirlScout, is specifically made to recover the base address of a binary blob. After the base address is determined, you may want to reload the binary with the new base address by creating a new Project object, and then re-recover the CFG.

**PROLOGUE_SCAN_PADDING = 64**

**PRINTABLES = b'0123456789abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ!"#$%&\
'()*+,-./:;<=>?@[\\]^_`{|}~ \t\n\r'**

**SPECIAL_THUNKS = {'AMD64':

b'\xe8\x07\x00\x00\x00\xf3\x90\x0f\xae\xe8\xeb\xf9H\x8dd$\x08\xc3': ('ret',)}}**

**tag: str = 'CFGFast'**

**addr_type: Literal['int', 'block_id', 'soot'] = 'int'**

**__init__**(*binary=None*, *objects=None*, *regions=None*, *pickle_intermediate_results=False*, *symbols=True*, *function_prologues=None*, *resolve_indirect_jumps=True*, *force_segment=False*, *force_smart_scan=None*, *force_complete_scan=False*, *indirect_jump_target_limit=100000*, *data_references=True*, *cross_references=False*, *normalize=False*, *start_at_entry=True*, *function_starts=None*, *extra_memory_regions=None*, *data_type_guessing_handlers=None*, *arch_options=None*, *indirect_jump_resolvers=None*, *base_state=None*, *exclude_sparse_regions=True*, *skip_specific_regions=True*, *heuristic_plt_resolving=None*, *detect_tail_calls=False*, *low_priority=False*, *cfb=None*, *model=None*, *resume_state=None*, *eh_frame=True*, *eh_frame_boundaries=True*, *exceptions=True*, *skip_unmapped_addrs=True*, *nodecode_window_size=2048*, *nodecode_threshold=0.6*, *nodecode_step=16483*, *repeating_byte_run_threshold=64*, *check_funcret_max_job=500*, *indirect_calls_always_return=None*, *jumptable_resolver_resolves_calls=None*, *retedges=False*, *drop_bad_funcs=True*, *treat_functions_as_complete=True*, *start=None*, *end=None*, *collect_data_references=None*, *extra_cross_references=None*, *elf_eh_frame=None*, ***extra_arch_options*)

**Parameters**

- **binary** – The binary to recover CFG on. By default the main binary is used.
- **objects** – A list of objects to recover the CFG on. By default it will recover the CFG of all loaded objects.
- **regions** (*iterable*) – A list of tuples in the form of (start address, end address) describing memory regions that the CFG should cover.
- **pickle_intermediate_results** (*bool*) – If we want to store the intermediate results or not.
- **symbols** (*bool*) – Get function beginnings from symbols in the binary.
- **function_prologues** (bool | None) – Scan the binary for function prologues, and use those positions as function beginnings
- **resolve_indirect_jumps** (*bool*) – Try to resolve indirect jumps. This is necessary to resolve jump targets from jump tables, etc.
- **force_segment** (*bool*) – Force CFGFast to rely on binary segments instead of sections.

- **force_complete_scan** (*bool*) – Perform a complete scan on the binary and maximize the number of identified code blocks.
- **data_references** (*bool*) – Enables the collection of references to data used by individual instructions. This does not collect 'cross-references', particularly those that involve multiple instructions. For that, see *cross_references*
- **cross_references** (*bool*) – Whether CFGFast should collect "cross-references" from the entire program or not. This will populate the knowledge base with references to and from each recognizable address constant found in the code. Note that, because this performs constant propagation on the entire program, it may be much slower and consume more memory. This option implies *data_references=True*.
- **normalize** (*bool*) – Normalize the CFG as well as all function graphs after CFG recovery.
- **start_at_entry** (*bool*) – Begin CFG recovery at the entry point of this project. Setting it to False prevents CFGFast from viewing the entry point as one of the starting points of code scanning.
- **function_starts** (*list*) – A list of extra function starting points. CFGFast will try to resume scanning from each address in the list.
- **extra_memory_regions** (*list*) – A list of 2-tuple (start-address, end-address) that shows extra memory regions. Integers falling inside will be considered as pointers.
- **indirect_jump_resolvers** (*list*) – A custom list of indirect jump resolvers. If this list is None or empty, default indirect jump resolvers specific to this architecture and binary types will be loaded.
- **base_state** – A state to use as a backer for all memory loads
- **detect_tail_calls** (*bool*) – Enable aggressive tail-call optimization detection.
- **eh_frame** (*bool*) – Retrieve function starts (and maybe sizes later) from the .eh_frame of ELF binaries or exception records of PE binaries.
- **eh_frame_boundaries** (*bool*) – Treat function starts recorded in the .eh_frame of ELF binaries as hard function boundaries while tracing, the same way symbol addresses are treated. Without it, a tail-called function that is reached through a jump before it is reached through a call is absorbed into the caller. Only used if eh_frame is enabled.
- **skip_unmapped_addrs** – Ignore all branches into unmapped regions. True by default. You may want to set it to False if you are analyzing manually patched binaries or malware samples.
- **indirect_calls_always_return** (bool | None) – Should CFG assume indirect calls must return or not. Assuming indirect calls must return will significantly reduce the number of constant propagation runs, but may reduce the overall CFG recovery precision when facing non-returning indirect calls. By default, we only assume indirect calls always return for large binaries (region > 50KB).
- **jumptable_resolver_resolves_calls** (bool | None) – Whether JumpTableResolver should resolve indirect calls or not. Most indirect calls in C++ binaries or UEFI binaries cannot be resolved using jump table resolver and must be resolved using their specific resolvers. By default, we will only disable JumpTableResolver from resolving indirect calls for large binaries (region > 50 KB).
- **repeating_byte_run_threshold** – The minimum length of a run of one repeated byte that CFGFast refuses to decode as code. Such runs are filler, but many of them decode cleanly (e.g., 0x91 is *xchg ecx, eax* on x86), so linear disassembly would otherwise walk

through them forever. Runs of the architecture's nop byte are exempt because execution really does flow through them. Set it to 0 to disable the check.

- **check_funcret_max_job** – When popping return-site jobs out of the job queue, angr will prioritize jobs for which the callee is known to return. This check may be slow when there are a large amount of jobs in different caller functions, and this situation often occurs in obfuscated binaries where many functions never return. This parameter acts as a threshold to disable this check when the number of jobs in the queue exceeds this threshold.
- **start** (*int*) – (Deprecated) The beginning address of CFG recovery.
- **end** (*int*) – (Deprecated) The end address of CFG recovery.
- **arch_options** (CFGArchOptions) – Architecture-specific options.
- **extra_arch_options** – Any key-value pair in kwargs will be seen as an arch-specific option and will be used to set the option value in self._arch_options.
- **retedges** (bool) – Whether to add return edges (from function endpoints to their return sites) in the CFG. Return edges are not added by default because they are often not useful during analysis; You can set retedges to True or call make_return_edges() after CFG recovery to create return edges. Note that this option does not impact function graphs.
- **model** – An existing CFGModel to write into. When a partial model from a previously aborted CFG recovery is passed in, recovery resumes on top of it: bytes covered by existing nodes and memory data are treated as already scanned and will not be re-lifted.
- **treat_functions_as_complete** (bool) – Whether post-analysis may treat the recovered functions as complete (drop bad functions, conclude returning=False for functions without return paths). Set to False for incremental runs that extend a partial model without completing it (see the resume recipes below).
- **resume_state** (*CFGResumeState* | None) – The resume_state captured by a previously aborted CFGFast instance. Its unprocessed jobs and unresolved indirect jumps are recreated (with their original function context) so that the recovery continues where it left off. Pass it together with model=.
- **progress_callback** – (Inherited from angr.Analysis.) Callback for CFG recovery progress. The callback receives (percentage, text=..., cfg=...) where cfg is this CFGFast instance; calling cfg.abort() from the callback gracefully aborts the analysis: the core recovery loop stops at the next job boundary, post-analysis still runs and finalizes the partially recovered model, and cfg.should_abort remains True so callers can tell the model is partial.
- **show_progressbar** (*bool*) – (Inherited from angr.Analysis.) Show a progressbar during CFG recovery.
- **force_smart_scan** (*bool | None*)
- **drop_bad_funcs** (*bool*)

Aborting and resuming CFG recovery:

After a graceful abort (see progress_callback above), self.resume_state captures the jobs that were still unprocessed (with their function context) and the unresolved indirect jumps; self.unprocessed_job_addrs holds the corresponding addresses for informational purposes. To resume recovery, create a new CFGFast instance reusing the partial model. To resume global scanning and finish the entire binary, re-inject the captured state while keeping the seeding options (symbols, function_prologues, eh_frame, force_smart_scan) at their original values:

```
proj.analyses.CFGFast(model=partial_cfg.model, start_at_entry=False,
                      resume_state=partial_cfg.resume_state)
```

Do not pass unprocessed_job_addrs as function_starts instead: function_starts seeds are treated as function heads, which would promote unprocessed call return sites and intra-function jump targets to functions.

To only resume from specific addresses (they must not be part of the partial model already; seeding an already-scanned address is a no-op):

```
proj.analyses.CFGFast(model=partial_cfg.model, function_starts=[addr], start_at_
↪entry=False,
                      symbols=False, function_prologues=False, eh_frame=False,
                      force_smart_scan=False, force_complete_scan=False,
                      treat_functions_as_complete=False)
```

treat_functions_as_complete=False tells post-analysis that the resulting model is still partial: functions must not be dropped as bad, and returning=False must not be concluded for (possibly truncated) functions - such conclusions would poison a later full resume the same way an abort would without them being reset.

**Returns**
None

**Parameters**

- **function_prologues** (*bool | None*)
- **force_smart_scan** (*bool | None*)
- **resume_state** (CFGResumeState | *None*)
- **indirect_calls_always_return** (*bool | None*)
- **jumptable_resolver_resolves_calls** (*bool | None*)
- **retedges** (*bool*)
- **drop_bad_funcs** (*bool*)
- **treat_functions_as_complete** (*bool*)

**unprocessed_job_addrs:** set[int]

**resume_state:** *CFGResumeState* | None

**stage:** str

**property graph:** *SpillingCFG*

**property memory_data**

**property jump_tables**

**property insn_addr_to_memory_data**

**do_full_xrefs**(*overlay_state=None*)

Perform xref recovery on all functions.

**Parameters**
**overlay** (SimState) – An overlay state for loading constant data.

**Returns**
None

drop_bad_functions()

make_return_edges()

For each returning function, create return edges in self.graph.

**Returns**
None

copy()

output()

### angr.analyses.cfg.cfg_fast_soot

class angr.analyses.cfg.cfg_fast_soot.**CFGFastSoot**

Bases: *CFGFast*

addr_type: Literal['int', 'block_id', 'soot'] = 'soot'

drop_bad_functions()

make_functions()

Revisit the entire control flow graph, create Function instances accordingly, and correctly put blocks into each function.

Although Function objects are crated during the CFG recovery, they are neither sound nor accurate. With a pre-constructed CFG, this method rebuilds all functions bearing the following rules:

- A block may only belong to one function.
- Small functions lying inside the startpoint and the endpoint of another function will be merged with the other function
- Tail call optimizations are detected.
- PLT stubs are aligned by 16.

**Returns**
None

### angr.analyses.cfg.cfg_job_base

class angr.analyses.cfg.cfg_job_base.**FunctionKey**

Bases: object

A context-sensitive key for a function.

__init__(*addr*, *callsite_tuples*)

callsite_repr()

static new(*addr*, *callsite_tuples*)

class angr.analyses.cfg.cfg_job_base.**CFGJobBase**

Bases: object

Describes an entry in CFG or VFG. Only used internally by the analysis.

__init__(*addr*, *state*, *context_sensitivity_level*, *block_id=None*, *src_block_id=None*, *src_exit_stmt_idx=None*, *src_ins_addr=None*, *jumpkind=None*, *call_stack=None*, *is_narrowing=False*, *skip=False*, *final_return_address=None*)

**Parameters**

- **state** (SimState)
- **jumpkind** (*str | None*)

property call_stack

call_stack_copy()

get_call_stack_suffix()

property func_addr

property current_stack_pointer

### angr.analyses.cfg.go_prologue

Recognition of the Go (gc) goroutine stack-growth preamble.

Every non-nosplit Go function starts with a check of the current stack pointer (or of the prospective frame bottom) against `g.stackguard0`, followed by a forward branch to a `runtime.morestack` trampoline appended after the function body. The conventional prologue the architecture's `function_prologs` describe only comes *after* that check, so a plain prologue scan reports function starts several instructions past the real entry.

`g.stackguard0` sits at `2 * ptrSize` in `g` – `[reg + 0x10]` on 64-bit targets, `[reg + 8]` on 32-bit ones. Functions the compiler marks as C functions (`//go:systemstack` and friends) check `g.stackguard1` instead, one pointer further in. The register holding `g` is architectural on most targets (r14 on amd64, x28 on arm64, r10 on arm), so the compare alone identifies the check. 386 has no dedicated g register and reaches `g` through TLS with an OS-specific sequence, which is therefore part of the pattern there.

The encodings have drifted across releases, so the tables cover several forms per architecture: windows/386 reaches g through `fs:[0x14]` up to go1.20 and through `runtime.tls_g` from go1.21, and the arm64 scratch pair was x1/x2 in go1.17 and is x16/x17 from go1.18 on – where go1.18 still compared through x17 and go1.19 and later compare sp directly.

angr.analyses.cfg.go_prologue.**go_preamble_supported**(*arch_name*)

Whether the Go stack-growth preamble is recognized on the named architecture.

**Return type**
bool

**Parameters**
**arch_name** (*str*)

angr.analyses.cfg.go_prologue.**find_go_stack_check_preambles**(*blob*, *arch_name*, *base=0*)

Find every Go goroutine stack-growth preamble in `blob`.

**Parameters**

- **blob** (bytes) – A blob of machine code.
- **arch_name** (str) – `archinfo` name of the architecture `blob` is code for.
- **base** (int) – The address `blob` starts at, used to enforce instruction alignment.

**Return type**
Iterator[tuple[int, int, int]]

**Returns**
An iterator of `(start, end, branch_target)` offsets into `blob`. Only preambles whose stack-growth branch goes forward are reported; the caller must still check that `branch_target` lies in the same executable region.

### angr.analyses.cfg.indirect_jump_resolvers

**class** angr.analyses.cfg.indirect_jump_resolvers.**AArch64MachOGotResolver**

Bases: *IndirectJumpResolver*

A timeless indirect jump resolver that resolves GOT entries on AArch64 MachO binaries.

**__init__**(*project*)

**resolve**(*cfg*, *addr*, *func_addr*, *block*, *jumpkind*, *func_graph_complete=True*, ***kwargs*)

Resolves the GOT entries in AARCH64 Mach-O binaries, where plt stubs are of manner:

```
adrp    x16, #0x100000
ldr     x16, [x16,#0x10]
br      x16
```

**Parameters**
**func_graph_complete** (*bool*)

**class** angr.analyses.cfg.indirect_jump_resolvers.**AMD64ElfGotResolver**

Bases: *IndirectJumpResolver*

A timeless indirect jump resolver that resolves GOT entries on AMD64 ELF binaries.

**__init__**(*project*)

**class** angr.analyses.cfg.indirect_jump_resolvers.**AMD64PeIatResolver**

Bases: *IndirectJumpResolver*

A timeless indirect call/jump resolver for IAT in amd64 PEs.

**__init__**(*project*)

**class** angr.analyses.cfg.indirect_jump_resolvers.**ArmElfFastResolver**

Bases: *IndirectJumpResolver*

Resolves indirect jumps in ARM ELF binaries

**__init__**(*project*)

**resolve**(*cfg*, *addr*, *func_addr*, *block*, *jumpkind*, *func_graph_complete=True*, ***kwargs*)

The main resolving function.

**Parameters**

- **cfg** – A CFG instance.
- **addr** (*int*) – Address of the IRSB.
- **func_addr** (*int*) – Address of the function.
- **block** – The IRSB.
- **jumpkind** (*str*) – The jumpkind.
- **func_graph_complete** (*bool*)

**Returns**

**Return type**
tuple

class angr.analyses.cfg.indirect_jump_resolvers.**ConstantResolver**

Bases: *IndirectJumpResolver*

Resolve an indirect jump by running a constant propagation on the entire function and check if the indirect jump can be resolved to a constant value. This resolver must be run after all other more specific resolvers.

**__init__**(*project*, *max_func_nodes=512*)

**Parameters**
**max_func_nodes** (*int*)

**resolve**(*cfg*, *addr*, *func_addr*, *block*, *jumpkind*, *func_graph_complete=True*, ***kwargs*)

This function does the actual resolve. Our process is easy: Propagate all values inside the function specified, then extract the tmp_var used for the indirect jump from the basic block. Use the tmp var to locate the constant value stored in the replacements. If not present, returns False tuple.

**Parameters**

- **cfg** – CFG with specified function
- **addr** (int) – Address of indirect jump
- **func_addr** (int) – Address of function of indirect jump
- **block** (*Block*) – Block of indirect jump (Block object)
- **jumpkind** (str) – VEX jumpkind (Ijk_Boring or Ijk_Call)
- **func_graph_complete** (*bool*)

**Returns**
Bool tuple with replacement address

class angr.analyses.cfg.indirect_jump_resolvers.**JumpTableResolver**

Bases: *IndirectJumpResolver*

A generic jump table resolver.

**This is a fast jump table resolution. For performance concerns, we made the following assumptions:**

- The final jump target comes from the memory.
- The final jump target must be directly read out of the memory, without any further modification or altering.

Progressively larger program slices will be analyzed to determine jump table location and size. If the size of the table cannot be determined, a *guess* will be made based on how many entries in the table *appear* valid.

**__init__**(*project*, *resolve_calls=True*)

**Parameters**
**resolve_calls** (*bool*)

**resolve**(*cfg*, *addr*, *func_addr*, *block*, *jumpkind*, *func_graph_complete=True*, ***kwargs*)

Resolves jump tables.

**Parameters**

- **cfg** – A CFG instance.
- **addr** (*int*) – IRSB address.

- **func_addr** (*int*) – The function address.
- **block** (*pyvex.IRSB*) – The IRSB.
- **func_graph_complete** (*bool*)

**Returns**
A bool indicating whether the indirect jump is resolved successfully, and a list of resolved targets

**Return type**
tuple

**class** angr.analyses.cfg.indirect_jump_resolvers.**MemoryLoadResolver**

Bases: *IndirectJumpResolver*

Resolve an indirect jump that looks like the following:

```
.text:
                call    off_3314A8

.data:
off_3314A8      dd offset sub_1E426F
```

This indirect jump resolver may not be the best solution for all cases (e.g., when the .data section can be intentionally altered by the binary itself).

**__init__**(*project*)

**resolve**(*cfg*, *addr*, *func_addr*, *block*, *jumpkind*, *func_graph_complete=True*, ***kwargs*)

**Parameters**

- **cfg** – CFG with specified function
- **addr** (*int*) – Address of indirect jump
- **func_addr** (*int*) – Address of function of indirect jump
- **block** (*IRSB*) – Block of indirect jump (Block object)
- **jumpkind** (*str*) – VEX jumpkind (Ijk_Boring or Ijk_Call)
- **func_graph_complete** (*bool*)

**Returns**
Bool tuple with replacement address

**class** angr.analyses.cfg.indirect_jump_resolvers.**MipsElfFastResolver**

Bases: *IndirectJumpResolver*

A timeless indirect jump resolver for R9-based indirect function calls in MIPS ELFs.

**__init__**(*project*)

**resolve**(*cfg*, *addr*, *func_addr*, *block*, *jumpkind*, *func_graph_complete=True*, ***kwargs*)

Wrapper for _resolve that slowly increments the max_depth used by Blade for finding sources until we can resolve the addr or we reach the default max_depth

**Parameters**

- **cfg** – A CFG instance.
- **addr** (*int*) – IRSB address.

- **func_addr** (*int*) – The function address.
- **block** (*pyvex.IRSB*) – The IRSB.
- **jumpkind** (*str*) – The jumpkind.
- **func_graph_complete** (*bool*)

**Returns**
If it was resolved and targets alongside it

**Return type**
tuple

**class** angr.analyses.cfg.indirect_jump_resolvers.**MipsElfGotResolver**

Bases: *IndirectJumpResolver*

A timeless indirect jump resolver that resolves GOT stub entries in MIPS ELF binaries.

Reference: MIPS Assembly Language Programmer's Guide, Calling Position Independent Functions

**__init__**(*project*)

**class** angr.analyses.cfg.indirect_jump_resolvers.**SyscallResolver**

Bases: *IndirectJumpResolver*

Resolve syscalls to SimProcedures.

**__init__**(*project*)

**class** angr.analyses.cfg.indirect_jump_resolvers.**X86ElfPicPltResolver**

Bases: *IndirectJumpResolver*

In X86 ELF position-independent code, PLT stubs uses ebx to resolve library calls, where ebx stores the address to the beginning of the GOT. We resolve the target by forcing ebx to be the beginning of the GOT and simulate the execution in fast path mode.

**__init__**(*project*)

**class** angr.analyses.cfg.indirect_jump_resolvers.**X86PeIatResolver**

Bases: *IndirectJumpResolver*

A timeless indirect jump resolver for IAT in x86 PEs and xbes.

**__init__**(*project*)

### angr.analyses.cfg.indirect_jump_resolvers.aarch64_macho_got

**class** angr.analyses.cfg.indirect_jump_resolvers.aarch64_macho_got.**AArch64MachOGotResolver**

Bases: *IndirectJumpResolver*

A timeless indirect jump resolver that resolves GOT entries on AArch64 MachO binaries.

**__init__**(*project*)

**resolve**(*cfg*, *addr*, *func_addr*, *block*, *jumpkind*, *func_graph_complete=True*, ***kwargs*)

Resolves the GOT entries in AARCH64 Mach-O binaries, where plt stubs are of manner:

```
adrp    x16, #0x100000
ldr     x16, [x16,#0x10]
br      x16
```

**Parameters**

**func_graph_complete** (*bool*)

### angr.analyses.cfg.indirect_jump_resolvers.amd64_elf_got

**class** angr.analyses.cfg.indirect_jump_resolvers.amd64_elf_got.**AMD64ElfGotResolver**

Bases: *IndirectJumpResolver*

A timeless indirect jump resolver that resolves GOT entries on AMD64 ELF binaries.

**__init__**(*project*)

### angr.analyses.cfg.indirect_jump_resolvers.amd64_pe_iat

**class** angr.analyses.cfg.indirect_jump_resolvers.amd64_pe_iat.**AMD64PeIatResolver**

Bases: *IndirectJumpResolver*

A timeless indirect call/jump resolver for IAT in amd64 PEs.

**__init__**(*project*)

### angr.analyses.cfg.indirect_jump_resolvers.arm_elf_fast

**class** angr.analyses.cfg.indirect_jump_resolvers.arm_elf_fast.**ArmElfFastResolver**

Bases: *IndirectJumpResolver*

Resolves indirect jumps in ARM ELF binaries

**__init__**(*project*)

**resolve**(*cfg*, *addr*, *func_addr*, *block*, *jumpkind*, *func_graph_complete=True*, ***kwargs*)

The main resolving function.

**Parameters**

- **cfg** – A CFG instance.
- **addr** (*int*) – Address of the IRSB.
- **func_addr** (*int*) – Address of the function.
- **block** – The IRSB.
- **jumpkind** (*str*) – The jumpkind.
- **func_graph_complete** (*bool*)

**Returns**

**Return type**
tuple

### angr.analyses.cfg.indirect_jump_resolvers.const_resolver

angr.analyses.cfg.indirect_jump_resolvers.const_resolver.**exists_in_replacements**(*replacements*, *block_loc*, *tmp_var*)

**class** angr.analyses.cfg.indirect_jump_resolvers.const_resolver.**ConstantResolver**

Bases: *IndirectJumpResolver*

Resolve an indirect jump by running a constant propagation on the entire function and check if the indirect jump can be resolved to a constant value. This resolver must be run after all other more specific resolvers.

**__init__**(*project*, *max_func_nodes=512*)

**Parameters**
**max_func_nodes** (*int*)

**resolve**(*cfg*, *addr*, *func_addr*, *block*, *jumpkind*, *func_graph_complete=True*, ***kwargs*)

This function does the actual resolve. Our process is easy: Propagate all values inside the function specified, then extract the tmp_var used for the indirect jump from the basic block. Use the tmp var to locate the constant value stored in the replacements. If not present, returns False tuple.

**Parameters**

- **cfg** – CFG with specified function
- **addr** (*int*) – Address of indirect jump
- **func_addr** (*int*) – Address of function of indirect jump
- **block** (*Block*) – Block of indirect jump (Block object)
- **jumpkind** (*str*) – VEX jumpkind (Ijk_Boring or Ijk_Call)
- **func_graph_complete** (*bool*)

**Returns**
Bool tuple with replacement address

### angr.analyses.cfg.indirect_jump_resolvers.constant_value_manager

**class** angr.analyses.cfg.indirect_jump_resolvers.constant_value_manager.**ConstantValueManager**

Bases: object

Manages the loading of registers who hold constant values.

**__init__**(*project*, *kb*, *func*, *ij_addr*)

**Parameters**

- **project** (Project)
- **func** (Function)
- **ij_addr** (*int*)

**project**

**kb**

**func**

**indirect_jump_addr**

**mapping:** dict[Any, dict[Any, Base]] | None

**reg_read_callback**(*state*)

**Parameters**
**state** (SimState)

### angr.analyses.cfg.indirect_jump_resolvers.default_resolvers

angr.analyses.cfg.indirect_jump_resolvers.default_resolvers.**default_indirect_jump_resolvers**(*obj*, *project*)

### angr.analyses.cfg.indirect_jump_resolvers.jumptable

angr.analyses.cfg.indirect_jump_resolvers.jumptable.**has_niche_decoded_index**(*irsb*)

Check if the block computes `idx = (x <s 0) ? x ^ SIGN_BIT : C`, which is how rustc decodes a niche-encoded enum discriminant (e.g., serde_json::Value) into a jump table index. `x ^ SIGN_BIT` is unbounded in the code; the compiler knows the valid niche values, so the table size must come from the data.

**Return type**
bool

**Parameters**
**irsb** (*IRSB*)

**exception** angr.analyses.cfg.indirect_jump_resolvers.jumptable.**NotAJumpTableNotification**

Bases: *AngrError*

Exception raised to indicate this is not (or does not appear to be) a jump table.

**class** angr.analyses.cfg.indirect_jump_resolvers.jumptable.**UninitReadMeta**

Bases: object

Uninitialized read remapping details.

**uninit_read_base = 201326592**

**class** angr.analyses.cfg.indirect_jump_resolvers.jumptable.**AddressTransformationTypes**

Bases: int, Enum

Address transformation operations.

**Assignment = 0**

**SignedExtension = 1**

**UnsignedExtension = 2**

**Truncation = 3**

**Or1 = 4**

**ShiftLeft = 5**

**ShiftRight = 6**

**Add = 7**

**Load = 8**

**__new__**(*value*)

**class** angr.analyses.cfg.indirect_jump_resolvers.jumptable.**AddressTransformation**

Bases: object

Describe and record an address transformation operation.

**__init__**(*op*, *operands*, *first_load=False*)

**Parameters**

- **op** (AddressTransformationTypes)
- **operands** (*list*)
- **first_load** (*bool*)

**class** angr.analyses.cfg.indirect_jump_resolvers.jumptable.**AddressOperand**

Bases: object

The class for the singleton class AddressSingleton. It represents the address being transformed before using as an indirect jump target.

**class** angr.analyses.cfg.indirect_jump_resolvers.jumptable.**Tmp**

Bases: object

For modeling Tmp variables.

**__init__**(*tmp_idx*)

**class** angr.analyses.cfg.indirect_jump_resolvers.jumptable.**JumpTargetBaseAddr**

Bases: object

Model for jump targets and their data origin.

__init__(*stmt_loc*, *stmt*, *tmp*, *base_addr=None*, *tmp_1=None*)

**Parameters**

- **stmt** (*IRStmt*)
- **tmp** (*int*)
- **base_addr** (*int | None*)
- **tmp_1** (*int | None*)

**property base_addr_available**

class angr.analyses.cfg.indirect_jump_resolvers.jumptable.**JumpTableProcessorState**

Bases: object

The state used in JumpTableProcessor.

__init__(*arch*)

**arch**

**is_jumptable: bool | None**

**stmts_to_instrument**

**regs_to_initialize**

class angr.analyses.cfg.indirect_jump_resolvers.jumptable.**RegOffsetAnnotation**

Bases: Annotation

Register Offset annotation.

**relocatable = False**

**eliminatable = False**

__init__(*reg_offset*)

**Parameters**

**reg_offset** (RegisterOffset)

**reg_offset**

class angr.analyses.cfg.indirect_jump_resolvers.jumptable.**JumpTableProcessor**

Bases: *SimEngineNostmtVEX*[*JumpTableProcessorState*, BV, *JumpTableProcessorState*], *ClaripyDataVEXEngineMixin*[*JumpTableProcessorState*, BV, *JumpTableProcessorState*, None]

Implements a simple and stupid data dependency tracking for stack and register variables.

Also determines which statements to instrument during static execution of the slice later. For example, the following example is not uncommon in non-optimized binaries:

```
    mov  [rbp+var_54], 1
loc_4051a6:
    cmp  [rbp+var_54], 6
    ja   loc_405412 (default)
loc_4051b0:
    mov  eax, [rbp+var_54]
    mov  rax, qword [rax*8+0x223a01]
    jmp  rax
```

We want to instrument the first instruction and replace the constant 1 with a symbolic variable, otherwise we will not be able to recover all jump targets later in block 0x4051b0.

**__init__**(*project*, *indirect_jump_node_pred_addrs*, *bp_sp_diff=256*)

**Parameters**
**indirect_jump_node_pred_addrs** (*set[int]*)

**class** angr.analyses.cfg.indirect_jump_resolvers.jumptable.**StoreHook**

Bases: object

Hook for memory stores.

**static hook**(*state*)

**class** angr.analyses.cfg.indirect_jump_resolvers.jumptable.**LoadHook**

Bases: object

Hook for memory loads.

**__init__**()

**hook_before**(*state*)

**hook_after**(*state*)

**class** angr.analyses.cfg.indirect_jump_resolvers.jumptable.**PutHook**

Bases: object

Hook for register writes.

**static hook**(*state*)

**class** angr.analyses.cfg.indirect_jump_resolvers.jumptable.**ShrBoundsConstraintHook**

Bases: object

Hook for rewriting folded bound-check constraints.

libVEX 3.27+ spechelpers fold the unsigned bound check *x <=u 2**k-1* into *Shr(x, k) == 0*. The VSA constraint handler keys its replacement on the LShR expression instead of x itself, so the bound never narrows x (and thus the jump table address) during slice execution. Rewrite such constraints into the canonical ULE/UGT form.

**static hook**(*state*)

**class** angr.analyses.cfg.indirect_jump_resolvers.jumptable.**RegisterInitializerHook**

Bases: object

Hook for register init.

**__init__**(*reg_offset*, *reg_bits*, *initial_value*)

**hook**(*state*)

**class** angr.analyses.cfg.indirect_jump_resolvers.jumptable.**BSSHook**

Bases: object

Hook for BSS read/write.

**__init__**(*project*, *bss_regions*)

**bss_memory_read_hook**(*state*)

**bss_memory_write_hook**(*state*)

class angr.analyses.cfg.indirect_jump_resolvers.jumptable.**MIPSGPHook**

Bases: object

Hooks all reads from and writes into the gp register for MIPS32 binaries.

**__init__**(*gp_offset*, *gp*)

**Parameters**

- **gp_offset** (*int*)
- **gp** (*int*)

**gp_register_read_hook**(*state*)

**gp_register_write_hook**(*state*)

class angr.analyses.cfg.indirect_jump_resolvers.jumptable.**JumpTableResolver**

Bases: *IndirectJumpResolver*

A generic jump table resolver.

**This is a fast jump table resolution. For performance concerns, we made the following assumptions:**

- The final jump target comes from the memory.
- The final jump target must be directly read out of the memory, without any further modification or altering.

Progressively larger program slices will be analyzed to determine jump table location and size. If the size of the table cannot be determined, a *guess* will be made based on how many entries in the table *appear* valid.

**__init__**(*project*, *resolve_calls=True*)

**Parameters**
**resolve_calls** (*bool*)

**resolve**(*cfg*, *addr*, *func_addr*, *block*, *jumpkind*, *func_graph_complete=True*, ***kwargs*)

Resolves jump tables.

**Parameters**

- **cfg** – A CFG instance.
- **addr** (*int*) – IRSB address.
- **func_addr** (*int*) – The function address.
- **block** (*pyvex.IRSB*) – The IRSB.
- **func_graph_complete** (*bool*)

**Returns**
A bool indicating whether the indirect jump is resolved successfully, and a list of resolved targets

**Return type**
tuple

### angr.analyses.cfg.indirect_jump_resolvers.memload_resolver

**class** angr.analyses.cfg.indirect_jump_resolvers.memload_resolver.**MemoryLoadResolver**

Bases: *IndirectJumpResolver*

Resolve an indirect jump that looks like the following:

```
.text:
                call    off_3314A8

.data:
off_3314A8      dd offset sub_1E426F
```

This indirect jump resolver may not be the best solution for all cases (e.g., when the .data section can be intentionally altered by the binary itself).

**__init__**(*project*)

**resolve**(*cfg*, *addr*, *func_addr*, *block*, *jumpkind*, *func_graph_complete=True*, ***kwargs*)

**Parameters**

- **cfg** – CFG with specified function
- **addr** (int) – Address of indirect jump
- **func_addr** (int) – Address of function of indirect jump
- **block** (IRSB) – Block of indirect jump (Block object)
- **jumpkind** (str) – VEX jumpkind (Ijk_Boring or Ijk_Call)
- **func_graph_complete** (*bool*)

**Returns**

Bool tuple with replacement address

### angr.analyses.cfg.indirect_jump_resolvers.mips_elf_fast

angr.analyses.cfg.indirect_jump_resolvers.mips_elf_fast.**enable_profiling**()

angr.analyses.cfg.indirect_jump_resolvers.mips_elf_fast.**disable_profiling**()

**class** angr.analyses.cfg.indirect_jump_resolvers.mips_elf_fast.**Case2Result**

Bases: Enum

Describes the result of resolving case 2 function calls.

**SUCCESS = 0**

**FAILURE = 1**

**RESUME = 2**

**class** angr.analyses.cfg.indirect_jump_resolvers.mips_elf_fast.**MipsElfFastResolver**

Bases: *IndirectJumpResolver*

A timeless indirect jump resolver for R9-based indirect function calls in MIPS ELFs.

**__init__**(*project*)

**resolve**(*cfg*, *addr*, *func_addr*, *block*, *jumpkind*, *func_graph_complete=True*, ***kwargs*)

Wrapper for _resolve that slowly increments the max_depth used by Blade for finding sources until we can resolve the addr or we reach the default max_depth

**Parameters**

- **cfg** – A CFG instance.
- **addr** (*int*) – IRSB address.
- **func_addr** (*int*) – The function address.
- **block** (*pyvex.IRSB*) – The IRSB.
- **jumpkind** (*str*) – The jumpkind.
- **func_graph_complete** (*bool*)

**Returns**
If it was resolved and targets alongside it

**Return type**
tuple

### angr.analyses.cfg.indirect_jump_resolvers.mips_elf_got

**class** angr.analyses.cfg.indirect_jump_resolvers.mips_elf_got.**MipsElfGotResolver**

Bases: *IndirectJumpResolver*

A timeless indirect jump resolver that resolves GOT stub entries in MIPS ELF binaries.

Reference: MIPS Assembly Language Programmer's Guide, Calling Position Independent Functions

**__init__**(*project*)

### angr.analyses.cfg.indirect_jump_resolvers.propagator_utils

**class** angr.analyses.cfg.indirect_jump_resolvers.propagator_utils.**PropagatorLoadCallback**

Bases: object

Implement the load callback for Propagator that should be used across all jump table resolvers.

**__init__**(*project*)

**propagator_load_callback**(*addr*, *size*)

**Return type**
bool

**Parameters**

- **addr** (*BV | int*)
- **size** (*int*)

### angr.analyses.cfg.indirect_jump_resolvers.resolver

**class** angr.analyses.cfg.indirect_jump_resolvers.resolver.**IndirectJumpResolver**

Bases: object

**__init__**(*project*, *timeless=False*, *base_state=None*)

**filter**(*cfg*, *addr*, *func_addr*, *block*, *jumpkind*)

Check if this resolution method may be able to resolve the indirect jump or not.

**Parameters**

- **addr** (*int*) – Basic block address of this indirect jump.
- **func_addr** (*int*) – Address of the function that this indirect jump belongs to.
- **block** – The basic block. The type is determined by the backend being used. It's pyvex.IRSB if pyvex is used as the backend.
- **jumpkind** (*str*) – The jumpkind.

**Returns**

True if it is possible for this resolution method to resolve the specific indirect jump, False otherwise.

**Return type**

bool

**resolve**(*cfg*, *addr*, *func_addr*, *block*, *jumpkind*, *func_graph_complete=True*, ***kwargs*)

Resolve an indirect jump.

**Parameters**

- **cfg** – The CFG analysis object.
- **addr** (*int*) – Basic block address of this indirect jump.
- **func_addr** (*int*) – Address of the function that this indirect jump belongs to.
- **block** – The basic block. The type is determined by the backend being used. It's pyvex.IRSB if pyvex is used as the backend.
- **jumpkind** (*str*) – The jumpkind.
- **func_graph_complete** (*bool*) – True if the function graph is complete at this point (except for nodes that this indirect jump node dominates).

**Returns**

A tuple of a boolean indicating whether the resolution is successful or not, and a list of resolved targets (ints).

**Return type**

tuple

### angr.analyses.cfg.indirect_jump_resolvers.syscall_resolver

**class** angr.analyses.cfg.indirect_jump_resolvers.syscall_resolver.**SyscallResolver**

Bases: *IndirectJumpResolver*

Resolve syscalls to SimProcedures.

**__init__**(*project*)

### angr.analyses.cfg.indirect_jump_resolvers.x86_elf_pic_plt

**class** angr.analyses.cfg.indirect_jump_resolvers.x86_elf_pic_plt.**X86ElfPicPltResolver**

Bases: *IndirectJumpResolver*

In X86 ELF position-independent code, PLT stubs uses ebx to resolve library calls, where ebx stores the address to the beginning of the GOT. We resolve the target by forcing ebx to be the beginning of the GOT and simulate the execution in fast path mode.

**__init__**(*project*)

### angr.analyses.cfg.indirect_jump_resolvers.x86_pe_iat

**class** angr.analyses.cfg.indirect_jump_resolvers.x86_pe_iat.**X86PeIatResolver**

Bases: *IndirectJumpResolver*

A timeless indirect jump resolver for IAT in x86 PEs and xbes.

**__init__**(*project*)

### angr.analyses.cfg.meta_structs

angr.analyses.cfg.meta_structs.**get_data_regions_from_meta_regions**(*loader*)

Extract (addr, size, sort) tuples for all metadata data regions across all loaded objects.

Flattens DataDirectory sub-regions so each entry maps to a contiguous memory range suitable for marking in CFGFast's _seg_list.

**Return type**
list[tuple[int, int, str | None]]

**Parameters**
**loader** (*Loader*)

angr.analyses.cfg.meta_structs.**get_function_hints_from_meta_regions**(*loader*)

Extract (addr, name) pairs for functions discovered from metadata.

Uses meta_function_hints populated by backends (e.g., PE export table entries).

**Return type**
list[tuple[int, str | None]]

**Parameters**
**loader** (*Loader*)

angr.analyses.cfg.meta_structs.**get_pointer_array_hints**(*loader*)

Extract pointer array hints and return tuples of (addr, byte count) for each pointer array.

**Return type**
list[tuple[int, int]]

**Parameters**
**loader** (*Loader*)

angr.analyses.cfg.meta_structs.**get_pointer_array_hints_pe**(*pe*)

Extract pointer array hints from a PE object and return tuples of (addr, byte count) for each pointer array.

**Return type**
list[tuple[int, int]]

**Parameters**
**pe** (*PE*)

### angr.analyses.cfg.pe_msvc_eh_structs

Struct definitions and parsing utilities for MSVC C++ exception handling structures found in x86 PE binaries.

References: - ___CxxFrameHandler3: The MSVC C++ exception handler for 32-bit binaries. - __EH_prolog3 / __EH_prolog3_catch / __EH_prolog3_GS: C++ EH prolog helpers. - __SEH_prolog4 / __SEH_prolog4_GS: SEH prolog helpers. - FuncInfo: Describes exception handling metadata for a function. - UnwindMapEntry: Describes state unwinding actions during exception handling.

**class** angr.analyses.cfg.pe_msvc_eh_structs.**FuncInfo**

Bases: object

Parsed FuncInfo struct from a 32-bit PE binary.

**__init__**(*addr*, *magic_number*, *max_state*, *p_unwind_map*, *n_try_blocks*, *p_try_block_map*, *n_ip_map_entries*, *p_ip_to_state_map*, *p_es_type_list*, *eh_flags*)

**Parameters**

- **addr** (*int*)
- **magic_number** (*int*)
- **max_state** (*int*)
- **p_unwind_map** (*int*)
- **n_try_blocks** (*int*)
- **p_try_block_map** (*int*)
- **n_ip_map_entries** (*int*)
- **p_ip_to_state_map** (*int*)
- **p_es_type_list** (*int*)
- **eh_flags** (*int*)

**addr**

**magic_number**

**max_state**

**p_unwind_map**

**n_try_blocks**

**p_try_block_map**

**n_ip_map_entries**

**p_ip_to_state_map**

**p_es_type_list**

**eh_flags**

**class** angr.analyses.cfg.pe_msvc_eh_structs.**UnwindMapEntry**

Bases: object

Parsed UnwindMapEntry struct from a 32-bit PE binary.

__init__(*addr*, *to_state*, *action*)

**Parameters**

- **addr** (*int*)
- **to_state** (*int*)
- **action** (*int*)

**addr**

**to_state**

**action**

angr.analyses.cfg.pe_msvc_eh_structs.**parse_funcinfo**(*memory*, *addr*)

Parse a FuncInfo struct at the given address.

**Parameters**

- **memory** – The loader memory interface (supports .load(addr, size)).
- **addr** (int) – The virtual address of the FuncInfo struct.

**Return type**

*FuncInfo* | None

**Returns**

A FuncInfo object, or None if parsing fails.

class angr.analyses.cfg.pe_msvc_eh_structs.**EH4ScopeTable**

Bases: object

Parsed _EH4_SCOPETABLE struct from a 32-bit PE binary.

__init__(*addr*, *gs_cookie_offset*, *gs_cookie_xor_offset*, *eh_cookie_offset*, *eh_cookie_xor_offset*, *records*)

**Parameters**

- **addr** (*int*)
- **gs_cookie_offset** (*int*)
- **gs_cookie_xor_offset** (*int*)
- **eh_cookie_offset** (*int*)
- **eh_cookie_xor_offset** (*int*)
- **records** (*list*[EH4ScopeRecord])

**addr**

**gs_cookie_offset**

**gs_cookie_xor_offset**

**eh_cookie_offset**

**eh_cookie_xor_offset**

**records**

**property total_size: int**

class angr.analyses.cfg.pe_msvc_eh_structs.**EH4ScopeRecord**

Bases: object

Parsed _EH4_SCOPETABLE_RECORD struct from a 32-bit PE binary.

**__init__**(*enclosing_level*, *filter_func*, *handler_func*)

**Parameters**

- **enclosing_level** (*int*)
- **filter_func** (*int*)
- **handler_func** (*int*)

**enclosing_level**

**filter_func**

**handler_func**

angr.analyses.cfg.pe_msvc_eh_structs.**parse_eh4_scopetable**(*memory*, *addr*, *code_range=None*)

Parse an _EH4_SCOPETABLE at the given address.

**Parameters**

- **memory** – The loader memory interface.
- **addr** (int) – The virtual address of the _EH4_SCOPETABLE.
- **code_range** (tuple[int, int] | None) – Optional (min_addr, max_addr) of executable memory. When provided, FilterFunc and HandlerFunc pointers are validated against this range.

**Return type**

*EH4ScopeTable* | None

**Returns**

An EH4ScopeTable object, or None if parsing fails.

angr.analyses.cfg.pe_msvc_eh_structs.**parse_unwind_map**(*memory*, *addr*, *count*)

Parse an array of UnwindMapEntry structs.

**Parameters**

- **memory** – The loader memory interface.
- **addr** (int) – The virtual address of the first UnwindMapEntry.
- **count** (int) – The number of entries (maxState from FuncInfo).

**Return type**

list[*UnwindMapEntry*]

**Returns**

A list of UnwindMapEntry objects.

class angr.analyses.cfg.pe_msvc_eh_structs.**TryBlockMapEntry**

Bases: object

Parsed TryBlockMapEntry struct from a 32-bit PE binary.

__init__(*addr*, *try_low*, *try_high*, *catch_high*, *n_catches*, *p_handler_array*, *handlers*)

**Parameters**

- **addr** (*int*)
- **try_low** (*int*)
- **try_high** (*int*)
- **catch_high** (*int*)
- **n_catches** (*int*)
- **p_handler_array** (*int*)
- **handlers** (*list[HandlerType]*)

**addr**

**try_low**

**try_high**

**catch_high**

**n_catches**

**p_handler_array**

**handlers**

class angr.analyses.cfg.pe_msvc_eh_structs.**HandlerType**

Bases: object

Parsed HandlerType struct from a 32-bit PE binary.

__init__(*addr*, *adjectives*, *p_type*, *disp_catch_obj*, *address_of_handler*)

**Parameters**

- **addr** (*int*)
- **adjectives** (*int*)
- **p_type** (*int*)
- **disp_catch_obj** (*int*)
- **address_of_handler** (*int*)

**addr**

**adjectives**

**p_type**

**disp_catch_obj**

**address_of_handler**

angr.analyses.cfg.pe_msvc_eh_structs.**parse_handler_array**(*memory*, *addr*, *count*)

Parse an array of HandlerType structs.

**Parameters**

- **memory** – The loader memory interface.
- **addr** (int) – The virtual address of the first HandlerType.
- **count** (int) – The number of entries (nCatches from TryBlockMapEntry).

**Return type**
list[*HandlerType*]

**Returns**
A list of HandlerType objects.

angr.analyses.cfg.pe_msvc_eh_structs.**parse_try_block_map**(*memory*, *addr*, *count*)

Parse an array of TryBlockMapEntry structs, including their nested HandlerType arrays.

**Parameters**

- **memory** – The loader memory interface.
- **addr** (int) – The virtual address of the first TryBlockMapEntry.
- **count** (int) – The number of entries (nTryBlocks from FuncInfo).

**Return type**
list[*TryBlockMapEntry*]

**Returns**
A list of TryBlockMapEntry objects.

### 10.3.10 angr.analyses.cfg_slice_to_sink

**class** angr.analyses.cfg_slice_to_sink.**CFGSliceToSink**

Bases: object

The representation of a slice of a CFG.

**__init__**(*target*, *transitions=None*)

**Parameters**

- **target** (angr.knowledge_plugins.functions.function.Function) – The targeted sink, to which every path in the slice leads.
- **transitions** (*Dict[int,List[int]]*) – A mapping representing transitions in the graph. Indexes are source addresses and values a list of destination addresses, for which there exists a transition in the slice from source to destination.

**property transitions**

The transitions in the slice.

**Type**
return Dict[int,List[int]]

**property transitions_as_tuples**

The list of transitions as pairs of (source, destination).

**Type**
return List[Tuple[int,int]]

**property target**

return angr.knowledge_plugins.functions.function.Function: The targeted sink function, from which the slice is constructed.

**property nodes: list[int]**

The complete list of addresses present in the slice.

**Type**
return

**property entrypoints**

Entrypoints are all source addresses that are not the destination address of any transition.

**Return List[int]**
The list of entrypoints addresses.

**add_transitions**(*transitions*)

Add the given transitions to the current slice.

**Parameters**
**transitions** (*Dict[int,List[int]]*) – The list of transitions to be added to *self.transitions*.

**Return Dict[int,List[int]]**
Return the updated list of transitions.

**is_empty**()

Test if a given slice does not contain any transition.

**Return bool**
True if the <CFGSliceToSink> instance does not contain any transitions. False otherwise.

**path_between**(*source*, *destination*, *visited=None*)

Check the existence of a path in the slice between two given node addresses.

**Parameters**

- **source** (int) – The source address.
- **destination** (int) – The destination address.
- **visited** (set[Any] | None) – Used to avoid infinite recursion if loops are present in the slice.

**Return type**
bool

**Returns**
True if there is a path between the source and the destination in the CFG, False if not, or if we have been unable to decide (because of loops).

angr.analyses.cfg_slice_to_sink.**slice_callgraph**(*callgraph*, *cfg_slice_to_sink*)

Slice a callgraph, keeping only the nodes present in the <CFGSliceToSink> representation, and th transitions for which a path exists.

*Note* that this function mutates the graph passed as an argument.

**Parameters**

- **callgraph** (*networkx.MultiDiGraph*) – The callgraph to update.
- **cfg_slice_to_sink** (CFGSliceToSink) – The representation of the slice, containing the data to update the callgraph from.

angr.analyses.cfg_slice_to_sink.**slice_cfg_graph**(*graph*, *cfg_slice_to_sink*)

Slice a CFG graph, keeping only the transitions and nodes present in the <CFGSliceToSink> representation.

*Note* that this function mutates the graph passed as an argument.

**Parameters**

- **graph** (*networkx.DiGraph*) – The graph to slice.
- **cfg_slice_to_sink** (CFGSliceToSink) – The representation of the slice, containing the data to update the CFG from.

**Return networkx.DiGraph**
The sliced graph.

angr.analyses.cfg_slice_to_sink.**slice_function_graph**(*function_graph*, *cfg_slice_to_sink*)

Slice a function graph, keeping only the nodes present in the <CFGSliceToSink> representation.

Because the <CFGSliceToSink> is build from the CFG, and the function graph is *NOT* a subgraph of the CFG, edges of the function graph will no be present in the <CFGSliceToSink> transitions. However, we use the fact that if there is an edge between two nodes in the function graph, then there must exist a path between these two nodes in the slice; Proof idea: - The <CFGSliceToSink> is backward and recursively constructed; - If a node is in the slice, then all its predecessors will be (transitively); - If there is an edge between two nodes in the function graph, there is a path between them in the CFG; - So: The origin node is a transitive predecessor of the destination one, hence if destination is in the slice, then origin will be too.

In consequence, in the end, removing the only nodes not present in the slice, and their related transitions gives us the expected result: a function graph representing (a higher view of) the flow in the slice.

*Note* that this function mutates the graph passed as an argument.

**Parameters**

- **graph** (*networkx.DiGraph*) – The graph to slice.
- **cfg_slice_to_sink** (CFGSliceToSink) – The representation of the slice, containing the data to update the CFG from.

**Return networkx.DiGraph**
The sliced graph.

### angr.analyses.cfg_slice_to_sink.cfg_slice_to_sink

**class** angr.analyses.cfg_slice_to_sink.cfg_slice_to_sink.**CFGSliceToSink**

Bases: object

The representation of a slice of a CFG.

**__init__**(*target*, *transitions=None*)

**Parameters**

- **target** (angr.knowledge_plugins.functions.function.Function) – The targeted sink, to which every path in the slice leads.

- **transitions** (*Dict[int,List[int]]*) – A mapping representing transitions in the graph. Indexes are source addresses and values a list of destination addresses, for which there exists a transition in the slice from source to destination.

**property transitions**

The transitions in the slice.

**Type**
return Dict[int,List[int]]

**property transitions_as_tuples**

The list of transitions as pairs of (source, destination).

**Type**
return List[Tuple[int,int]]

**property target**

return angr.knowledge_plugins.functions.function.Function: The targeted sink function, from which the slice is constructed.

**property nodes: list[int]**

The complete list of addresses present in the slice.

**Type**
return

**property entrypoints**

Entrypoints are all source addresses that are not the destination address of any transition.

**Return List[int]**
The list of entrypoints addresses.

**add_transitions**(*transitions*)

Add the given transitions to the current slice.

**Parameters**
**transitions** (*Dict[int,List[int]]*) – The list of transitions to be added to *self.transitions*.

**Return Dict[int,List[int]]**
Return the updated list of transitions.

**is_empty**()

Test if a given slice does not contain any transition.

**Return bool**
True if the <CFGSliceToSink> instance does not contain any transitions. False otherwise.

**path_between**(*source*, *destination*, *visited=None*)

Check the existence of a path in the slice between two given node addresses.

**Parameters**

- **source** (int) – The source address.
- **destination** (int) – The destination address.
- **visited** (set[Any] | None) – Used to avoid infinite recursion if loops are present in the slice.

**Return type**
bool

**Returns**
True if there is a path between the source and the destination in the CFG, False if not, or if we have been unable to decide (because of loops).

### angr.analyses.cfg_slice_to_sink.graph

angr.analyses.cfg_slice_to_sink.graph.**slice_callgraph**(*callgraph*, *cfg_slice_to_sink*)

Slice a callgraph, keeping only the nodes present in the <CFGSliceToSink> representation, and th transitions for which a path exists.

*Note* that this function mutates the graph passed as an argument.

**Parameters**

- **callgraph** (*networkx.MultiDiGraph*) – The callgraph to update.
- **cfg_slice_to_sink** (CFGSliceToSink) – The representation of the slice, containing the data to update the callgraph from.

angr.analyses.cfg_slice_to_sink.graph.**slice_cfg_graph**(*graph*, *cfg_slice_to_sink*)

Slice a CFG graph, keeping only the transitions and nodes present in the <CFGSliceToSink> representation.

*Note* that this function mutates the graph passed as an argument.

**Parameters**

- **graph** (*networkx.DiGraph*) – The graph to slice.
- **cfg_slice_to_sink** (CFGSliceToSink) – The representation of the slice, containing the data to update the CFG from.

**Return networkx.DiGraph**
The sliced graph.

angr.analyses.cfg_slice_to_sink.graph.**slice_function_graph**(*function_graph*, *cfg_slice_to_sink*)

Slice a function graph, keeping only the nodes present in the <CFGSliceToSink> representation.

Because the <CFGSliceToSink> is build from the CFG, and the function graph is *NOT* a subgraph of the CFG, edges of the function graph will no be present in the <CFGSliceToSink> transitions. However, we use the fact that if there is an edge between two nodes in the function graph, then there must exist a path between these two nodes in the slice; Proof idea: - The <CFGSliceToSink> is backward and recursively constructed; - If a node is in the slice, then all its predecessors will be (transitively); - If there is an edge between two nodes in the function graph, there is a path between them in the CFG; - So: The origin node is a transitive predecessor of the destination one, hence if destination is in the slice, then origin will be too.

In consequence, in the end, removing the only nodes not present in the slice, and their related transitions gives us the expected result: a function graph representing (a higher view of) the flow in the slice.

*Note* that this function mutates the graph passed as an argument.

**Parameters**

- **graph** (*networkx.DiGraph*) – The graph to slice.
- **cfg_slice_to_sink** (CFGSliceToSink) – The representation of the slice, containing the data to update the CFG from.

**Return networkx.DiGraph**
The sliced graph.

#### angr.analyses.cfg_slice_to_sink.transitions

**Some utilitary functions to manage our representation of transitions:**
A dictionary, indexed by int (source addresses), which values are list of ints (target addresses).

angr.analyses.cfg_slice_to_sink.transitions.**merge_transitions**(*transitions*, *existing_transitions*)

Merge two dictionaries of transitions together.

**Parameters**

- **transitions** (*Dict[int,List[int]]*) – Some transitions.
- **existing_transitions** (*Dict[int,List[int]]*) – Other transitions.

**Return Dict[int,List[int]]**
The merge of the two parameters.

### 10.3.11 angr.analyses.class_identifier

**class** angr.analyses.class_identifier.**ClassIdentifier**

Bases: *Analysis*

This is a class identifier for non stripped or partially stripped binaries, it identifies classes based on the demangled function names, and also assigns functions to their respective classes based on their names. It also uses the results from the VtableFinder analysis to assign the corresponding vtable to the classes.

self.classes contains a mapping between class names and SimCppClass objects

e.g. A::tool() and A::qux() belong to the class A

**__init__**()

### 10.3.12 angr.analyses.code_tagging

**class** angr.analyses.code_tagging.**CodeTags**

Bases: object

**HAS_XOR = 'HAS_XOR'**

**HAS_BITSHIFTS = 'HAS_BITSHIFTS'**

**HAS_SQL = 'HAS_SQL'**

**LARGE_SWITCH = 'LARGE_SWITCH'**

**class** angr.analyses.code_tagging.**CodeTagging**

Bases: *Analysis*

**__init__**(*func*)

**analyze**()

**has_xor**()

Detects if there is any xor operation in the function.

**Returns**
Tags

**has_bitshifts**()

Detects if there is any bitwise operation in the function.

**Returns**
Tags.

**has_sql**()

Detects if there is any reference to strings that look like SQL queries.

### 10.3.13 angr.analyses.codecave

**class** angr.analyses.codecave.**CodeCaveClassification**

Bases: Enum

Type of code caves.

**ALIGNMENT = 1**

**UNREACHABLE = 2**

**class** angr.analyses.codecave.**CodeCave**

Bases: object

Describes a code cave in a binary.

**func:** *Function* | None

**addr:** int

**size:** int

**classification:** *CodeCaveClassification*

**__init__**(*func*, *addr*, *size*, *classification*)

**Parameters**

- **func** (Function | *None*)
- **addr** (*int*)
- **size** (*int*)
- **classification** (CodeCaveClassification)

**Return type**
None

**class** angr.analyses.codecave.**CodeCaveAnalysis**

Bases: *Analysis*

Best-effort static location of potential vacant code caves for possible code injection: - Padding functions - Unreachable code

**__init__**()

**codecaves:** list[*CodeCave*]

### 10.3.14 angr.analyses.complete_calling_conventions

**class** angr.analyses.complete_calling_conventions.**CallingConventionAnalysisMode**

Bases: Enum

The mode of calling convention analysis.

FAST: Using FactCollector to collect facts, then use facts for calling convention analysis. FASTISH: Using FactCollector with additional introspection to identify behavior of function arguments. VARIABLES: Using variables in VariableManager for calling convention analysis.

**FAST = 'fast'**

**FASTISH = 'fastish'**

**VARIABLES = 'variables'**

**class** angr.analyses.complete_calling_conventions.**CompleteCallingConventionsAnalysis**

Bases: *Analysis*

Implements full-binary calling convention analysis. During the initial analysis of a binary, you may set *recover_variables* to True so that it will perform variable recovery on each function before performing calling convention analysis.

**__init__**(*mode=CallingConventionAnalysisMode.FASTISH*, *recover_variables=False*, *low_priority=False*, *force=False*, *cfg=None*, *analyze_callsites=False*, *skip_signature_matched_functions=False*, *max_function_blocks=None*, *max_function_size=None*, *workers=0*, *cc_callback=None*, *prioritize_func_addrs=None*, *skip_other_funcs=False*, *auto_start=True*, *func_graphs=None*, *target_functions=None*, *flavor=None*)

**Parameters**

- **recover_variables** – Recover variables on each function before performing calling convention analysis.
- **low_priority** – Run in the background - periodically release GIL.
- **force** – Perform calling convention analysis on functions even if they have calling conventions or prototypes already specified (or previously recovered).
- **cfg** (*CFGFast* | *CFGModel* | None) – The control flow graph model, which will be passed to CallingConventionAnalysis.
- **analyze_callsites** (bool) – Consider artifacts at call sites when performing calling convention analysis.
- **skip_signature_matched_functions** (bool) – Do not perform calling convention analysis on functions that match against existing FLIRT signatures.
- **max_function_blocks** (int | None) – Do not perform calling convention analysis on functions with more than the specified number of blocks. Setting it to None disables this check.
- **max_function_size** (int | None) – Do not perform calling convention analysis on functions whose sizes are more than *max_function_size*. Setting it to None disables this check.
- **workers** (int) – Number of multiprocessing workers.
- **flavor** (str | None) – The decompilation flavor whose prototypes the analysis reads and writes (None: the default flavor).
- **mode** (CallingConventionAnalysisMode)

- **cc_callback** (*Callable | None*)
- **prioritize_func_addrs** (*list[int] | set[int] | None*)
- **skip_other_funcs** (*bool*)
- **auto_start** (*bool*)
- **func_graphs** (*dict[int, DiGraph] | None*)
- **target_functions** (*set[int] | None*)

**prototype_libnames:** set[str]

**work**()

**prioritize_functions**(*func_addrs_to_prioritize*)

Prioritize the analysis of specified functions.

**Parameters**
**func_addrs_to_prioritize** (Iterable[int]) – A collection of function addresses to analyze first.

**static function_needs_variable_recovery**(*func*)

Check if running variable recovery on the function is the only way to determine the calling convention of the this function.

We do not need to run variable recovery to determine the calling convention of a function if: - The function is a SimProcedure. - The function is a PLT stub. - The function is a library function and we already know its prototype.

**Parameters**
**func** – The function object.

**Returns**
True if we must run VariableRecovery before we can determine what the calling convention of this function is. False otherwise.

**Return type**
bool

### 10.3.15 angr.analyses.congruency_check

**class** angr.analyses.congruency_check.**CongruencyCheck**

Bases: *Analysis*

This is an analysis to ensure that angr executes things identically with different execution backends (i.e., unicorn vs vex).

**__init__**(*throw=False*)

Initializes a CongruencyCheck analysis.

**Parameters**
**throw** – whether to raise an exception if an incongruency is found.

**set_state_options**(*left_add_options=None*, *left_remove_options=None*, *right_add_options=None*, *right_remove_options=None*)

Checks that the specified state options result in the same states over the next *depth* states.

**set_states**(*left_state*, *right_state*)

Checks that the specified paths stay the same over the next *depth* states.

**set_simgr**(*simgr*)

**run**(*depth=None*)

Checks that the paths in the specified path group stay the same over the next *depth* bytes.

The path group should have a "left" and a "right" stash, each with a single path.

**compare_path_group**(*pg*)

**compare_states**(*sl*, *sr*)

Compares two states for similarity.

**compare_paths**(*pl*, *pr*)

### 10.3.16 angr.analyses.data_dep

**class** angr.analyses.data_dep.**BaseDepNode**

Bases: object

Base class for all nodes in a data-dependency graph

**__init__**(*type_*, *sim_act*)

**Parameters**

- **type_** (*int*)
- **sim_act** (SimActionData)

**value_tuple**()

**Return type**
tuple[BV, int]

**Returns**
A tuple containing the node's value as a BV and as an evaluated integer

**property ast: BV**

**property type: int**

Getter :return: An integer defined in DepNodeTypes, represents the subclass type of this DepNode.

**class** angr.analyses.data_dep.**ConstantDepNode**

Bases: *BaseDepNode*

Used to create a DepNode that will hold a constant, numeric value Uniquely identified by its value

**__init__**(*sim_act*, *value*)

**Parameters**

- **sim_act** (SimActionData)
- **value** (*int*)

**class** angr.analyses.data_dep.**DataDependencyGraphAnalysis**

Bases: *Analysis*

This is a DYNAMIC data dependency graph that utilizes a given SimState to produce a DDG graph that is accurate to the path the program took during execution.

This analysis utilizes the SimActionData objects present in the provided SimState's action history to generate the dependency graph.

__init__(*end_state*, *start_from=None*, *end_at=None*, *block_addrs=None*)

**Parameters**

- **end_state** (*SimState*) – Simulation state used to extract all SimActionData
- **start_from** (int | None) – An address or None, Specifies where to start generation of DDG
- **end_at** (int | None) – An address or None, Specifies where to end generation of DDG
- **block_addrs** (list[int] | None) – List of block addresses that the DDG analysis should be run on

property graph: DiGraph | None

property simplified_graph: DiGraph | None

property sub_graph: DiGraph | None

get_data_dep(*g_node*, *include_tmp_nodes*, *backwards*)

**Return type**
DiGraph | None

**Parameters**

- **g_node** (BaseDepNode)
- **include_tmp_nodes** (*bool*)
- **backwards** (*bool*)

class angr.analyses.data_dep.**DepNodeTypes**

Bases: object

Enumeration of types of BaseDepNode supported by this analysis

Memory = 1

Register = 2

Tmp = 3

Constant = 4

class angr.analyses.data_dep.**MemDepNode**

Bases: *BaseDepNode*

Used to represent SimActions of type MEM

__init__(*sim_act*, *addr*)

**Parameters**

- **sim_act** (SimActionData)
- **addr** (*int*)

property width: int

**classmethod cast_to_mem**(*base_dep_node*)

Casts a BaseDepNode into a MemDepNode

**Parameters**
**base_dep_node** (BaseDepNode)

**class** angr.analyses.data_dep.**RegDepNode**

Bases: *VarDepNode*

Base class for representing SimActions of TYPE reg

**__init__**(*sim_act*, *reg*, *arch_name=''*)

**Parameters**

- **sim_act** (SimActionData)
- **reg** (*int*)
- **arch_name** (*str*)

**property reg_size:** int

**class** angr.analyses.data_dep.**TmpDepNode**

Bases: *VarDepNode*

Used to represent SimActions of type TMP

**__init__**(*sim_act*, *reg*, *arch_name=''*)

**Parameters**

- **sim_act** (SimActionData)
- **reg** (*int*)
- **arch_name** (*str*)

**class** angr.analyses.data_dep.**VarDepNode**

Bases: *BaseDepNode*

Abstract class for representing SimActions of TYPE reg or tmp

**__init__**(*type_*, *sim_act*, *reg*, *arch_name=''*)

**Parameters**

- **type_** (*int*)
- **sim_act** (SimActionData)
- **reg** (*int*)
- **arch_name** (*str*)

**property display_name:** str

## Submodules

| | |
|---|---|
| *data_dependency_analysis* | Defines analysis that will generate a dynamic data-dependency graph |
| *dep_nodes* | |
| *sim_act_location* | |

### angr.analyses.data_dep.data_dependency_analysis

Defines analysis that will generate a dynamic data-dependency graph

**class** angr.analyses.data_dep.data_dependency_analysis.**NodalAnnotation**

Bases: Annotation

Allows a node to be stored as an annotation to a BV in a DefaultMemory instance

**relocatable = False**

Can not be relocated in a simplification

**eliminatable = False**

Can not be eliminated in a simplification

**__init__**(*node*)

**Parameters**
**node** (BaseDepNode)

**class** angr.analyses.data_dep.data_dependency_analysis.**DataDependencyGraphAnalysis**

Bases: *Analysis*

This is a DYNAMIC data dependency graph that utilizes a given SimState to produce a DDG graph that is accurate to the path the program took during execution.

This analysis utilizes the SimActionData objects present in the provided SimState's action history to generate the dependency graph.

**__init__**(*end_state*, *start_from=None*, *end_at=None*, *block_addrs=None*)

**Parameters**

- **end_state** (*SimState*) – Simulation state used to extract all SimActionData
- **start_from** (int | None) – An address or None, Specifies where to start generation of DDG
- **end_at** (int | None) – An address or None, Specifies where to end generation of DDG
- **block_addrs** (list[int] | None) – List of block addresses that the DDG analysis should be run on

**property graph: DiGraph | None**

**property simplified_graph: DiGraph | None**

**property sub_graph: DiGraph | None**

**get_data_dep**(*g_node*, *include_tmp_nodes*, *backwards*)

**Return type**
DiGraph | None

**Parameters**

- **g_node** (BaseDepNode)
- **include_tmp_nodes** (*bool*)
- **backwards** (*bool*)

### angr.analyses.data_dep.dep_nodes

class angr.analyses.data_dep.dep_nodes.**DepNodeTypes**

Bases: object

Enumeration of types of BaseDepNode supported by this analysis

**Memory = 1**

**Register = 2**

**Tmp = 3**

**Constant = 4**

class angr.analyses.data_dep.dep_nodes.**BaseDepNode**

Bases: object

Base class for all nodes in a data-dependency graph

**__init__**(*type_*, *sim_act*)

**Parameters**

- **type_** (*int*)
- **sim_act** (SimActionData)

**action_id:** int

**value:** int | None

**value_tuple**()

**Return type**
tuple[BV, int]

**Returns**
A tuple containing the node's value as a BV and as an evaluated integer

**property ast:** BV

**property type:** int

Getter :return: An integer defined in DepNodeTypes, represents the subclass type of this DepNode.

class angr.analyses.data_dep.dep_nodes.**ConstantDepNode**

Bases: *BaseDepNode*

Used to create a DepNode that will hold a constant, numeric value Uniquely identified by its value

**__init__**(*sim_act*, *value*)

**Parameters**

- **sim_act** (SimActionData)
- **value** (*int*)

class angr.analyses.data_dep.dep_nodes.**MemDepNode**

Bases: *BaseDepNode*

Used to represent SimActions of type MEM

__init__(*sim_act*, *addr*)

**Parameters**

- **sim_act** (SimActionData)
- **addr** (*int*)

property **width**: int

classmethod **cast_to_mem**(*base_dep_node*)

Casts a BaseDepNode into a MemDepNode

**Parameters**

**base_dep_node** (BaseDepNode)

class angr.analyses.data_dep.dep_nodes.**VarDepNode**

Bases: *BaseDepNode*

Abstract class for representing SimActions of TYPE reg or tmp

__init__(*type_*, *sim_act*, *reg*, *arch_name=''*)

**Parameters**

- **type_** (*int*)
- **sim_act** (SimActionData)
- **reg** (*int*)
- **arch_name** (*str*)

property **display_name**: str

class angr.analyses.data_dep.dep_nodes.**TmpDepNode**

Bases: *VarDepNode*

Used to represent SimActions of type TMP

__init__(*sim_act*, *reg*, *arch_name=''*)

**Parameters**

- **sim_act** (SimActionData)
- **reg** (*int*)
- **arch_name** (*str*)

class angr.analyses.data_dep.dep_nodes.**RegDepNode**

Bases: *VarDepNode*

Base class for representing SimActions of TYPE reg

__init__(*sim_act*, *reg*, *arch_name=''*)

**Parameters**

- **sim_act** (SimActionData)
- **reg** (*int*)
- **arch_name** (*str*)

property **reg_size**: int

#### angr.analyses.data_dep.sim_act_location

**class** angr.analyses.data_dep.sim_act_location.**SimActLocation**

Bases: object

Structure-like class used to bundle the instruction address and statement index of a given SimAction in order to uniquely identify a given SimAction

**__init__**(*bbl_addr*, *ins_addr*, *stmt_idx*)

**Parameters**

- **bbl_addr** (*int*)
- **ins_addr** (*int*)
- **stmt_idx** (*int*)

**class** angr.analyses.data_dep.sim_act_location.**ParsedInstruction**

Bases: object

Used by parser to facilitate linking with recent ancestors in an efficient manner

**__init__**(*ins_addr*, *min_stmt_idx*, *max_stmt_idx*)

**Parameters**

- **ins_addr** (*int*)
- **min_stmt_idx** (*int*)
- **max_stmt_idx** (*int*)

### 10.3.17 angr.analyses.datagraph_meta

**exception** angr.analyses.datagraph_meta.**DataGraphError**

Bases: Exception

**class** angr.analyses.datagraph_meta.**DataGraphMeta**

Bases: object

**__init__**()

**get_irsb_at**(*addr*)

**pp**(*imarks=False*)

Pretty print the graph. @imarks determine whether the printed graph represents instructions (coarse grained) for easier navigation, or exact statements.

### 10.3.18 angr.analyses.ddg

**class** angr.analyses.ddg.**AST**

Bases: object

A mini implementation for AST

**__init__**(*op*, **operands*)

class angr.analyses.ddg.**ProgramVariable**

Bases: object

Describes a variable in the program at a specific location.

**Variables**

- **variable** (SimVariable) – The variable.
- **location** (CodeLocation) – Location of the variable.

**__init__**(*variable*, *location*, *initial=False*, *arch=None*)

**property short_repr**

class angr.analyses.ddg.**DDGJob**

Bases: object

**__init__**(*cfg_node*, *call_depth*)

class angr.analyses.ddg.**LiveDefinitions**

Bases: object

A collection of live definitions with some handy interfaces for definition killing and lookups.

**__init__**()

Constructor.

**branch**()

Create a branch of the current live definition collection.

**Returns**
A new LiveDefinition instance.

**Return type**
*angr.analyses.ddg.LiveDefinitions*

**copy**()

Make a hard copy of *self*.

**Returns**
A new LiveDefinition instance.

**Return type**
*angr.analyses.ddg.LiveDefinitions*

**add_def**(*variable*, *location*, *size_threshold=32*)

Add a new definition of variable.

**Parameters**

- **variable** (SimVariable) – The variable being defined.
- **location** (CodeLocation) – Location of the variable being defined.
- **size_threshold** (*int*) – The maximum bytes to consider for the variable.

**Returns**
True if the definition was new, False otherwise

**Return type**
bool

**add_defs**(*variable*, *locations*, *size_threshold=32*)

Add a collection of new definitions of a variable.

**Parameters**

- **variable** (SimVariable) – The variable being defined.
- **locations** (*iterable*) – A collection of locations where the variable was defined.
- **size_threshold** (*int*) – The maximum bytes to consider for the variable.

**Returns**
True if any of the definition was new, False otherwise

**Return type**
bool

**kill_def**(*variable*, *location*, *size_threshold=32*)

Add a new definition for variable and kill all previous definitions.

**Parameters**

- **variable** (SimVariable) – The variable to kill.
- **location** (CodeLocation) – The location where this variable is defined.
- **size_threshold** (*int*) – The maximum bytes to consider for the variable.

**Returns**
None

**lookup_defs**(*variable*, *size_threshold=32*)

Find all definitions of the variable.

**Parameters**

- **variable** (SimVariable) – The variable to lookup for.
- **size_threshold** (*int*) – The maximum bytes to consider for the variable. For example, if the variable is 100 byte long, only the first *size_threshold* bytes are considered.

**Returns**
A set of code locations where the variable is defined.

**Return type**
set

**items**()

An iterator that returns all live definitions.

**Returns**
The iterator.

**Return type**
iter

**itervariables**()

An iterator that returns all live variables.

**Returns**
The iterator.

**Return type**
iter

class angr.analyses.ddg.**DDGViewItem**

Bases: object

**__init__**(*ddg*, *variable*, *simplified=False*)

**property depends_on**

**property dependents**

class angr.analyses.ddg.**DDGViewInstruction**

Bases: object

**__init__**(*cfg*, *ddg*, *insn_addr*, *simplified=False*)

**property definitions: list[*DDGViewItem*]**

Get all definitions located at the current instruction address.

**Returns**
A list of ProgramVariable instances.

class angr.analyses.ddg.**DDGView**

Bases: object

A view of the data dependence graph.

**__init__**(*cfg*, *ddg*, *simplified=False*)

class angr.analyses.ddg.**DDG**

Bases: *Analysis*

This is a fast data dependence graph directly generated from our CFG analysis result. The only reason for its existence is the speed. There is zero guarantee for being sound or accurate. You are supposed to use it only when you want to track the simplest data dependence, and you do not care about soundness or accuracy.

For a better data dependence graph, please consider performing a better static analysis first (like Value-set Analysis), and then construct a dependence graph on top of the analysis result (for example, the VFG in angr).

The DDG is based on a CFG, which should ideally be a CFGEmulated generated with the following options:

- keep_state=True to keep all input states
- state_add_options=angr.options.refs to store memory, register, and temporary value accesses

You may want to consider a high value for context_sensitivity_level as well when generating the CFG.

Also note that since we are using states from CFG, any improvement in analysis performed on CFG (like a points-to analysis) will directly benefit the DDG.

**__init__**(*cfg*, *start=None*, *call_depth=None*, *block_addrs=None*)

**Parameters**

- **cfg** – Control flow graph. Please make sure each node has an associated *state* with it, e.g. by passing the keep_state=True and state_add_options=angr.options.refs arguments to CFGEmulated.
- **start** – An address, Specifies where we start the generation of this data dependence graph.
- **call_depth** – None or integers. A non-negative integer specifies how deep we would like to track in the call tree. None disables call_depth limit.
- **block_addrs** (*iterable or None*) – A collection of block addresses that the DDG analysis should be performed on.

property graph

A networkx DiGraph instance representing the dependence relations between statements. :rtype: networkx.DiGraph

**Type**
returns

property data_graph

Get the data dependence graph.

**Returns**
A networkx DiGraph instance representing data dependence.

**Return type**
networkx.DiGraph

property simplified_data_graph

return:

property ast_graph

pp()

Pretty printing.

dbg_repr()

Representation for debugging.

get_predecessors(*code_location*)

Returns all predecessors of the code location.

**Parameters**
**code_location** – A CodeLocation instance.

**Returns**
A list of all predecessors.

function_dependency_graph(*func*)

Get a dependency graph for the function *func*.

**Parameters**
**func** – The Function object in CFG.function_manager.

**Returns**
A networkx.DiGraph instance.

data_sub_graph(*pv*, *simplified=True*, *killing_edges=False*, *excluding_types=None*)

Get a subgraph from the data graph or the simplified data graph that starts from node pv.

**Parameters**

- **pv** (*ProgramVariable*) – The starting point of the subgraph.
- **simplified** (*bool*) – When True, the simplified data graph is used, otherwise the data graph is used.
- **killing_edges** (*bool*) – Are killing edges included or not.
- **excluding_types** (*iterable*) – Excluding edges whose types are among those excluded types.

**Returns**
A subgraph.

**Return type**
networkx.MultiDiGraph

**find_definitions**(*variable*, *location=None*, *simplified_graph=True*)

Find all definitions of the given variable.

**Parameters**

- **variable** (SimVariable)
- **simplified_graph** (*bool*) – True if you just want to search in the simplified graph instead of the normal graph. Usually the simplified graph suffices for finding definitions of register or memory variables.

**Returns**
A collection of all variable definitions to the specific variable.

**Return type**
list

**find_consumers**(*var_def*, *simplified_graph=True*)

Find all consumers to the specified variable definition.

**Parameters**

- **var_def** (ProgramVariable) – The variable definition.
- **simplified_graph** (*bool*) – True if we want to search in the simplified graph, False otherwise.

**Returns**
A collection of all consumers to the specified variable definition.

**Return type**
list

**find_killers**(*var_def*, *simplified_graph=True*)

Find all killers to the specified variable definition.

**Parameters**

- **var_def** (ProgramVariable) – The variable definition.
- **simplified_graph** (*bool*) – True if we want to search in the simplified graph, False otherwise.

**Returns**
A collection of all killers to the specified variable definition.

**Return type**
list

**find_sources**(*var_def*, *simplified_graph=True*)

Find all sources to the specified variable definition.

**Parameters**

- **var_def** (ProgramVariable) – The variable definition.
- **simplified_graph** (*bool*) – True if we want to search in the simplified graph, False otherwise.

**Returns**
A collection of all sources to the specified variable definition.

**Return type**
list

### 10.3.19 angr.analyses.decompiler

**class** angr.analyses.decompiler.**AILSimplifier**

Bases: *Analysis*

Perform function-level simplifications.

**__init__**(*func*, *func_graph*, *ail_manager*, *remove_dead_memdefs=False*, *stackarg_offset_manager=None*, *unify_variables=False*, *gp=None*, *narrow_expressions=False*, *fold_expressions=True*, *only_consts=False*, *fold_callexprs_into_conditions=False*, *use_callee_saved_regs_at_return=True*, *rewrite_ccalls=True*, *rename_ccalls=True*, *rewrite_dirty=True*, *removed_vvar_ids=None*, *arg_vvars=None*, *avoid_vvar_ids=None*, *secondary_stackvars=None*, *remove_dead_assignments=True*)

**Parameters**

- **func** (Function)
- **func_graph** (*networkx.DiGraph[Block]*)
- **ail_manager** (*Manager*)
- **stackarg_offset_manager** (StackArgOffsetManager | *None*)
- **gp** (*int* | *None*)
- **removed_vvar_ids** (*set[int]* | *None*)
- **arg_vvars** (*dict[int, tuple[VirtualVariable, SimVariable]]* | *None*)
- **avoid_vvar_ids** (*set[int]* | *None*)
- **secondary_stackvars** (*set[int]* | *None*)
- **remove_dead_assignments** (*bool* | *None*)

**class** angr.analyses.decompiler.**BaseStructuredCodeGenerator**

Bases: object

**__init__**(*flavor=None*, *notes=None*, *expr_comments=None*, *stmt_comments=None*, *const_formats=None*)

**static adjust_mapping_positions**(*offset*, *pos_to_node*, *pos_to_addr*, *addr_to_pos*)

Adjust positions in the mappings to account for the notes that are prepended to the text.

**Parameters**

- **offset** (int) – The length of the notes to prepend.
- **pos_to_node** (*PositionMapping*) – The position to node mapping.
- **pos_to_addr** (*PositionMapping*) – The position to address mapping.
- **addr_to_pos** (*InstructionMapping*) – The address to position mapping.

**Return type**
tuple[*PositionMapping*, *PositionMapping*, *InstructionMapping*]

**Returns**
Adjusted mappings.

**reapply_options**(*options*)

**regenerate_text**()

**Return type**
None

**reload_variable_types**()

**Return type**
None

**next_ident**(*key*)

**Return type**
str

**Parameters**
**key** (*str*)

**reset_ident_counters**()

**Return type**
None

**next_node_idx**()

**Return type**
int

**class** angr.analyses.decompiler.**BlockSimplifier**

Bases: object

Simplify an AIL block.

Deliberately not an Analysis: it is instantiated once per block, hundreds of times per decompilation, so it skips the analysis-factory ceremony. Instantiate it directly with the project as the first argument; exceptions always propagate.

**__init__**(*project*, *block*, *ail_manager*, *func_addr=None*, *stack_pointer_tracker=None*, *peephole_optimizations=None*, *preserve_vvar_ids=None*, *type_hints=None*, *cached_propagator=None*, *peephole_bundle=None*, *graph_defs=None*)

**Parameters**

- **block** (Block | None) – The AIL block to simplify. Setting it to None to skip calling self._analyze(), which is useful in test cases.
- **peephole_bundle** (*PeepholeOptimizationBundle* | None) – A pre-built PeepholeOptimizationBundle to reuse. Its construction parameters must match this BlockSimplifier's; callers that simplify many blocks should build one bundle and pass it to every BlockSimplifier they create.
- **graph_defs** (*GraphVVarDefs* | None) – Unique vvar definitions of the graph the block belongs to, for peephole optimizations that see through definitions made in other blocks.
- **project** (Project)
- **ail_manager** (*Manager*)
- **func_addr** (*int | None*)
- **peephole_optimizations** (*Iterable[*type*[*PeepholeOptimizationStmtBase | PeepholeOptimizationExprBase | PeepholeOptimizationMultiStmtBase*]] | None*)

- **preserve_vvar_ids** (*set[int] | None*)
- **type_hints** (*list[tuple[atoms.VirtualVariable | atoms.MemoryLocation, str]] | None*)

**static replace_and_build**(*block*, *replacements*, *ail_manager*, *replace_assignment_dsts=False*, *replace_loads=False*, *gp=None*, *replace_registers=True*, *max_expr_depth=13*, *max_stmt_size=20000*)

**Return type**
tuple[bool, Block]

**Parameters**

- **block** (Block)
- **replacements** (*Mapping[AILCodeLocation, Mapping[Expression, Expression]]*)
- **ail_manager** (*Manager*)
- **replace_assignment_dsts** (*bool*)
- **replace_loads** (*bool*)
- **gp** (*int | None*)
- **replace_registers** (*bool*)
- **max_expr_depth** (*int | None*)
- **max_stmt_size** (*int*)

**class** angr.analyses.decompiler.**CStructuredCodeGenerator**

Bases: *BaseStructuredCodeGenerator*, *Analysis*, *Serializable*

**__init__**(*func*, *sequence*, *indent=0*, *cfg=None*, *func_args=None*, *binop_depth_cutoff=16*, *show_casts=True*, *braces_on_own_lines=True*, *use_compound_assignments=True*, *show_local_types=True*, *comment_gotos=False*, *cstyle_null_cmp=True*, *flavor=None*, *stmt_comments=None*, *expr_comments=None*, *show_externs=True*, *externs=None*, *const_formats=None*, *show_demangled_name=True*, *show_disambiguated_name=True*, *ail_graph=None*, *simplify_else_scope=True*, *cstyle_ifs=True*, *omit_func_header=False*, *display_block_addrs=False*, *display_vvar_ids=False*, *min_data_addr=4194304*, *notes=None*, *display_notes=True*, *max_str_len=None*, *prettify_thiscall=False*, *cstyle_void_param=True*, *indent_size=4*, *variable_map=None*, *stl_accessor_calls=False*)

**Parameters**

- **func** (Function)
- **func_args** (*list[SimVariable] | None*)
- **binop_depth_cutoff** (*int*)
- **min_data_addr** (*int*)
- **display_notes** (*bool*)
- **max_str_len** (*int | None*)
- **prettify_thiscall** (*bool*)
- **cstyle_void_param** (*bool*)
- **indent_size** (*int*)

- **variable_map** (VariableMap | *None*)
- **stl_accessor_calls** (*bool*)

**reapply_options**(*options*)

**cleanup**()

Remove existing rendering results.

**regenerate_text**()

Re-render text and re-generate all sorts of mapping information.

**Return type**
None

**render_text**(*cfunc*)

**Return type**

**Parameters**
**cfunc** (CFunction)

**render_notes**()

Render decompilation notes.

**Return type**
str

**Returns**
A string containing all notes.

**reload_variable_types**()

**Return type**
None

**default_simtype_from_bits**(*n*, *signed=True*)

**Return type**
*SimType*

**Parameters**

- **n** (*int*)
- **signed** (*bool*)

**variables_unify**(*v1*, *v2*)

**Return type**
bool

**Parameters**

- **v1** (VirtualVariable)
- **v2** (VirtualVariable)

**ERRNO_LOCATION_FUNCS = frozenset({'__errno', '__errno_location', '__error', '_errno'})**

The libc functions that return `&errno`. `errno` is a macro that dereferences one of them, so it never survives into a binary as a symbol; what reaches decompilation is `*(__errno_location())`, which is both correct and unreadable.

class angr.analyses.decompiler.**CallSiteMaker**

Bases: object

Add calling convention, declaration, and args to a call site.

**__init__**(*project*, *block*, ***, *ail_manager*, *reaching_definitions=None*, *stack_pointer_tracker=None*, *x87_call_ftop=None*, *flavor=Flavors.DEFAULT_FLAVOR*)

**Parameters**

- **project** (Project)
- **ail_manager** (*Manager*)
- **reaching_definitions** (SRDAModel | *None*)
- **x87_call_ftop** (*dict[int, int]* | *None*)
- **flavor** (*str*)

class angr.analyses.decompiler.**Clinic**

Bases: *Analysis*, *Serializable*

A Clinic deals with AILments: it lifts a function to AIL and runs the decompiler's simplification pipeline on it.

AIL graphs exposed after a DECOMPILE-mode run:

- `cc_graph`: the graph at the end of Clinic's own simplification, frozen as a copy before region identification. Serialized; available on both live and cached-and-reloaded clinics.
- `graph`: `cc_graph` further transformed by the decompiler's graph-simplification passes, region identification, and region-simplification passes — the final graph. Serialized; available on both live and cached-and-reloaded clinics.
- `unoptimized_graph`: a copy taken before the first structure-altering optimization pass; use it for an exact instruction-to-AIL mapping. Only built (and serialized) with `Decompiler(save_unoptimized_graph=True)`; otherwise it is None on both live and cached-and-reloaded clinics.
- `_ail_graph` / `_init_ail_graph`: pipeline internals; never serialized.

**CROSS_INSN_OPT_MIN_BLOCK_SIZE = 99**

lift a block with cross-insn-opt only when it contains at least this many bytes

**CROSS_INSN_OPT_MIN_LARGE_BLOCK_COUNT = 400**

…and only in functions with at least this many such blocks

**CROSS_INSN_OPT_MAX_BINOP_COUNT = 3**

…and it has fewer BinOps than this in total

**CROSS_INSN_OPT_MIN_STRIDE_REPEATS = 30**

…and only when the block contains this many consecutive repeating byte strides

**CROSS_INSN_OPT_MAX_STRIDE = 4**

longest byte stride when looking for repeating patterns

__init__(*func*, *remove_dead_memdefs=False*, *exception_edges=False*, *sp_tracker_track_memory=True*, *fold_expressions=True*, *fold_callexprs_into_conditions=False*, *insert_labels=True*, *optimization_passes=None*, *cfg=None*, *peephole_optimizations=None*, *must_struct=None*, *reset_variable_names=False*, *rewrite_ites_to_diamonds=True*, *rewrite_ites_to_diamond_max_cases=15*, *cache=None*, *mode=ClinicMode.DECOMPILE*, *sp_shift=0*, *inline_functions=None*, *inlined_counts=None*, *inlining_parents=None*, *vvar_id_start=0*, *optimization_scratch=None*, *desired_variables=None*, *force_loop_single_exit=True*, *refine_loops_with_single_successor=False*, *expose_loop_head_backedges=False*, *force_single_loop_entry=False*, *typehoon_cls=<class 'angr.analyses.typehoon.typehoon.Typehoon'>*, *max_ail_statements=1000000*, *max_type_constraints=100000*, *type_constraint_set_degradation_threshold=150*, *ail_graph=None*, *arg_vvars=None*, *start_stage=ClinicStage.INITIALIZATION*, *end_stage=None*, *skip_stages=()*, *notes=None*, *static_vvars=None*, *static_buffers=None*, *flatten_args=False*, *constrain_callee_prototypes=False*, *semvar_naming=True*, *flavor=Flavors.DEFAULT_FLAVOR*, *variable_map=None*, *save_unoptimized_graph=False*, *known_patterns=None*, *recognize_known_patterns=True*)

**Parameters**

- **func** (Function)
- **peephole_optimizations** (*Iterable[type[PeepholeOptimizationStmtBase | PeepholeOptimizationExprBase]] | None*)
- **must_struct** (*set[str] | None*)
- **rewrite_ites_to_diamond_max_cases** (*int*)
- **cache** (DecompilationCache | *None*)
- **mode** (ClinicMode)
- **sp_shift** (*int*)
- **inline_functions** (*set[Function] | None*)
- **inlined_counts** (*dict[int, int] | None*)
- **inlining_parents** (*set[int] | None*)
- **vvar_id_start** (*int*)
- **optimization_scratch** (*dict[str, Any] | None*)
- **desired_variables** (*set[str] | None*)
- **force_loop_single_exit** (*bool*)
- **refine_loops_with_single_successor** (*bool*)
- **expose_loop_head_backedges** (*bool*)
- **force_single_loop_entry** (*bool*)
- **max_ail_statements** (*int*)
- **max_type_constraints** (*int*)
- **type_constraint_set_degradation_threshold** (*int*)
- **ail_graph** (*networkx.DiGraph | None*)
- **arg_vvars** (*dict[int, tuple[ailment.Expr.VirtualVariable, SimVariable]] | None*)
- **start_stage** (ClinicStage | *None*)

- **end_stage** (*ClinicStage | None*)
- **skip_stages** (*tuple[ClinicStage, ...]*)
- **notes** (*dict[str, DecompilationNote] | None*)
- **static_vvars** (*dict | None*)
- **static_buffers** (*dict | None*)
- **constrain_callee_prototypes** (*bool*)
- **semvar_naming** (*bool*)
- **flavor** (*str*)
- **variable_map** (*VariableMap | None*)
- **save_unoptimized_graph** (*bool*)
- **known_patterns** (*str | tuple[str, ...] | None*)
- **recognize_known_patterns** (*bool*)

**block**(*addr*, *size*)

Get the converted block at the given specific address with the given size.

**Parameters**

- **addr** (*int*)
- **size** (*int*)

**Returns**

**dbg_repr**()

**Returns**

**calculate_stack_depth**()

**copy_graph**(*graph=None*)

**Return type**
DiGraph

**MAX_CALLEE_CLEANUP_SUBSET_CANDIDATES = 4**

**block_lifted_with_cross_insn_opt**(*block_addr*, *block_size*)

**Return type**
bool

**Parameters**

- **block_addr** (*int*)
- **block_size** (*int*)

**static repeating_stride_run**(*data*, *max_stride*)

The longest run of consecutive repetitions of up to `max_stride` bytes in `data`.

**Return type**
int

**Parameters**

- **data** (bytes)

- **max_stride** (*int*)

**static binop_count**(*block*)

The number of binary operations across all statements of `block`.

**Return type**
int

**Parameters**
**block** (*Block*)

**parse_variable_addr**(*addr*)

**Return type**
tuple[Any, Any]

**Parameters**
**addr** (Expression)

**new_block_addr**()

Return a block address that does not conflict with any existing blocks.

**Return type**
int

**Returns**
The block address.

**static remove_empty_nodes**(*graph*)

**Return type**
DiGraph

**Parameters**
**graph** (*DiGraph*)

**constrain_callee_prototypes**()

Constrain the types of callee function arguments based on facts that are observed at call sites. Note that this function will change the prototypes of (callee) functions in the knowledge base, which means it may affect the decompilation output of the current function if it is decompiled again.

**resolve_peephole_optimizations**()

Retry resolving peephole-optimization names that were unresolvable at parse time (their defining module may have been imported since). Resolved classes move into `peephole_optimizations`; names that still do not resolve stay in `unresolvable_peephole_optimizations`.

**Return type**
None

**classmethod parse_from_cmessage**(*cmsg*, *, *project=None*, *kb=None*, *function=None*, *cfg=None*, ***kwargs*)

Bypasses `Clinic.__init__()` (which runs the analysis) and reconstructs the instance directly. Runtime back-references — project / kb / function / _cfg — come from kwargs.

Only the state consumed by the decompiler's cache-reuse path and by post-decompilation consumers (cc_graph, graph, optionally unoptimized_graph) is serialized; regenerable and runtime-only state is restored to its default here. If `function` is None and `kb` is provided, the function is resolved by address from the cmessage.

class angr.analyses.decompiler.**ClinicMode**

Bases: Enum

Analysis mode for Clinic.

**DECOMPILE = 1**

**COLLECT_DATA_REFS = 2**

class angr.analyses.decompiler.**DecompilationCache**

Bases: *Serializable*

Caches key data structures that can be used later for refining decompilation results, such as retyping variables.

**__init__**(*addr*)

**parameters:** dict[str, Any]

**version:** str

**timestamp:** int

**addr**

**cfg:** *CFGModel* | None

**type_constraints:** dict[*TypeVariable*, set[*TypeConstraint*]]

**arg_vvars:** dict

**func_typevar:** *TypeVariable* | None

**var_to_typevar:** dict

**stackvar_max_sizes:** dict

**stack_offset_typevars:** dict

**codegen:** *BaseStructuredCodeGenerator* | None

**clinic:** *Clinic* | None

**variable_map:** *VariableMap* | None

**ite_exprs:** set[tuple[int, *Expression*]]

**binop_operators:** dict[*OpDescriptor*, str]

**errors:** list[str]

**function_summary:** str | None

**notes:** dict[str, *DecompilationNote*]

**max_tv_id:** int

**go_sigs_version:** int | None

**go_sigs_deps:** dict[str, int] | None

**property local_types**

**classmethod parse_from_cmessage**(*cmsg*, ***, *project=None*, *kb=None*, *function=None*, *cfg=None*, ***_*)

Parse a DecompilationCache from a cmessage. Runtime back-references (project, kb, function, cfg) are passed through to the embedded Clinic / codegen parsers so the parsed cache is functional for cache-hit validity checks. Decompilation variables live on kb.dec_variables.

**class** angr.analyses.decompiler.**Decompiler**

Bases: *Analysis*

The decompiler analysis.

Run this on a Function object for which a normalized CFG has been constructed. The fully processed output can be found in result.codegen.text

AIL graphs exposed on the result (both on a fresh run and on a cache hit, including caches reloaded from angrdb or the runtime-db spill):

- `ail_graph` (= `clinic.cc_graph`): the simplified graph before region identification.
- `clinic.graph`: the final graph after region identification and region simplification.
- `unoptimized_ail_graph` (= `clinic.unoptimized_graph`): a snapshot before the first structure-altering optimization pass; use it for an exact instruction-to-AIL mapping. Only built when `save_unoptimized_graph=True` is passed; otherwise this attribute is None on both fresh runs and cache hits.

Complexity guard: pathologically large functions (e.g. packer filler that linear disassembly turns into thousands of blocks) can keep the pipeline busy indefinitely, so two size limits are checked before the expensive work starts. `max_function_blocks` (default 50000, `DEFAULT_MAX_FUNCTION_BLOCKS`) bounds the number of CFG basic blocks and is checked before any AIL is built; `max_ail_statements` (default 1000000, `DEFAULT_MAX_AIL_STATEMENTS`) bounds the number of AIL statements and is checked right after the AIL graph is built. Both are ~10x the largest function in angr's test binary corpus. Either limit can be changed through the decompilation option of the same name, and setting one to 0 disables it. When a limit is exceeded, decompilation stops with an `AngrDecompilationComplexityError` naming the limit and the actual size: with `fail_fast=True` it is raised, otherwise it is recorded in `self.errors` (and in `kb.decompilations[...].errors`) and exposed as `complexity_error`, and `codegen` stays None.

The optimization passes come from `preset` (a name or a DecompilationPreset), or from an explicit `optimization_passes` list when no preset is given. `disable_opts` drops individual passes from the preset's list, which is how a caller asks for "this preset, minus that one pass" without restating it.

**__init__**(*func*, *cfg=None*, *options=None*, *preset=None*, *optimization_passes=None*, *disable_opts=None*, *sp_tracker_track_memory=True*, *peephole_optimizations=None*, *vars_must_struct=None*, *flavor=Flavors.DEFAULT_FLAVOR*, *expr_comments=None*, *stmt_comments=None*, *ite_exprs=None*, *binop_operators=None*, *decompile=True*, *regen_clinic=False*, *inline_functions=None*, *desired_variables=None*, *update_memory_data=True*, *want_full_graph=False*, *generate_code=True*, *use_cache=True*, *update_cache=True*, *expr_collapse_depth=16*, *clinic_graph=None*, *clinic_arg_vvars=None*, *clinic_start_stage=None*, *clinic_end_stage=None*, *clinic_skip_stages=()*, *static_vvars=None*, *static_buffers=None*, *codegen_cls=<class 'angr.analyses.decompiler.structured_codegen.c.CStructuredCodeGenerator'>*, *save_unoptimized_graph=False*, *go_sigs_rerun=True*)

**Parameters**

- **func** (Function | *str* | *int*)
- **cfg** (CFGFast | CFGModel | *None*)
- **preset** (*str* | DecompilationPreset | *None*)
- **peephole_optimizations** (*_PEEPHOLE_OPTIMIZATIONS_TYPE*)

- **vars_must_struct** (*set[str] | None*)
- **flavor** (*str*)
- **update_memory_data** (*bool*)
- **want_full_graph** (*bool*)
- **generate_code** (*bool*)
- **use_cache** (*bool*)
- **update_cache** (*bool*)
- **expr_collapse_depth** (*int*)
- **static_vvars** (*dict | None*)
- **static_buffers** (*dict | None*)
- **save_unoptimized_graph** (*bool*)
- **go_sigs_rerun** (*bool*)

**property complexity_error:** *AngrDecompilationComplexityError* | None

The complexity-limit violation that aborted this decompilation, or None if no limit was exceeded. Inspect `limit_name`, `limit`, and `actual` on it to decide whether to raise the limit or skip the function.

**reflow_variable_types**(*cache*)

Re-run type inference on an existing variable recovery result, then rerun codegen to generate new results.

**Returns**

**Parameters**
**cache** (DecompilationCache)

**find_data_references_and_update_memory_data**(*seq_node*)

**Parameters**
**seq_node** (SequenceNode)

**transform_graph_from_ssa**(*ail_graph*)

Translate an SSA AIL graph out of SSA form. This is useful for producing a non-SSA AIL graph for displaying in angr management.

**Parameters**
**ail_graph** (DiGraph) – The AIL graph to transform out of SSA form.

**Return type**
DiGraph

**Returns**
The translated AIL graph.

**transform_seqnode_from_ssa**(*seq_node*)

**Return type**
*SequenceNode*

**Parameters**
**seq_node** (SequenceNode)

**llm_refine**()

Use the configured LLM to suggest improved variable names, function names, and variable types. Returns True if any changes were made.

**Return type**
bool

**llm_suggest_variable_names**(*llm_client=None*, *code_text=None*, *raise_exc=False*)

Ask the LLM to suggest better variable names for the decompiled code. Returns True if any variables were renamed.

**Parameters**

- **raise_exc** (bool) – If True, exceptions from the LLM call are propagated to the caller. If False (default), exceptions are caught and the method returns False.
- **code_text** (*str | None*)

**Return type**
bool

**llm_suggest_function_name**(*llm_client=None*, *code_text=None*, *raise_exc=False*)

Ask the LLM to suggest a better function name. Only suggests rename for auto-generated names (starting with sub_ or fcn.). Returns True if the function was renamed.

**Parameters**

- **raise_exc** (bool) – If True, exceptions from the LLM call are propagated to the caller.
- **code_text** (*str | None*)

**Return type**
bool

**llm_suggest_variable_types**(*llm_client=None*, *code_text=None*, *raise_exc=False*)

Ask the LLM to suggest better C types for variables. Returns True if any variable types were changed.

**Parameters**

- **raise_exc** (bool) – If True, exceptions from the LLM call are propagated to the caller.
- **code_text** (*str | None*)

**Return type**
bool

**llm_summarize_function**(*llm_client=None*, *code_text=None*, *raise_exc=False*)

Ask the LLM to produce a natural-language summary of what the decompiled function does. The summary is stored in the DecompilationCache and returned.

Returns the summary string, or None if summarization failed.

**Parameters**

- **raise_exc** (bool) – If True, exceptions from the LLM call are propagated to the caller.
- **code_text** (*str | None*)

**Return type**
str | None

**static options_to_params**(*options*)

Convert decompilation options to a dict of params.

**Parameters**
**options** (list[tuple[*DecompilationOption*, Any]]) – The decompilation options.

**Return type**
dict[str, Any]

**Returns**
A dict of keyword arguments.

class angr.analyses.decompiler.**GraphDephication**

Bases: *DephicationBase*

GraphDephication removes phi expressions from an AIL graph, essentially transforms a partial-SSA form of AIL graph to a normal AIL graph.

**__init__**(*func*, *ail_graph*, *vvar_to_vvar_mapping=None*, *rewrite=False*, *variable_map=None*)

**Parameters**
- **func** (*Function* | str) – The subject of the analysis: a function, or a single basic block
- **ail_graph** – The AIL graph to transform.
- **vvar_to_vvar_mapping** (*dict[int, int] | None*)
- **rewrite** (*bool*)
- **variable_map** (VariableMap | *None*)

class angr.analyses.decompiler.**ImportSourceCode**

Bases: *BaseStructuredCodeGenerator*, *Analysis*

**__init__**(*function*, *flavor='source'*, *source_root=None*, *encoding='utf-8'*)

**regenerate_text**()

class angr.analyses.decompiler.**KnownPattern**

Bases: object

A known code idiom, described declaratively.

**Variables**
- **name** (str) – Identifier, e.g. "std_string_length".
- **display_name** (str) – Human-readable name, e.g. "std::string::length".
- **call_name** (str) – Target name of the synthesized Call.
- **pattern** (*PatternExpr* | *PatternStmt* | *PGraphPat*) – The structural pattern to match.
- **params** (tuple[*PatternParam*, ...]) – Ordered parameters; their captures become the call arguments, in order.
- **returnty** (str | *CppRef* | None) – Return type of the synthesized call.
- **returnty_factory** (Callable[[Arch, dict[str, int]], *SimType* | None] | None) – Optional callable building a call-site-specific return type from the values of the constant extra_args captures (e.g. CONTAINING_RECORD returns a pointer to a record whose layout depends on the matched field offset). Falls back to returnty when it returns None or when the constant values are unavailable.
- **extra_args** (tuple[str, ...]) – Names of (typically constant) captures appended to the call arguments after params.
- **arches** (tuple[str, ...] | None) – Allowed archinfo.Arch.name values; None = any.

- **platforms** (tuple[str, ...] | None) – Allowed OS names (`project.simos.name`, lowercased); None = any.
- **where** (Callable[[dict[str, *Expression*]], bool] | None) – Optional cross-capture predicate evaluated on the bindings after a structural match.
- **collapse_capture** (str | None) – Optional capture name identifying the idiom that a match belongs to: within one function, matches binding it to the same virtual variable all describe *one* source-level idiom, and only the one with the largest `collapse_max_capture` constant is kept. The compiler folds CONTAINING_RECORD's subtraction into every field displacement, so one source idiom otherwise emits a call per field, each naming a different (and mostly wrong) record base.
- **collapse_max_capture** (str | None) – Capture whose constant value orders the collapsing; required when `collapse_capture` is set.
- **binary_guard** (Callable[[*Project*], bool] | None) – Optional predicate on the Project; the pattern is only used when it returns True (e.g. require C++ evidence for STL patterns to avoid false positives on plain C binaries).
- **default_enabled** (bool) – Whether the pattern is used when the caller does not explicitly select patterns. Generic patterns prone to false positives should set this False.

**name:** str

**display_name:** str

**call_name:** str

**pattern:** *PatternExpr* | *PatternStmt* | *PGraphPat*

**params:** tuple[*PatternParam*, ...]

**returnty:** str | *CppRef* | None = None

**returnty_factory:** Callable[[Arch, dict[str, int]], *SimType* | None] | None = None

**extra_args:** tuple[str, ...] = ()

**arches:** tuple[str, ...] | None = None

**platforms:** tuple[str, ...] | None = None

**where:** Callable[[dict[str, *Expression*]], bool] | None = None

**collapse_capture:** str | None = None

**collapse_max_capture:** str | None = None

**binary_guard:** Callable[[*Project*], bool] | None = None

**default_enabled:** bool = True

**suppressed_by:** tuple[str, str, str] | None = None

Drop a match of this pattern when a pattern whose name matches the regex matched on the same object: `(name regex, my capture, their capture)`. The two captures must bind `.likes()`-equal expressions. This is how a generic accessor yields to a specific one on the same base: a bare `Load(s + 8)` is std::string::length on a string and _M_finish on a vector, and the vector's other fields say which. Judged against every match of the suppressing family, selected or not, so it cannot interact with largest-match selection.

**claims_only**: bool = False

Match only to claim a base for `suppressed_by` purposes; never outlined, never rewritten, never reported. For shapes that identify an object beyond doubt but are not worth naming: a vector's capacity check says "this is a vector" and nothing a reader wants a call for.

**pure_calls**: frozenset[str] = frozenset({})

Callees this pattern reads through *PCallResult* whose only effect is their result: once the pattern has consumed that result and nothing else does, the call goes too. Naming a callee in a pattern is already a claim about what it computes; this is the claim that it computes nothing else. `__ctype_b_loc` returns a table pointer, and a bare `__ctype_b_loc();` left behind after `isspace(c)` is noise.

**applicable**(*arch_name*, *platform*)

**Return type**
bool

**Parameters**

- **arch_name** (*str*)
- **platform** (*str | None*)

**const_args_of_call**(*call*)

Recover the `extra_args` constant values from a synthesized call's trailing arguments. Returns None when the call does not carry them.

**Return type**
dict[str, int] | None

**Parameters**
**call** (Call)

**prototype**(*arch*, *const_args=None*)

Build the synthesized call's prototype. `const_args` (the values of the constant `extra_args` captures, see `const_args_of_call()`) enables call-site-specific return types via `returnty_factory`. Returns None if any declared type fails to resolve.

**Return type**
*SimTypeFunction* | None

**Parameters**

- **arch** (*archinfo.Arch*)
- **const_args** (*dict[str, int] | None*)

**__init__**(*name*, *display_name*, *call_name*, *pattern*, *params*, *returnty=None*, *returnty_factory=None*, *extra_args=()*, *arches=None*, *platforms=None*, *where=None*, *collapse_capture=None*, *collapse_max_capture=None*, *binary_guard=None*, *default_enabled=True*, *suppressed_by=None*, *claims_only=False*, *pure_calls=frozenset({})*)

**Parameters**

- **name** (*str*)
- **display_name** (*str*)
- **call_name** (*str*)
- **pattern** (PatternExpr | PatternStmt | PGraphPat)
- **params** (*tuple[PatternParam, ...]*)

- **returnty** (TypeRef | *None*)
- **returnty_factory** (Callable[[archinfo.Arch, dict[str, int]], SimType | None] | None)
- **extra_args** (*tuple[str, ...]*)
- **arches** (*tuple[str, ...]* | *None*)
- **platforms** (*tuple[str, ...]* | *None*)
- **where** (Callable[[dict[str, Expression]], bool] | *None*)
- **collapse_capture** (*str* | *None*)
- **collapse_max_capture** (*str* | *None*)
- **binary_guard** (Callable[[Project], bool] | *None*)
- **default_enabled** (*bool*)
- **suppressed_by** (*tuple[str, str, str]* | *None*)
- **claims_only** (*bool*)
- **pure_calls** (*frozenset[str]*)

**Return type**
None

**class** angr.analyses.decompiler.**KnownPatternFinder**

Bases: *Analysis*

Finds occurrences of KnownPatterns in a Clinic AIL graph.

The graph to match on is the final (SSA-form) Clinic graph, i.e. `decompiler.ail_graph` / `clinic.cc_graph`. Matches are reported in `self.matches`; `outline()` turns a match into a synthesized call by invoking the Outliner analysis on a copy of the graph.

**MAX_REMOTE_CHASE_DEPTH = 6**

**__init__**(*func*, *ail_graph*, *patterns=None*, *chase_defs=True*, *chase_remote_defs=True*, *skip_conversions=True*, *vvar_id_start=48879*, *block_addr_start=2864381952*, *ail_manager=None*, *force_patterns=None*)

`patterns` may be pattern templates (KnownPatternTemplate) and/or already-concrete KnownPatterns; templates are instantiated for this binary's PatternContext. When None, the registry is used, filtered down to the templates that are enabled for this target: default-on ones, ones named by `force_patterns`, and ones whose gate opens (see *gating*).

`force_patterns` is the user's force-enable selection, `"all"` or an iterable of template names / call names, and is only consulted when `patterns` is None (an explicit pattern list is already a selection).

**Parameters**

- **func** (Function)
- **ail_graph** (*DiGraph*)
- **patterns** (*Iterable[object]* | *None*)
- **chase_defs** (*bool*)
- **chase_remote_defs** (*bool*)
- **skip_conversions** (*bool*)
- **vvar_id_start** (*int*)

- **block_addr_start** (*int*)
- **force_patterns** (*str | Iterable[str] | None*)

**call_target_names**(*call*)

Public face of `_resolve_call_target()`, for the outliner's clean-up of calls a pattern declared pure.

**Return type**
frozenset[str]

**Parameters**
**call** (Call)

**apply_matches**(*matches*, *ail_graph*)

Apply as many of `matches` as possible, batching where it matters.

Applying one match at a time is fine until several of them interleave in one block, which is exactly what consecutive field swaps do:

**t1 = x->b; t2 = y->b; y->b = t1; x->b = t2;**
^ the next field's load sits in this one's gap

Rewrite the first and the second's statements have moved; rewrite it anyway and the third now has an opaque call sitting in its gap, which no disjointness test will let it move across. So the void statement-span matches of a block, which the finder has already checked do not conflict, are spliced in together, against the statement indices they were found at. Everything else keeps the one-at-a-time path.

Returns the new graph and the ids of the matches that were applied.

**Return type**
tuple[DiGraph, set[int]]

**Parameters**

- **matches** (*list[KnownPatternMatch]*)
- **ail_graph** (*DiGraph*)

**outline**(*match*, *ail_graph=None*)

Outline one match: split the anchor block so the matched span forms its own block, invoke the Outliner analysis on it, and rewrite the synthesized callsite into the pattern's call. Operates on (and returns) a copy; neither `self._graph` nor `ail_graph` is mutated.

**Return type**
*OutlineResult*

**Parameters**

- **match** (KnownPatternMatch)
- **ail_graph** (*DiGraph | None*)

**MAX_LIFTED_EXPR_NODES = 8**

Node budget for a lifted parameter expression; see _is_liftable.

**outline_at**(*location*, *pattern*, *ail_graph*)

Find `pattern` at `location` (`(block_addr, block_idx)` or `(block_addr, block_idx, stmt_idx)`) in `ail_graph` and outline it.

**Return type**
*OutlineResult*

**Parameters**

- **location** (*tuple[int, int] | tuple[int, int | None, int]*)
- **pattern** (KnownPattern)
- **ail_graph** (*DiGraph*)

class angr.analyses.decompiler.**KnownPatternMatch**

Bases: object

One occurrence of a KnownPattern in an AIL graph.

For expression-level matches, the boundary is `consumed_stmt_idxs` (statements wholly owned by the match, e.g. chased definitions) plus `expr_path` (the location of the matched sub-expression inside the anchor statement). For statement-sequence matches, `stmt_span` holds the ordered matched statement indices (the anchor is the first) and `matched_expr` is None.

`duplicated_stmt_idxs` holds chased definitions that are copied into the outlined region instead of moved: the originals stay where they are (other code still uses them) and the copies make the pattern's captured values the region's live-ins. It is always disjoint from `consumed_stmt_idxs`.

`recomputed_defs` does the same for definitions that live in *another* block (a CSE'd value, possibly reaching the anchor through a phi): the expression is pure, so the region recomputes it from the captured operands.

**pattern:** *KnownPattern*

**block_loc:** tuple[int, int]

**anchor_stmt_idx:** int

**expr_path:** tuple[tuple[str, int | None], ...]

**consumed_stmt_idxs:** frozenset[int]

**captures:** dict[str, *Expression*]

**matched_expr:** *Expression* | None

**duplicated_stmt_idxs:** frozenset[int] = frozenset({})

**recomputed_defs:** tuple[tuple[int, *Expression*], ...] = ()

**base_aliases:** tuple[tuple[int, int, int], ...] = ()

**stmt_span:** tuple[int, ...] | None = None

**block_map:** dict[str, tuple[int, int]] | None = None

**consumed_by_block:** dict[tuple[int, int], frozenset[int]] | None = None

**frontier_locs:** frozenset[tuple[int, int]] | None = None

**__init__**(*pattern*, *block_loc*, *anchor_stmt_idx*, *expr_path*, *consumed_stmt_idxs*, *captures*, *matched_expr*, *duplicated_stmt_idxs=frozenset({})*, *recomputed_defs=()*, *base_aliases=()*, *stmt_span=None*, *block_map=None*, *consumed_by_block=None*, *frontier_locs=None*)

**Parameters**

- **pattern** (KnownPattern)
- **block_loc** (*tuple[int, int]*)
- **anchor_stmt_idx** (*int*)
- **expr_path** (*tuple[tuple[str, int | None], ...]*)

- **consumed_stmt_idxs** (*frozenset[int]*)
- **captures** (*dict[str, Expression]*)
- **matched_expr** (*Expression | None*)
- **duplicated_stmt_idxs** (*frozenset[int]*)
- **recomputed_defs** (*tuple[tuple[int, Expression], ...]*)
- **base_aliases** (*tuple[tuple[int, int, int], ...]*)
- **stmt_span** (*tuple[int, ...] | None*)
- **block_map** (*dict[str, tuple[int, int]] | None*)
- **consumed_by_block** (*dict[tuple[int, int], frozenset[int]] | None*)
- **frontier_locs** (*frozenset[tuple[int, int]] | None*)

**Return type**
None

**class** angr.analyses.decompiler.**RegionIdentifier**

Bases: *Analysis*

A region is a single-entry-single-exit subgraph of control flow. The region identifier recursively identifies the smallest possible regions within a function graph and creates a RegionOverlay object whose nodes are either Blocks or RegionOverlays.

Note, that the analysis may modify the graph in-place. If you want to keep the original graph, set the *update_graph* parameter to False.

**__init__**(*func*, *cond_proc=None*, *graph=None*, *ail_manager=None*, *update_graph=True*, *largest_successor_tree_outside_loop=True*, *force_loop_single_exit=True*, *refine_loops_with_single_successor=False*, *expose_loop_head_backedges=False*, *force_single_loop_entry=False*, *entry_node_addr=None*)

**Parameters**

- **func** (Function)
- **cond_proc** (ConditionProcessor | *None*)
- **graph** (*networkx.DiGraph[Block] | None*)
- **ail_manager** (*Manager | None*)
- **entry_node_addr** (*tuple[int, int] | None*)

**test_reducibility**()

**Return type**
bool

**class** angr.analyses.decompiler.**RegionOverlay**

Bases: Generic[T]

A single-entry region marked over the complete graph held by an OverlayManager. The region tree is built out of RegionOverlay objects (RegionIdentifier emits them) and they are the only region type the decompiler uses.

Overlays form a tree (nested, never overlapping). An overlay's members are either complete-graph nodes it owns directly or child overlays. The region graph and the region graph-with-successors are derived on demand from the complete graph by quotienting child overlays into single nodes; *successors* are likewise derived from edges that cross the region boundary, so they can never go stale.

Read-only API (`head`, `graph`, `graph_with_successors`, `successors`, `cyclic`, `addr`) mirrors the region container consumers expect; `graph`/`graph_with_successors`/`successors` are lazy zero-copy views.

Mutation verbs:

- true structural changes (`add_node`, `remove_node`, `add_edge`, `detach_edge`, `replace_nodes`) pass through to the complete graph, so the effects are immediately visible to all enclosing regions;
- `hide_edge` removes an edge from this overlay's views only (the old "remove it from region graphs but keep the parent edge" pattern);
- `finalize(result_node)` collapses a fully-structured region into a single node of its parent;
- `dissolve()` merges an unsuccessfully-structured region back into its parent.

**__init__**(*mgr*, *head*, *cyclic*, *cyclic_ancestor=False*, *parent=None*)

**Parameters**

- **mgr** (OverlayManager*[T]*)
- **head** (Tx*[T]* | *None*)
- **cyclic** (*bool*)
- **cyclic_ancestor** (*bool*)
- **parent** (RegionOverlay | *None*)

**head**

**cyclic**

**cyclic_ancestor**

**parent**

**children: list[*RegionOverlay*]**

**edge_marks: defaultdict[str, set[tuple[*Tx*[T], *Tx*[T]]]]**

**replacement**

**property addr**

**property manager: *OverlayManager*[T]**

**property members: set[*Tx*[T]]**

**ancestors**()

All overlays enclosing this one, including this one itself.

**Return type**
set[*RegionOverlay*]

**underlying_nodes**()

All complete-graph nodes inside this region (including nodes of nested regions).

**Return type**
set[T]

**create_subregion**(*head*, *members*, *cyclic*, *cyclic_ancestor=False*)

Carve a new child overlay out of this overlay. `members` must be a subset of this overlay's members (complete-graph nodes owned by this overlay and/or existing child overlays); `head` must be one of them.

**Return type**
*RegionOverlay*[T]

**Parameters**

- **head** (*Tx[T]*)
- **members** (*Iterable*)
- **cyclic** (*bool*)
- **cyclic_ancestor** (*bool*)

**representative**(*node*)

The node standing for a complete-graph node in this overlay's with-successors view.

**Return type**
| None

**Parameters**
**node** (*T*)

**successor_nodes**()

The derived successor set of this region: representatives of all complete-graph nodes targeted by edges leaving the region.

**Return type**
set[]

**view_graph**(*full=False*, *include_marked=False*, *blacklisted_edges=frozenset({})*)

A zero-copy, networkx-compatible view of this region (see RegionOverlayGraph).

**Return type**
*RegionOverlayGraph*[T]

**Parameters**

- **full** (*bool*)
- **include_marked** (*bool*)
- **blacklisted_edges** (*frozenset*)

**view**()

The region graph (members only): a zero-copy networkx-compatible view; treat it as read-only.

**Return type**
*RegionOverlayGraph*[T]

**view_with_successors**()

The region graph including successor nodes: a zero-copy view; treat it as read-only.

**Return type**
*RegionOverlayGraph*[T]

**property raw_graph: *RegionOverlayGraph*[T]**

The member view including marked edges (the old graph with cyclic_refinement_outgoing attrs present).

property raw_graph_with_successors: *RegionOverlayGraph*[T]

The with-successors view including marked edges.

property graph: networkx.DiGraph[Tx[T]]

property graph_with_successors: networkx.DiGraph[Tx[T]]

property successors: set[*Tx*[T]]

property full_graph: None

complete_graph_entry_count(*node*)

The number of edges entering a node in the complete graph, counted over every region. For a region object, the entries of its head from outside the region (its own back edges do not count).

**Return type**
int

**Parameters**
**node** (Tx*[T]*)

external_entry_count(*node*)

The number of edges entering a node (a successor of this region) from nodes that are not under this region: the entries it keeps once every edge from this region to it has been virtualized.

**Return type**
int

**Parameters**
**node** (Tx*[T]*)

add_node(*node*)

Insert a new node into the complete graph as a direct member of this region.

**Return type**
None

remove_node(*node*, *absorbed_into=None*, *absorb_out_edges=True*)

Remove a node. If node is a member (or a member overlay's node), it is removed from the complete graph for real. If it is a successor of this region, the removal is interpreted as hiding all edges from this region to it (the successor belongs to an enclosing region and must survive).

When the node's content has been absorbed into another node during structuring, pass that node as absorbed_into: in-edges from outside this region (e.g. abnormal loop entries) are then rewired to it instead of being dropped, so enclosing regions keep their entry edges. With absorb_out_edges (the default), out-edges crossing the region boundary (e.g. loop exits) are rewired to it as well, so the complete graph never loses the region's exit flow; pass False only when the caller re-establishes every successor edge explicitly.

**Return type**
None

**Parameters**

- **node** (Tx*[T]*)
- **absorbed_into** (Tx*[T] | None*)
- **absorb_out_edges** (*bool*)

hide_edge_to_successor(*succ*)

**Return type**
None

underlying_edge_pairs(*src*, *dst*)

**Return type**
list[tuple[, ]]

**Parameters**

- **src** (Tx[T])
- **dst** (Tx[T])

add_edge(*src*, *dst*, ***data*)

Add a real edge to the complete graph. Overlay endpoints are resolved to underlying nodes: the destination resolves to its entry (head chain); overlay sources are not supported. Endpoints that are not in the complete graph yet become members of this region (mirroring networkx's implicit node creation).

**Return type**
None

**Parameters**

- **src** (Tx[T])
- **dst** (Tx[T])

detach_raw_edge(*u*, *v*)

Remove exactly one complete-graph edge. Unlike detach_edge, other edges between the view nodes representing u and v are kept (e.g. a block that jumps both to a loop's entry and into its body).

**Return type**
None

**Parameters**

- **u** (*T*)
- **v** (*T*)

detach_edge(*src*, *dst*)

Remove an edge from the complete graph for real (e.g., when the edge has been virtualized into a goto). Overlay endpoints remove all underlying edges between the two node sets.

**Return type**
None

**Parameters**

- **src** (Tx[T])
- **dst** (Tx[T])

mark_edge(*src*, *dst*, ***attrs*)

Mark a view-level edge (e.g. cyclic_refinement_outgoing) so RegionOverlayGraph hides it by default. Marks live in overlay state, never reach the complete graph, and are remapped/cleared with the region.

**Return type**
None

**Parameters**

- **src** (*Tx[T]*)
- **dst** (*Tx[T]*)

**absorb_successor_into**(*succ*, *new_node*)

Absorb a successor node into a structured member node in this region's with-successors view only (the successor still belongs to an enclosing region): the successor's view out-edges are re-attached to the member node as view-only extra edges, then the successor disappears from this region's views.

**Return type**
None

**Parameters**

- **succ** (*Tx[T]*)
- **new_node** (*Tx[T]*)

**drop_edge_marks_from**(*node*, *key*)

Clear marks on all out-edges of a node (the new_node after a replace), undoably.

**Return type**
None

**Parameters**

- **node** (*Tx[T]*)
- **key** (*str*)

**remove_edge_with_successors_only**(*src*, *dst*)

Hide an edge from the with-successors view only, leaving the member view and the complete graph alone (a rare asymmetric bookkeeping pattern in Phoenix's switch-case structuring).

**Return type**
None

**Parameters**

- **src** (*Tx[T]*)
- **dst** (*Tx[T]*)

**hide_edge**(*src*, *dst*)

Remove an edge from this overlay's views only. Enclosing regions still see the underlying edge(s).

**Return type**
None

**Parameters**

- **src** (*Tx[T]*)
- **dst** (*Tx[T]*)

**replace_nodes**(*old_node_0*, *new_node*, *old_node_1=None*, *self_loop=True*)

Replace one or two member nodes with a new node, preserving and rewiring all underlying edges (including edges from/to nodes outside this region, which is how results become visible to enclosing regions).

Mirrors StructurerBase.replace_nodes, with one deliberate difference: in-edges of `old_node_1` from outside this region are rewired to `new_node` instead of being dropped (they are entry edges owned by enclosing regions, e.g. abnormal loop entries).

**Return type**
None

**Parameters**

- **old_node_0** (*Tx[T]*)
- **new_node** (*Tx[T]*)
- **old_node_1** (*Tx[T] | None*)
- **self_loop** (*bool*)

**snapshot_successors**()

Capture this region's structural successors and how many member edges reach each, taken before the region is structured. finalize() uses it to re-establish the region-to-successor edges that structuring removes when it refines the corresponding control-flow edges into breaks, and to tell successors whose every member edge was virtualized into a goto (see detach_edge()).

**Return type**
dict[, int]

**finalize**(*result_node=None*, *succ_snapshot=None*)

Collapse this fully-structured region into its parent: the region must consist of a single member node (the structuring result), which takes the region's place among the parent's members. Returns that node.

succ_snapshot (from snapshot_successors() before structuring) is used to re-establish the edges from result_node to the region's successors: structuring may have removed the live control-flow edges (refining them into breaks), but the structured region still flows to those successors and enclosing regions must see that.

A successor whose every member edge was virtualized into a goto (detach_edge()) is a pure goto target and must NOT be reconnected. Consider a loop with two exits, where err is shared with other loops of the function:

```
    while (1) {
        if (s->bsLive >= 8) break;              // exit A: the loop successor
        if (s->strm->avail_in == 0) goto err;  // exit B: virtualized into a␣
↪goto by cyclic refinement
        refill();
    }
    uc = take_bits();                           // A
    ...
err:
    retVal = BZ_DATA_ERROR;
    goto save_state_and_return;
```

The loop region has successors A and err. Cyclic refinement keeps A as the loop successor (a break) and turns the exit to err into a goto statement, removing that edge from the complete graph. Reconnecting err here would give the loop node two successors in the parent region, one real and one fictitious: the ITE schema finds no conditions on them, the sequence schema needs a single successor, and last-resort refinement keeps both edges because each target would be orphaned, so the parent region can never be structured. With only A reconnected, the loop node is sequenced with A as usual and err stays reachable through its gotos. Cyclic refinement never virtualizes an exit that is its target's only entry in the complete graph: the region bails and dissolves into its parent, where the target is a member and the acyclic schemas structure it with the loop.

**Parameters**

- **result_node** (*Tx[T] | None*)
- **succ_snapshot** (*set[Tx[T]] | None*)

**collapse_to**(*result_node*)

Collapse this region into its parent by replacing all of its member nodes with a single external result node (the structuring result). Used by structurers that compute their result without destructively reducing the complete graph (e.g. DreamStructurer): the region's members are still present, so their crossing in/out edges are rewired onto `result_node` and the members are removed. Returns result_node.

This is the non-self-collapsing counterpart of finalize(); the legacy GraphRegion path called replace_region() for the same purpose.

**Parameters**

**result_node** (*RegionOverlay[T]*)

**dissolve**()

Merge this region back into its parent (the failure path of structuring): members are reparented, and edges hidden in this region stay hidden in the parent (matching how partially-structured region graphs were merged back before).

**Return type**

None

**class** angr.analyses.decompiler.**RegionSimplifier**

Bases: *Analysis*

Simplifies a given region.

**__init__**(*func*, *region*, *ail_manager*, *arg_vvars=None*, *simplify_switches=True*, *simplify_ifelse=True*, *variable_manager=None*, *loopctr_naming=True*)

**Parameters**

- **ail_manager** (*Manager*)
- **arg_vvars** (*set[int] | None*)
- **simplify_switches** (*bool*)
- **simplify_ifelse** (*bool*)
- **variable_manager** (*VariableManagerInternal | None*)
- **loopctr_naming** (*bool*)

**class** angr.analyses.decompiler.**SeqNodeDephication**

Bases: *DephicationBase*

SeqNodeDephication removes phi expressions from a SequenceNode and its children. It also removes redundant variable assignments, e.g., *vvar_2 = vvar_1* where both vvar_1 and vvar_2 are mapped to the same variable.

**__init__**(*func*, *seq_node*, *vvar_to_vvar_mapping=None*, *rewrite=False*, *variable_map=None*)

**Parameters**

- **func** (*Function | str*)
- **vvar_to_vvar_mapping** (*dict[int, int] | None*)
- **rewrite** (*bool*)
- **variable_map** (*VariableMap | None*)

**class** angr.analyses.decompiler.**Ssailification**

Bases: *Analysis*

Ssailification (SSA-AIL-ification) transforms an AIL graph to its partial-SSA form.

__init__(*func*, *ail_graph*, *entry=None*, *canonical_size=8*, *stack_pointer_tracker=None*, *func_addr=None*, *ail_manager=None*, *ssa_stackvars=False*, *ssa_tmps=False*, *func_args=None*, *rewrite_vvars=None*, *vvar_id_start=0*, *flavor=Flavors.DEFAULT_FLAVOR*)

**Parameters**

- **func** (*Function* | str) – The subject of the analysis: a function, or a single basic block
- **ail_graph** (networkx.DiGraph[Block]) – The AIL graph to transform.
- **canonical_size** (int) – The sizes (in bytes) that objects with an UNKNOWN_SIZE are treated as for operations where sizes are necessary.
- **entry** (*Block | None*)
- **func_addr** (*int | None*)
- **ail_manager** (*Manager | None*)
- **ssa_stackvars** (*bool*)
- **ssa_tmps** (*bool*)
- **func_args** (*set[VirtualVariable] | None*)
- **rewrite_vvars** (*set[int] | None*)
- **vvar_id_start** (*int*)
- **flavor** (*str*)

angr.analyses.decompiler.**StructuredCodeGenerator**

alias of *CStructuredCodeGenerator*

**class** angr.analyses.decompiler.**VariableMap**

Bases: object

A side container that maps the `.idx` of AIL `Statement` and `Expression` objects to variable-related information.

The following pieces of information are tracked:

- `variable` (a `SimVariable`) and `variable_offset` (an `int`): the variable that an AIL atom resolves to, and the offset into that variable.
- `custom_string` (a `bool`): whether a `Const` expression refers to a custom string.
- `reference_values` (a `dict` mapping `SimType` to a value): reference values associated with a `Const` expression (e.g., custom strings).
- `reference_variable` (a `SimVariable`) and `reference_variable_offset` (an `int`): the variable that a constant expression references, and the offset into it. These are siblings of `variable` / `variable_offset` that are specifically used for constants that reference global/extern variables.
- `prototype` (a `SimTypeFunction`) and `calling_convention` (a `SimCC`): the call-site prototype and calling convention associated with an AIL `Call` expression. These used to live directly on the `Call` object; they are heavy, non-serializable Python references, so they are tracked here instead.
- `variant` (an `EnumVariant`): the enum variant that a Rust `Let` expression binds.
- `returnty` (a `SimType`): the return type of a Rust `FunctionLikeMacro` call.

Keys are the integer `.idx` values of AIL Statement/Expression objects. Because `Clinic` builds one `ailment.Manager` per invocation, `.idx` values are unique within a single Clinic. So a VariableMap is scoped to one Clinic instance and is stored in the corresponding `DecompilationCache`.

__init__()

variable(*obj*)

**Return type**
*SimVariable* | None

**Parameters**
**obj** (*AILObject | int*)

variable_offset(*obj*)

**Return type**
int

**Parameters**
**obj** (*AILObject | int*)

custom_string(*obj*)

**Return type**
bool

**Parameters**
**obj** (*AILObject | int*)

reference_values(*obj*)

**Return type**
dict[*SimType*, Any] | None

**Parameters**
**obj** (*AILObject | int*)

reference_variable(*obj*)

**Return type**
*SimVariable* | None

**Parameters**
**obj** (*AILObject | int*)

reference_variable_offset(*obj*)

**Return type**
int

**Parameters**
**obj** (*AILObject | int*)

has_variable(*obj*)

**Return type**
bool

**Parameters**
**obj** (*AILObject | int*)

prototype(*obj*)

**Return type**
*SimTypeFunction* | None

**Parameters**
**obj** (*AILObject | int*)

**calling_convention**(*obj*)

**Return type**
*SimCC* | None

**Parameters**
**obj** (*AILObject | int*)

**variant**(*obj*)

**Return type**
Any

**Parameters**
**obj** (*AILObject | int*)

**returnty**(*obj*)

**Return type**
*SimType* | None

**Parameters**
**obj** (*AILObject | int*)

**set_variable**(*obj*, *variable*, *offset=0*)

Set the variable information for an AIL atom. If `variable` is `None`, the variable information for this atom is cleared.

**Return type**
None

**Parameters**

- **obj** (*AILObject | int*)
- **variable** (SimVariable | *None*)
- **offset** (*int*)

**set_variable_offset**(*obj*, *offset*)

**Return type**
None

**Parameters**

- **obj** (*AILObject | int*)
- **offset** (*int*)

**set_custom_string**(*obj*, *value=True*)

**Return type**
None

**Parameters**

- **obj** (*AILObject | int*)
- **value** (*bool*)

**set_reference_values**(*obj*, *reference_values*)

**Return type**
None

**Parameters**

- **obj** (*AILObject | int*)
- **reference_values** (*dict[SimType, Any]*)

**set_reference_variable**(*obj*, *variable*, *offset=0*)

Set the reference variable information for an AIL atom. If `variable` is `None`, the reference variable information for this atom is cleared.

**Return type**
None

**Parameters**

- **obj** (*AILObject | int*)
- **variable** (*SimVariable | None*)
- **offset** (*int*)

**set_prototype**(*obj*, *prototype*)

Set the call-site prototype for an AIL Call. If `prototype` is `None`, the prototype information for this atom is cleared.

**Return type**
None

**Parameters**

- **obj** (*AILObject | int*)
- **prototype** (*SimTypeFunction | None*)

**set_calling_convention**(*obj*, *cc*)

Set the calling convention for an AIL Call. If `cc` is `None`, the calling-convention information for this atom is cleared.

**Return type**
None

**Parameters**

- **obj** (*AILObject | int*)
- **cc** (*SimCC | None*)

**set_variant**(*obj*, *variant*)

Set the enum variant for a Rust `Let` expression. If `variant` is `None`, the variant information for this atom is cleared.

**Return type**
None

**Parameters**

- **obj** (*AILObject | int*)
- **variant** (*Any*)

**set_returnty**(*obj*, *returnty*)

Set the return type for a Rust `FunctionLikeMacro` call. If `returnty` is `None`, the return-type information for this atom is cleared.

**Return type**
None

**Parameters**

- **obj** (*AILObject | int*)
- **returnty** (SimType | *None*)

**transfer**(*src*, *dst*)

Copy all variable information associated with `src` to `dst`. Used when an AIL atom is deep-copied to a new `.idx` (e.g. during structuring/duplication) so that the new atom keeps the same variable association.

**Return type**
None

**Parameters**

- **src** (TaggedObject | *int*)
- **dst** (TaggedObject | *int*)

**to_json**()

Serialize this VariableMap to a JSON-compatible object.

Variables are referenced by their `.ident` (reference-by-ident); they must be resolved back to `SimVariable` objects via a resolver in `from_json()`.

**Return type**
dict[str, Any]

**classmethod from_json**(*data*, *resolve_variable*)

Deserialize a VariableMap from a JSON-compatible object produced by `to_json()`.

**Parameters**

- **data** (dict[str, Any]) – The JSON object.
- **resolve_variable** (Callable[[str], *SimVariable* | None]) – A callable that maps a variable ident (`str`) to a `SimVariable` (or `None` if it cannot be resolved).

**Return type**
*VariableMap*

### angr.analyses.decompiler.ail_simplifier

**exception** angr.analyses.decompiler.ail_simplifier.**HasVVarNotification**

Bases: Exception

Notifies the existence of a VirtualVariable.

**exception** angr.analyses.decompiler.ail_simplifier.**HasRefVVarNotification**

Bases: Exception

Notifies the existence of a reference to a VirtualVariable.

**class** angr.analyses.decompiler.ail_simplifier.**AILBlockTempCollector**

Bases: *AILBlockViewer*

Collects any temporaries used in a block.

**__init__**(***kwargs*)

**class** angr.analyses.decompiler.ail_simplifier.**DefEqRelation**

Bases: Enum

Describes the location relationship between a virtual variable definition and the equivalence statement.

**UNKNOWN = 0**

**DEF_IS_FUNCARG = 1**

**DEF_EQ_SAME_BLOCK = 2**

**DEF_IN_EQ_PRED_BLOCK = 3**

**class** angr.analyses.decompiler.ail_simplifier.**PartialConstantExprRewriter**

Bases: *AILBlockRewriter*

Rewrites expressions whose high bits are definitely zero to constants (if possible) or mask them with masks properly.

**__init__**(*varid*, *zero_high_bits*)

**Parameters**

- **varid** (*int*)
- **zero_high_bits** (*int*)

**class** angr.analyses.decompiler.ail_simplifier.**InsertLowBitsReadRewriter**

Bases: *AILBlockRewriter*

Rewrites truncating reads of Insert definitions: given `vvar = Insert(base, 0, value)`, the use `Convert(vvar.bits->value.bits, vvar)` reads back exactly the inserted value.

**__init__**(*varid*, *value_expr*)

**Parameters**

- **varid** (*int*)
- **value_expr** (Expression)

**class** angr.analyses.decompiler.ail_simplifier.**VVarToCondJumpRewriter**

Bases: *AILBlockRewriter*

Replaces uses of vvars in the conditions of ConditionalJump statements with their (pure) definitions.

**__init__**(*vvar_values*)

**Parameters**
**vvar_values** (*dict[int, Expression]*)

**walk_statement**(*stmt*, *block=None*)

**Parameters**

- **stmt** (Statement)
- **block** (*Block | None*)

**class** angr.analyses.decompiler.ail_simplifier.**AILSimplifier**

Bases: *Analysis*

Perform function-level simplifications.

**__init__**(*func*, *func_graph*, *ail_manager*, *remove_dead_memdefs=False*, *stackarg_offset_manager=None*, *unify_variables=False*, *gp=None*, *narrow_expressions=False*, *fold_expressions=True*, *only_consts=False*, *fold_callexprs_into_conditions=False*, *use_callee_saved_regs_at_return=True*, *rewrite_ccalls=True*, *rename_ccalls=True*, *rewrite_dirty=True*, *removed_vvar_ids=None*, *arg_vvars=None*, *avoid_vvar_ids=None*, *secondary_stackvars=None*, *remove_dead_assignments=True*)

**Parameters**

- **func** (Function)
- **func_graph** (*networkx.DiGraph[Block]*)
- **ail_manager** (*Manager*)
- **stackarg_offset_manager** (StackArgOffsetManager | *None*)
- **gp** (*int | None*)
- **removed_vvar_ids** (*set[int] | None*)
- **arg_vvars** (*dict[int, tuple[VirtualVariable, SimVariable]] | None*)
- **avoid_vvar_ids** (*set[int] | None*)
- **secondary_stackvars** (*set[int] | None*)
- **remove_dead_assignments** (*bool | None*)

**blocks:** dict[Block, Block]

**simplified:** bool

**simplified_blocks:** set[tuple[int, int]]

### angr.analyses.decompiler.ailgraph_walker

**exception** angr.analyses.decompiler.ailgraph_walker.**RemoveNodeNotice**

Bases: Exception

**class** angr.analyses.decompiler.ailgraph_walker.**AILGraphWalker**

Bases: object

Walks an AIL graph and optionally replaces each node with a new node.

__init__(*graph*, *handler*, *replace_nodes=False*, *strict_order_start=()*)

**Parameters**

- **graph** (*networkx.DiGraph[ailment.Block]*)
- **handler** (*Callable[[ailment.Block], ailment.Block | None]*)
- **replace_nodes** (*bool*)
- **strict_order_start** (*Sequence[ailment.Block]*)

**walk**()

angr.analyses.decompiler.ailgraph_walker.**traverse_in_order**(*ail_graph*, *entry_blocks*, *visitor*)

**Parameters**

- **ail_graph** (*networkx.DiGraph[ailment.Block]*)
- **entry_blocks** (*Sequence[ailment.Block]*)
- **visitor** (*Callable[[ailment.Block], Any]*)

### angr.analyses.decompiler.block_io_finder

**class** angr.analyses.decompiler.block_io_finder.**BlockIOFinder**

Bases: *AILBlockViewer*

Finds the input and output locations of each statement in an AIL block. I/O locations can be a Register, MemoryLocation, or SpOffset (wrapped in a Memory Location).

__init__(*ail_obj*, *project*, *as_atom=True*)

**Parameters**
**ail_obj** (*Block | list[Statement]*)

**can_swap**(*stmt*, *ail_obj*, *offset*)

**Parameters**

- **ail_obj** (*Block | list[Statement]*)
- **offset** (*int*)

### angr.analyses.decompiler.block_similarity

angr.analyses.decompiler.block_similarity.**has_similar_stmt**(*blk1*, *blk2*)

Returns True if blk1 has a statement that is similar to a statement in blk2, False otherwise.

**Parameters**

- **blk1** (*Block*)
- **blk2** (*Block*)

angr.analyses.decompiler.block_similarity.**is_similar**(*ail_obj1*, *ail_obj2*, *graph=None*, *partial=True*, *max_depth=10*, *curr_depth=0*)

Returns True if the two AIL objects are similar, False otherwise.

**Parameters**

- **ail_obj1** (*Block | Statement*)
- **ail_obj2** (*Block | Statement*)

- **graph** (*DiGraph | None*)
- **partial** (*bool*)
- **max_depth** (*int*)
- **curr_depth** (*int*)

angr.analyses.decompiler.block_similarity.**index_of_similar_stmts**(*search_stmts*, *other_stmts*, *graph=None*, *all_positions=False*)

Returns the index of the first occurrence of the search_stmts (a list of Statement) in other_stmts (a list of Statement). If all_positions is True, returns a list of all positions.

@return: None or int (position start in other)

**Return type**
int | None

angr.analyses.decompiler.block_similarity.**in_other**(*stmts*, *other*, *graph=None*)

Returns True if the stmts (a list of Statement) is found as a subsequence in other

@return:

angr.analyses.decompiler.block_similarity.**longest_ail_subseq**(*stmts_list*, *graph=None*)

Given a list of List[Statement], it returns the longest List[Statement] that is a subsequence of all the lists. The common List[Statement] most all be in the same order and adjacent to each other. If no common subsequence is found, it returns None.

**Parameters**

- **stmts_list** (list[list[*Statement*]])
- **graph**

**Return type**
tuple[list[*Statement*] | None, list[int] | None]

**Returns**
Tuple[List[Statement], List[int]], where the first element is the longest common subsequence, and the second element is a list of integers indicating the index of the longest common subsequence in each list of statements.

### angr.analyses.decompiler.block_simplifier

**class** angr.analyses.decompiler.block_simplifier.**PeepholeOptimizationBundle**

Bases: object

PeepholeOptimizationBundle describes a set of initialized peephole optimizer instances and the dispatch structures derived from them. This bundle of peephole optimizations is reusable across *BlockSimplifier* invocations (so we avoid rebuilding the same optimizer instances).

**__init__**(*project*, *kb*, *ail_manager*, *func_addr=None*, *preserve_vvar_ids=None*, *type_hints=None*, *peephole_optimizations=None*)

**Parameters**

- **ail_manager** (*Manager*)
- **func_addr** (*int | None*)
- **preserve_vvar_ids** (*set[int] | None*)

- **type_hints** (*list[tuple[VirtualVariable | MemoryLocation, str]] | None*)
- **peephole_optimizations** (*Iterable[type[PeepholeOptimizationStmtBase | PeepholeOptimizationExprBase | PeepholeOptimizationMultiStmtBase]] | None*)

**expr_opts**

**stmt_opts**

**multistmt_opts**

**stmt_opts_by_kind**

**expr_walker**

**matches**(*project*, *ail_manager*, *func_addr*, *preserve_vvar_ids*, *type_hints*, *peephole_optimizations*)

**Return type**
bool

**Parameters**

- **ail_manager** (*Manager*)
- **func_addr** (*int | None*)
- **preserve_vvar_ids** (*set[int] | None*)
- **type_hints** (*list | None*)

class angr.analyses.decompiler.block_simplifier.**BlockSimplifier**

Bases: object

Simplify an AIL block.

Deliberately not an Analysis: it is instantiated once per block, hundreds of times per decompilation, so it skips the analysis-factory ceremony. Instantiate it directly with the project as the first argument; exceptions always propagate.

**__init__**(*project*, *block*, *ail_manager*, *func_addr=None*, *stack_pointer_tracker=None*, *peephole_optimizations=None*, *preserve_vvar_ids=None*, *type_hints=None*, *cached_propagator=None*, *peephole_bundle=None*, *graph_defs=None*)

**Parameters**

- **block** (Block | None) – The AIL block to simplify. Setting it to None to skip calling self._analyze(), which is useful in test cases.
- **peephole_bundle** (*PeepholeOptimizationBundle* | None) – A pre-built PeepholeOptimizationBundle to reuse. Its construction parameters must match this BlockSimplifier's; callers that simplify many blocks should build one bundle and pass it to every BlockSimplifier they create.
- **graph_defs** (*GraphVVarDefs* | None) – Unique vvar definitions of the graph the block belongs to, for peephole optimizations that see through definitions made in other blocks.
- **project** (Project)
- **ail_manager** (*Manager*)
- **func_addr** (*int | None*)

- **peephole_optimizations** (*Iterable[type[PeepholeOptimizationStmtBase | PeepholeOptimizationExprBase | PeepholeOptimizationMultiStmtBase]] | None*)
- **preserve_vvar_ids** (*set[int] | None*)
- **type_hints** (*list[tuple[atoms.VirtualVariable | atoms.MemoryLocation, str]] | None*)

**static replace_and_build**(*block*, *replacements*, *ail_manager*, *replace_assignment_dsts=False*, *replace_loads=False*, *gp=None*, *replace_registers=True*, *max_expr_depth=13*, *max_stmt_size=20000*)

**Return type**
tuple[bool, Block]

**Parameters**

- **block** (Block)
- **replacements** (*Mapping[AILCodeLocation, Mapping[Expression, Expression]]*)
- **ail_manager** (*Manager*)
- **replace_assignment_dsts** (*bool*)
- **replace_loads** (*bool*)
- **gp** (*int | None*)
- **replace_registers** (*bool*)
- **max_expr_depth** (*int | None*)
- **max_stmt_size** (*int*)

### angr.analyses.decompiler.block_walkers

**exception** angr.analyses.decompiler.block_walkers.**HasCallNotification**

Bases: Exception

Abort the walk on the first Call / SideEffectStatement encountered.

**class** angr.analyses.decompiler.block_walkers.**HasCallExprWalker**

Bases: *AILBlockViewer*

Singleton walker that raises HasCallNotification on the first Call / SideEffectStatement it visits. Calls to pure intrinsics only have their arguments walked.

### angr.analyses.decompiler.callsite_maker

**class** angr.analyses.decompiler.callsite_maker.**CallSiteMaker**

Bases: object

Add calling convention, declaration, and args to a call site.

**__init__**(*project*, *block*, ***, *ail_manager*, *reaching_definitions=None*, *stack_pointer_tracker=None*, *x87_call_ftop=None*, *flavor=Flavors.DEFAULT_FLAVOR*)

**Parameters**

- **project** (Project)

- **ail_manager** (*Manager*)
- **reaching_definitions** (*SRDAModel | None*)
- **x87_call_ftop** (*dict[int, int] | None*)
- **flavor** (*str*)

### angr.analyses.decompiler.ccall_rewriters

#### Submodules

| |
|---|
| *amd64_ccalls* |
| *arm_ccalls* |
| *rewriter_base* |
| *x86_ccalls* |

### angr.analyses.decompiler.ccall_rewriters.amd64_ccalls

**class** angr.analyses.decompiler.ccall_rewriters.amd64_ccalls.**AMD64CCallRewriter**

Bases: *CCallRewriterBase*

Implements VEX ccall rewriter for AMD64.

### angr.analyses.decompiler.ccall_rewriters.arm_ccalls

**class** angr.analyses.decompiler.ccall_rewriters.arm_ccalls.**ARMCCallRewriter**

Bases: *CCallRewriterBase*

Rewrites ARM flag helpers following libVEX's guest_arm_helpers.c. cond_n_op packs the condition code in bits 7:4 and the cc_op in bits 3:0; odd condition codes negate their even partner.

Flag semantics per cc_op (dep_1, dep_2, dep_3):

COPY: NZCV in bits 31:28 of dep_1 ADD: res = dep_1 + dep_2; C = res <u dep_1 SUB: res = dep_1 - dep_2; C = dep_1 >=u dep_2 ADC: res = dep_1 + dep_2 + dep_3; C = res <=u dep_1 if dep_3 else res <u dep_1 SBB: res = dep_1 - dep_2 - (dep_3^1); C = dep_1 >=u dep_2 if dep_3 else dep_1 >u dep_2 LOGIC: res = dep_1; C = dep_2 (shifter carry out); V = dep_3 (old V) MUL: res = dep_1; C = dep_3[1]; V = dep_3[0] MULL: res = dep_2:dep_1; C = dep_3[1]; V = dep_3[0]

ADC with dep_3 == 0 is ADD and SBB with dep_3 == 1 is SUB. Only shapes that map exactly onto AIL expressions are rewritten; everything else is left alone.

### angr.analyses.decompiler.ccall_rewriters.rewriter_base

**class** angr.analyses.decompiler.ccall_rewriters.rewriter_base.**CCallRewriterBase**

Bases: object

The base class for CCall rewriters.

**__init__**(*ccall*, *project*, *ail_manager*, *rename_ccalls=False*, *livein_vvar_ids=None*)

**Parameters**

- **ccall** (*ailment.Expr.VEXCCallExpression*)
- **ail_manager** (*Manager*)
- **rename_ccalls** (*bool*)

### angr.analyses.decompiler.ccall_rewriters.x86_ccalls

**class** angr.analyses.decompiler.ccall_rewriters.x86_ccalls.**X86CCallRewriter**

Bases: *CCallRewriterBase*

Implements VEX ccall rewriter for X86.

From libVEX, a summary of the field usages is:

```
Operation          DEP1               DEP2               NDEP
-------------------------------------------------------------
add/sub/mul        first arg          second arg         unused
adc/sbb            first arg          (second arg)
                                      XOR old_carry      old_carry
and/or/xor         result             zero               unused
inc/dec            result             zero               old_carry
shl/shr/sar        result             subshifted-        unused
                                      result
rol/ror            result             zero               old_flags
copy               old_flags          zero               unused.
```

### angr.analyses.decompiler.clinic

**class** angr.analyses.decompiler.clinic.**BlockCache**

Bases: tuple

BlockCache(prop,)

**static __new__**(*_cls*, *prop*)

Create new instance of BlockCache(prop,)

**prop**

Alias for field number 0

**class** angr.analyses.decompiler.clinic.**ClinicMode**

Bases: Enum

Analysis mode for Clinic.

**DECOMPILE = 1**

**COLLECT_DATA_REFS = 2**

**class** angr.analyses.decompiler.clinic.**DataRefDesc**

Bases: object

The fields of this class is compatible with items inside IRSB.data_refs.

**data_addr:** int

**data_size:** int

**block_addr:** int

**stmt_idx:** int

**ins_addr:** int

**data_type_str:** str

**__init__**(*data_addr*, *data_size*, *block_addr*, *stmt_idx*, *ins_addr*, *data_type_str*)

**Parameters**

- **data_addr** (*int*)
- **data_size** (*int*)
- **block_addr** (*int*)
- **stmt_idx** (*int*)
- **ins_addr** (*int*)
- **data_type_str** (*str*)

**Return type**
None

**class** angr.analyses.decompiler.clinic.**ClinicStage**

Bases: IntEnum

Different stages of treating an ailment.

**INITIALIZATION = 0**

**AIL_GRAPH_CONVERSION = 1**

**MAKE_RETURN_SITES = 2**

**MAKE_ARGUMENT_LIST = 3**

**TRACK_STACK_POINTERS = 4**

**CONSTANT_PROPAGATION = 5**

**MAKE_CALLSITES = 6**

**POST_CALLSITES = 7**

**PRE_SSA_LEVEL0_FIXUPS = 8**

**SSA_LEVEL0_TRANSFORMATION = 9**

**PRE_SSA_LEVEL1_SIMPLIFICATIONS = 10**

**SSA_LEVEL1_TRANSFORMATION = 11**

**SEMANTIC_VARIABLE_NAMING = 14**

**COLLECT_EXTERNS = 15**

**__new__**(*value*)

**class** angr.analyses.decompiler.clinic.**ComboRegReferenceWalker**

Bases: *AILBlockRewriter*

Rewrite references to combo registers to load from the combo register.

**__init__**(*project*, *ail_manager*)

**class** angr.analyses.decompiler.clinic.**Clinic**

Bases: *Analysis*, *Serializable*

A Clinic deals with AILments: it lifts a function to AIL and runs the decompiler's simplification pipeline on it.

AIL graphs exposed after a DECOMPILE-mode run:

- `cc_graph`: the graph at the end of Clinic's own simplification, frozen as a copy before region identification. Serialized; available on both live and cached-and-reloaded clinics.
- `graph`: `cc_graph` further transformed by the decompiler's graph-simplification passes, region identification, and region-simplification passes — the final graph. Serialized; available on both live and cached-and-reloaded clinics.
- `unoptimized_graph`: a copy taken before the first structure-altering optimization pass; use it for an exact instruction-to-AIL mapping. Only built (and serialized) with `Decompiler(save_unoptimized_graph=True)`; otherwise it is None on both live and cached-and-reloaded clinics.
- `_ail_graph` / `_init_ail_graph`: pipeline internals; never serialized.

**CROSS_INSN_OPT_MIN_BLOCK_SIZE = 99**

lift a block with cross-insn-opt only when it contains at least this many bytes

**CROSS_INSN_OPT_MIN_LARGE_BLOCK_COUNT = 400**

…and only in functions with at least this many such blocks

**CROSS_INSN_OPT_MAX_BINOP_COUNT = 3**

…and it has fewer BinOps than this in total

**CROSS_INSN_OPT_MIN_STRIDE_REPEATS = 30**

…and only when the block contains this many consecutive repeating byte strides

**CROSS_INSN_OPT_MAX_STRIDE = 4**

longest byte stride when looking for repeating patterns

__init__(*func*, *remove_dead_memdefs=False*, *exception_edges=False*, *sp_tracker_track_memory=True*, *fold_expressions=True*, *fold_callexprs_into_conditions=False*, *insert_labels=True*, *optimization_passes=None*, *cfg=None*, *peephole_optimizations=None*, *must_struct=None*, *reset_variable_names=False*, *rewrite_ites_to_diamonds=True*, *rewrite_ites_to_diamond_max_cases=15*, *cache=None*, *mode=ClinicMode.DECOMPILE*, *sp_shift=0*, *inline_functions=None*, *inlined_counts=None*, *inlining_parents=None*, *vvar_id_start=0*, *optimization_scratch=None*, *desired_variables=None*, *force_loop_single_exit=True*, *refine_loops_with_single_successor=False*, *expose_loop_head_backedges=False*, *force_single_loop_entry=False*, *typehoon_cls=<class 'angr.analyses.typehoon.typehoon.Typehoon'>*, *max_ail_statements=1000000*, *max_type_constraints=100000*, *type_constraint_set_degradation_threshold=150*, *ail_graph=None*, *arg_vvars=None*, *start_stage=ClinicStage.INITIALIZATION*, *end_stage=None*, *skip_stages=()*, *notes=None*, *static_vvars=None*, *static_buffers=None*, *flatten_args=False*, *constrain_callee_prototypes=False*, *semvar_naming=True*, *flavor=Flavors.DEFAULT_FLAVOR*, *variable_map=None*, *save_unoptimized_graph=False*, *known_patterns=None*, *recognize_known_patterns=True*)

**Parameters**

- **func** (Function)
- **peephole_optimizations** (*Iterable[type[PeepholeOptimizationStmtBase | PeepholeOptimizationExprBase]] | None*)
- **must_struct** (*set[str] | None*)
- **rewrite_ites_to_diamond_max_cases** (*int*)

- **type_constraint_set_degradation_threshold** (*int*)
- **ail_graph** (*networkx.DiGraph | None*)
- **arg_vvars** (*dict[int, tuple[ailment.Expr.VirtualVariable, SimVariable]] | None*)
- **start_stage** (ClinicStage | *None*)

- **end_stage** (*ClinicStage | None*)
- **skip_stages** (*tuple[ClinicStage, ...]*)
- **notes** (*dict[str, DecompilationNote] | None*)
- **static_vvars** (*dict | None*)
- **static_buffers** (*dict | None*)
- **constrain_callee_prototypes** (*bool*)
- **semvar_naming** (*bool*)
- **flavor** (*str*)
- **variable_map** (*VariableMap | None*)
- **save_unoptimized_graph** (*bool*)
- **known_patterns** (*str | tuple[str, ...] | None*)
- **recognize_known_patterns** (*bool*)

**cc_graph:** DiGraph | None

**unoptimized_graph:** DiGraph | None

**arg_vvars:** dict[int, tuple[*VirtualVariable*, *SimVariable*]] | None

**variable_map:** *VariableMap*

**externs:** set[*SimMemoryVariable*]

**data_refs:** dict[int, list[*DataRefDesc*]]

**entry_node_addr:** Address

**unresolvable_peephole_optimizations:** list[str]

**reaching_definitions:** *SRDAModel* | None

**vvar_to_vvar:** dict[int, int] | None

**secondary_stackvars:** set[int]

**edges_to_remove:** list[tuple[Address, Address]]

**copied_var_ids:** set[int]

**typehoon:** *Typehoon* | None

**stack_items:** dict[int, *StackItem*]

**go_sigs_version:** int | None

**go_sigs_deps:** dict[str, int]

**go_sigs_updated:** bool

**go_sigs_stale:** bool

**block**(*addr*, *size*)

Get the converted block at the given specific address with the given size.

**Parameters**

- **addr** (*int*)
- **size** (*int*)

**Returns**

**dbg_repr**()

**Returns**

**calculate_stack_depth**()

**copy_graph**(*graph=None*)

**Return type**
DiGraph

**MAX_CALLEE_CLEANUP_SUBSET_CANDIDATES = 4**

**block_lifted_with_cross_insn_opt**(*block_addr*, *block_size*)

**Return type**
bool

**Parameters**

- **block_addr** (*int*)
- **block_size** (*int*)

**static repeating_stride_run**(*data*, *max_stride*)

The longest run of consecutive repetitions of up to max_stride bytes in data.

**Return type**
int

**Parameters**

- **data** (bytes)
- **max_stride** (*int*)

**static binop_count**(*block*)

The number of binary operations across all statements of block.

**Return type**
int

**Parameters**
**block** (*Block*)

**parse_variable_addr**(*addr*)

**Return type**
tuple[Any, Any]

**Parameters**
**addr** (Expression)

**new_block_addr**()

Return a block address that does not conflict with any existing blocks.

**Return type**
int

**Returns**
The block address.

**static remove_empty_nodes**(*graph*)

**Return type**
DiGraph

**Parameters**
**graph** (*DiGraph*)

**constrain_callee_prototypes**()

Constrain the types of callee function arguments based on facts that are observed at call sites. Note that this function will change the prototypes of (callee) functions in the knowledge base, which means it may affect the decompilation output of the current function if it is decompiled again.

**resolve_peephole_optimizations**()

Retry resolving peephole-optimization names that were unresolvable at parse time (their defining module may have been imported since). Resolved classes move into peephole_optimizations; names that still do not resolve stay in unresolvable_peephole_optimizations.

**Return type**
None

**classmethod parse_from_cmessage**(*cmsg*, *, *project=None*, *kb=None*, *function=None*, *cfg=None*, ***kwargs*)

Bypasses *Clinic.__init__()* (which runs the analysis) and reconstructs the instance directly. Runtime back-references — project / kb / function / _cfg — come from kwargs.

Only the state consumed by the decompiler's cache-reuse path and by post-decompilation consumers (cc_graph, graph, optionally unoptimized_graph) is serialized; regenerable and runtime-only state is restored to its default here. If function is None and kb is provided, the function is resolved by address from the cmessage.

### angr.analyses.decompiler.condition_processor

**class** angr.analyses.decompiler.condition_processor.**AILExprIdAnnotation**

Bases: Annotation

An annotation that we use to annotate BVVs so that they are differentiable between other BVVs with the same value and size.

**eliminatable = True**

**relocatable = False**

**class** angr.analyses.decompiler.condition_processor.**ConditionProcessor**

Bases: object

Convert between claripy AST and AIL expressions. Also calculates reaching conditions of all nodes on a graph.

__init__(*arch*, *ail_manager*, *condition_mapping=None*)

**Parameters**
**ail_manager** (*Manager*)

jump_table_conds: dict[int, set]

clear()

have_opposite_edge_conditions(*graph*, *src*, *dst0*, *dst1*)

Check if the edge conditions of two edges (src, dst0) and (src, dst1) are opposite to each other. Try to avoid condition translation if possible.

**Return type**
bool

**Parameters**
**graph** (*DiGraph*)

recover_edge_condition(*graph*, *src*, *dst*)

**Parameters**
**graph** (*DiGraph*)

recover_edge_conditions(*region*, *graph=None*)

**Return type**
dict

recover_reaching_conditions(*region*, *graph=None*, *with_successors=False*, *case_entry_to_switch_head=None*, *simplify_conditions=True*)

Recover the reaching conditions for each block in an acyclic graph. Note that we assume the graph that's passed in is acyclic.

**Parameters**

- **case_entry_to_switch_head** (*dict[int, int] | None*)
- **simplify_conditions** (*bool*)

remove_claripy_bool_asts(*node*, *memo=None*)

classmethod get_last_statement(*block*)

This is the buggy version of get_last_statements, because, you know, there can always be more than one last statement due to the existence of branching statements (like, If-then-else). All methods using get_last_statement() should switch to get_last_statements() and properly handle multiple last statements.

classmethod get_last_statements(*block*)

**Return type**
list[*Statement* | *ConditionalBreakNode* | *BreakNode* | *ContinueNode* | None]

EXC_COUNTER = 1000

convert_claripy_bool_ast(*cond*, *memo=None*)

Convert recovered reaching conditions from claripy ASTs to ailment Expressions

**Returns**
None

convert_claripy_bool_ast_core(*cond*, *memo*)

**claripy_ast_from_ail_condition**(*condition*, *, *nobool=False*, *must_bool=False*, *ins_addr=0*)

**Return type**
Bool | Bits

**Parameters**

- **nobool** (*bool*)
- **must_bool** (*bool*)
- **ins_addr** (*int*)

**static simplify_condition**(*cond*, *depth_limit=8*, *variables_limit=8*)

**create_jump_target_var**(*jumptable_head_addr*)

**Parameters**
**jumptable_head_addr** (*int*)

### angr.analyses.decompiler.counters

**class** angr.analyses.decompiler.counters.**AILBlockCallCounter**

Bases: *AILBlockViewer*

Helper class to count AIL calls and call-expressions in a block, or collect call statements and call expressions as well as their locations.

**__init__**(*consider_conditions=False*)

**Parameters**
**consider_conditions** (*bool*)

**class** angr.analyses.decompiler.counters.**BooleanCounter**

Bases: *AILBlockViewer*

This class counts the number of Boolean operators an expression has. In the case of: *if (a || (b && c))*, it will count 2 Boolean operators.

**__init__**()

**class** angr.analyses.decompiler.counters.**ControlFlowStructureCounter**

Bases: *SequenceWalker*

Counts the number of different types of control flow structures found in a sequence of nodes. This should be used after the sequence has been simplified.

**__init__**(*node*)

**class** angr.analyses.decompiler.counters.**OperatorCounter**

Bases: *AILBlockViewer*

Count the occurrence of a given expression operator.

**__init__**(*operator*, *expr_or_stmt*)

**Parameters**

- **operator** (*str | Iterable[str]*)
- **expr_or_stmt** (Expression | Statement)

class angr.analyses.decompiler.counters.**RegisterExpressionCounter**

Bases: *AILBlockViewer*

Count the occurrence of all register expressions in expr

**__init__**(*expr_or_stmt*)

**Parameters**
**expr_or_stmt** (Expression | Statement)

class angr.analyses.decompiler.counters.**SingleExpressionCounter**

Bases: *AILBlockViewer*

Count the occurrence of subexpr in expr.

**__init__**(*stmt*, *subexpr*)

### Submodules

*boolean_counter*
*call_counter*
*expression_counters*
*seq_cf_structure_counter*

#### angr.analyses.decompiler.counters.boolean_counter

class angr.analyses.decompiler.counters.boolean_counter.**BooleanCounter**

Bases: *AILBlockViewer*

This class counts the number of Boolean operators an expression has. In the case of: *if (a || (b && c))*, it will count 2 Boolean operators.

**__init__**()

#### angr.analyses.decompiler.counters.call_counter

class angr.analyses.decompiler.counters.call_counter.**AILBlockCallCounter**

Bases: *AILBlockViewer*

Helper class to count AIL calls and call-expressions in a block, or collect call statements and call expressions as well as their locations.

**__init__**(*consider_conditions=False*)

**Parameters**
**consider_conditions** (*bool*)

class angr.analyses.decompiler.counters.call_counter.**AILCallCounter**

Bases: *SequenceWalker*

Helper class to count AIL calls and call expressions in a structuring node, or collect call statements and call expressions as well as their locations.

**__init__**(*consider_conditions=False*)

**Parameters**
**consider_conditions** (*bool*)

### angr.analyses.decompiler.counters.expression_counters

class angr.analyses.decompiler.counters.expression_counters.**SingleExpressionCounter**

Bases: *AILBlockViewer*

Count the occurrence of subexpr in expr.

**__init__**(*stmt*, *subexpr*)

class angr.analyses.decompiler.counters.expression_counters.**RegisterExpressionCounter**

Bases: *AILBlockViewer*

Count the occurrence of all register expressions in expr

**__init__**(*expr_or_stmt*)

**Parameters**

**expr_or_stmt** (Expression | Statement)

class angr.analyses.decompiler.counters.expression_counters.**OperatorCounter**

Bases: *AILBlockViewer*

Count the occurrence of a given expression operator.

**__init__**(*operator*, *expr_or_stmt*)

**Parameters**

- **operator** (*str* | *Iterable[str]*)
- **expr_or_stmt** (Expression | Statement)

### angr.analyses.decompiler.counters.seq_cf_structure_counter

class angr.analyses.decompiler.counters.seq_cf_structure_counter.**ControlFlowStructureCounter**

Bases: *SequenceWalker*

Counts the number of different types of control flow structures found in a sequence of nodes. This should be used after the sequence has been simplified.

**__init__**(*node*)

### angr.analyses.decompiler.decompilation_cache

class angr.analyses.decompiler.decompilation_cache.**DecompilationCache**

Bases: *Serializable*

Caches key data structures that can be used later for refining decompilation results, such as retyping variables.

**__init__**(*addr*)

**parameters:** dict[str, Any]

**version:** str

**timestamp:** int

**addr**

**cfg:** *CFGModel* | None

type_constraints: dict[*TypeVariable*, set[*TypeConstraint*]]

arg_vvars: dict

func_typevar: *TypeVariable* | None

var_to_typevar: dict

stackvar_max_sizes: dict

stack_offset_typevars: dict

codegen: *BaseStructuredCodeGenerator* | None

clinic: *Clinic* | None

variable_map: *VariableMap* | None

ite_exprs: set[tuple[int, *Expression*]]

binop_operators: dict[*OpDescriptor*, str]

errors: list[str]

function_summary: str | None

notes: dict[str, *DecompilationNote*]

max_tv_id: int

go_sigs_version: int | None

go_sigs_deps: dict[str, int] | None

property local_types

classmethod parse_from_cmessage(*cmsg*, *, *project=None*, *kb=None*, *function=None*, *cfg=None*, **_)

Parse a DecompilationCache from a cmessage. Runtime back-references (project, kb, function, cfg) are passed through to the embedded Clinic / codegen parsers so the parsed cache is functional for cache-hit validity checks. Decompilation variables live on kb.dec_variables.

### angr.analyses.decompiler.decompilation_options

class angr.analyses.decompiler.decompilation_options.**DecompilationOption**

Bases: Generic[T]

Describes a decompilation option.

__init__(*name*, *description*, *value_type*, *cls*, *param*, *value_range=None*, *category='General'*, *default_value=None*, *clears_cache=True*, *candidate_values=None*, *convert=None*)

**Parameters**

- **name** (*str*)
- **description** (*str*)
- **value_type** (type[*T*])
- **cls** (*str*)
- **param** (*str*)

- **category** (*str*)
- **default_value** (*T | None*)
- **clears_cache** (*bool*)
- **candidate_values** (*list[T] | None*)
- **convert** (*Callable[[str], T] | None*)

angr.analyses.decompiler.decompilation_options.**O**

alias of *DecompilationOption*

angr.analyses.decompiler.decompilation_options.**parse_known_patterns**(*value*)

Normalize the `known_patterns` option value into `None` (force-enable nothing), the string `"all"`, or a tuple of pattern names.

Both spellings are accepted so that the GUI can offer a single text field (`"all" / "IsListEmpty, std::string::front"`) while API callers can pass a list. Names are not resolved here; that happens against the template registry, which is where an unknown name is reported.

**Return type**
str | tuple[str, ...] | None

angr.analyses.decompiler.decompilation_options.**get_structurer_option**()

**Return type**
*DecompilationOption* | None

### angr.analyses.decompiler.decompiler

**class** angr.analyses.decompiler.decompiler.**ConstantCollector**

Bases: *SequenceWalker*

Collect the values of all integer constants in a structured sequence, including the constants inside expressions and statements that structuring lifts out of blocks and onto the nodes themselves.

**__init__**()

**class** angr.analyses.decompiler.decompiler.**Decompiler**

Bases: *Analysis*

The decompiler analysis.

Run this on a Function object for which a normalized CFG has been constructed. The fully processed output can be found in result.codegen.text

AIL graphs exposed on the result (both on a fresh run and on a cache hit, including caches reloaded from angrdb or the runtime-db spill):

- `ail_graph` (= `clinic.cc_graph`): the simplified graph before region identification.
- `clinic.graph`: the final graph after region identification and region simplification.
- `unoptimized_ail_graph` (= `clinic.unoptimized_graph`): a snapshot before the first structure-altering optimization pass; use it for an exact instruction-to-AIL mapping. Only built when `save_unoptimized_graph=True` is passed; otherwise this attribute is None on both fresh runs and cache hits.

Complexity guard: pathologically large functions (e.g. packer filler that linear disassembly turns into thousands of blocks) can keep the pipeline busy indefinitely, so two size limits are checked before the expensive work starts. `max_function_blocks` (default 50000, `DEFAULT_MAX_FUNCTION_BLOCKS`) bounds the number of CFG basic blocks and is checked before any AIL is built; `max_ail_statements` (default 1000000,

DEFAULT_MAX_AIL_STATEMENTS) bounds the number of AIL statements and is checked right after the AIL graph is built. Both are ~10x the largest function in angr's test binary corpus. Either limit can be changed through the decompilation option of the same name, and setting one to 0 disables it. When a limit is exceeded, decompilation stops with an AngrDecompilationComplexityError naming the limit and the actual size: with fail_fast=True it is raised, otherwise it is recorded in self.errors (and in kb.decompilations[...].errors) and exposed as *complexity_error*, and codegen stays None.

The optimization passes come from preset (a name or a DecompilationPreset), or from an explicit optimization_passes list when no preset is given. disable_opts drops individual passes from the preset's list, which is how a caller asks for "this preset, minus that one pass" without restating it.

**__init__**(*func*, *cfg=None*, *options=None*, *preset=None*, *optimization_passes=None*, *disable_opts=None*, *sp_tracker_track_memory=True*, *peephole_optimizations=None*, *vars_must_struct=None*, *flavor=Flavors.DEFAULT_FLAVOR*, *expr_comments=None*, *stmt_comments=None*, *ite_exprs=None*, *binop_operators=None*, *decompile=True*, *regen_clinic=False*, *inline_functions=None*, *desired_variables=None*, *update_memory_data=True*, *want_full_graph=False*, *generate_code=True*, *use_cache=True*, *update_cache=True*, *expr_collapse_depth=16*, *clinic_graph=None*, *clinic_arg_vvars=None*, *clinic_start_stage=None*, *clinic_end_stage=None*, *clinic_skip_stages=()*, *static_vvars=None*, *static_buffers=None*, *codegen_cls=<class 'angr.analyses.decompiler.structured_codegen.c.CStructuredCodeGenerator'>*, *save_unoptimized_graph=False*, *go_sigs_rerun=True*)

**Parameters**

- **func** (Function | *str* | *int*)
- **cfg** (CFGFast | CFGModel | *None*)
- **preset** (*str* | DecompilationPreset | *None*)
- **peephole_optimizations** (*_PEEPHOLE_OPTIMIZATIONS_TYPE*)
- **vars_must_struct** (*set[str]* | *None*)
- **flavor** (*str*)
- **update_memory_data** (*bool*)
- **want_full_graph** (*bool*)
- **generate_code** (*bool*)
- **use_cache** (*bool*)
- **update_cache** (*bool*)
- **expr_collapse_depth** (*int*)
- **static_vvars** (*dict* | *None*)
- **static_buffers** (*dict* | *None*)
- **save_unoptimized_graph** (*bool*)
- **go_sigs_rerun** (*bool*)

**property complexity_error:** *AngrDecompilationComplexityError* | None

The complexity-limit violation that aborted this decompilation, or None if no limit was exceeded. Inspect limit_name, limit, and actual on it to decide whether to raise the limit or skip the function.

**reflow_variable_types**(*cache*)

Re-run type inference on an existing variable recovery result, then rerun codegen to generate new results.

**Returns**

**Parameters**
**cache** (DecompilationCache)

**find_data_references_and_update_memory_data**(*seq_node*)

**Parameters**
**seq_node** (SequenceNode)

**transform_graph_from_ssa**(*ail_graph*)

Translate an SSA AIL graph out of SSA form. This is useful for producing a non-SSA AIL graph for displaying in angr management.

**Parameters**
**ail_graph** (DiGraph) – The AIL graph to transform out of SSA form.

**Return type**
DiGraph

**Returns**
The translated AIL graph.

**transform_seqnode_from_ssa**(*seq_node*)

**Return type**
*SequenceNode*

**Parameters**
**seq_node** (SequenceNode)

**llm_refine**()

Use the configured LLM to suggest improved variable names, function names, and variable types. Returns True if any changes were made.

**Return type**
bool

**llm_suggest_variable_names**(*llm_client=None*, *code_text=None*, *raise_exc=False*)

Ask the LLM to suggest better variable names for the decompiled code. Returns True if any variables were renamed.

**Parameters**

- **raise_exc** (bool) – If True, exceptions from the LLM call are propagated to the caller. If False (default), exceptions are caught and the method returns False.
- **code_text** (*str | None*)

**Return type**
bool

**llm_suggest_function_name**(*llm_client=None*, *code_text=None*, *raise_exc=False*)

Ask the LLM to suggest a better function name. Only suggests rename for auto-generated names (starting with sub_ or fcn.). Returns True if the function was renamed.

**Parameters**

- **raise_exc** (bool) – If True, exceptions from the LLM call are propagated to the caller.
- **code_text** (*str | None*)

**Return type**
bool

**llm_suggest_variable_types**(*llm_client=None*, *code_text=None*, *raise_exc=False*)

Ask the LLM to suggest better C types for variables. Returns True if any variable types were changed.

**Parameters**

- **raise_exc** (bool) – If True, exceptions from the LLM call are propagated to the caller.
- **code_text** (*str | None*)

**Return type**
bool

**llm_summarize_function**(*llm_client=None*, *code_text=None*, *raise_exc=False*)

Ask the LLM to produce a natural-language summary of what the decompiled function does. The summary is stored in the DecompilationCache and returned.

Returns the summary string, or None if summarization failed.

**Parameters**

- **raise_exc** (bool) – If True, exceptions from the LLM call are propagated to the caller.
- **code_text** (*str | None*)

**Return type**
str | None

**static options_to_params**(*options*)

Convert decompilation options to a dict of params.

**Parameters**
**options** (list[tuple[*DecompilationOption*, Any]]) – The decompilation options.

**Return type**
dict[str, Any]

**Returns**
A dict of keyword arguments.

### angr.analyses.decompiler.dephication

**class** angr.analyses.decompiler.dephication.**GraphDephication**

Bases: *DephicationBase*

GraphDephication removes phi expressions from an AIL graph, essentially transforms a partial-SSA form of AIL graph to a normal AIL graph.

**__init__**(*func*, *ail_graph*, *vvar_to_vvar_mapping=None*, *rewrite=False*, *variable_map=None*)

**Parameters**

- **func** (*Function* | str) – The subject of the analysis: a function, or a single basic block
- **ail_graph** – The AIL graph to transform.
- **vvar_to_vvar_mapping** (*dict[int, int] | None*)
- **rewrite** (*bool*)
- **variable_map** (VariableMap *| None*)

class angr.analyses.decompiler.dephication.**GraphDephicationVVarMapping**

Bases: *Analysis*

GraphDephicationVVarMapping collects information from an AIL graph regarding how virtual variables should be mapped to each other in order to remove phi variables. This mapping will later be used to transform a partial-SSA form of AIL graph to a conventional AIL graph.

This class largely implements "Translating Out of Static Single Assignment Form" by Sreedhar et al.

**__init__**(*func*, *ail_graph*, *ail_manager*, *entry=None*, *vvar_id_start=0*, *arg_vvars=None*)

**Parameters**

- **func** (*Function* | str) – The subject of the analysis: a function, or a single basic block
- **ail_graph** – The AIL graph to transform.
- **ail_manager** (*Manager*)
- **vvar_id_start** (*int*)
- **arg_vvars** (*list[VirtualVariable] | None*)

class angr.analyses.decompiler.dephication.**SeqNodeDephication**

Bases: *DephicationBase*

SeqNodeDephication removes phi expressions from a SequenceNode and its children. It also removes redundant variable assignments, e.g., *vvar_2 = vvar_1* where both vvar_1 and vvar_2 are mapped to the same variable.

**__init__**(*func*, *seq_node*, *vvar_to_vvar_mapping=None*, *rewrite=False*, *variable_map=None*)

**Parameters**

- **func** (*Function | str*)
- **vvar_to_vvar_mapping** (*dict[int, int] | None*)
- **rewrite** (*bool*)
- **variable_map** (*VariableMap | None*)

## Submodules

*graph_vvar_mapping*
*rewriting_engine*
*seqnode_dephication*

### angr.analyses.decompiler.dephication.dephication_base

class angr.analyses.decompiler.dephication.dephication_base.**DephicationBase**

Bases: *Analysis*

This is the base class for analyses that removes phi expressions from AIL graphs, SequenceNodes, and other types of AIL statement containers.

**__init__**(*func*, *vvar_to_vvar_mapping=None*, *rewrite=False*, *variable_map=None*)

**Parameters**

- **vvar_to_vvar_mapping** (*dict[int, int] | None*)
- **rewrite** (*bool*)
- **variable_map** (*VariableMap | None*)

### angr.analyses.decompiler.dephication.graph_dephication

**class** angr.analyses.decompiler.dephication.graph_dephication.**GraphDephication**

Bases: *DephicationBase*

GraphDephication removes phi expressions from an AIL graph, essentially transforms a partial-SSA form of AIL graph to a normal AIL graph.

**__init__**(*func*, *ail_graph*, *vvar_to_vvar_mapping=None*, *rewrite=False*, *variable_map=None*)

**Parameters**

- **func** (*Function* | str) – The subject of the analysis: a function, or a single basic block
- **ail_graph** – The AIL graph to transform.
- **vvar_to_vvar_mapping** (*dict[int, int] | None*)
- **rewrite** (*bool*)
- **variable_map** (*VariableMap | None*)

### angr.analyses.decompiler.dephication.graph_rewriting

**class** angr.analyses.decompiler.dephication.graph_rewriting.**GraphRewritingAnalysis**

Bases: *ForwardAnalysis*[None, , object, object, object]

This analysis traverses the AIL graph and rewrites virtual variables accordingly.

### angr.analyses.decompiler.dephication.graph_vvar_mapping

**class** angr.analyses.decompiler.dephication.graph_vvar_mapping.**GraphDephicationVVarMapping**

Bases: *Analysis*

GraphDephicationVVarMapping collects information from an AIL graph regarding how virtual variables should be mapped to each other in order to remove phi variables. This mapping will later be used to transform a partial-SSA form of AIL graph to a conventional AIL graph.

This class largely implements "Translating Out of Static Single Assignment Form" by Sreedhar et al.

**__init__**(*func*, *ail_graph*, *ail_manager*, *entry=None*, *vvar_id_start=0*, *arg_vvars=None*)

**Parameters**

- **func** (*Function* | str) – The subject of the analysis: a function, or a single basic block
- **ail_graph** – The AIL graph to transform.
- **ail_manager** (*Manager*)
- **vvar_id_start** (*int*)
- **arg_vvars** (*list[VirtualVariable] | None*)

### angr.analyses.decompiler.dephication.rewriting_engine

**class** angr.analyses.decompiler.dephication.rewriting_engine.**SimEngineDephiRewriting**

Bases: *SimEngineNostmtAIL*[None, *Expression* | None, *Statement* | tuple[*Statement*, ...], None]

This engine rewrites every block to insert phi variables and replaces every used variable with their versioned copies at each use location.

**state:** None

**__init__**(*project*, *vvar_to_vvar*, *func_addr=None*, *kb=None*, *variable_map=None*)

**Parameters**

- **vvar_to_vvar** (*dict[int, int]*)
- **func_addr** (*int | None*)
- **kb** (KnowledgeBase | *None*)
- **variable_map** (VariableMap | *None*)

**append_statement**(*stmt*)

**Return type**
None

**Parameters**
**stmt** (Statement)

### angr.analyses.decompiler.dephication.seqnode_dephication

**class** angr.analyses.decompiler.dephication.seqnode_dephication.**PhiAssignmentCollector**

Bases: *SequenceWalker*

PhiAssignmentCollector collects all phi variables and their corresponding source virtual variables in a SequenceNode.

**__init__**(*seq_node*)

**Parameters**
**seq_node** (SequenceNode)

**class** angr.analyses.decompiler.dephication.seqnode_dephication.**SeqNodeRewriter**

Bases: *SequenceWalker*

SeqNodeRewriter rewrites a SequenceNode by replacing all phi variables with their corresponding source virtual variables.

**__init__**(*seq_node*, *vvar_to_vvar*, *project*, *func_addr=None*, *kb=None*, *variable_map=None*)

**Parameters**

- **seq_node** (SequenceNode)
- **vvar_to_vvar** (*dict[int, int]*)
- **project** (*angr.Project*)
- **func_addr** (*int | None*)
- **kb** (KnowledgeBase | *None*)
- **variable_map** (VariableMap | *None*)

class angr.analyses.decompiler.dephication.seqnode_dephication.**SeqNodeDephication**

Bases: *DephicationBase*

SeqNodeDephication removes phi expressions from a SequenceNode and its children. It also removes redundant variable assignments, e.g., *vvar_2 = vvar_1* where both vvar_1 and vvar_2 are mapped to the same variable.

**__init__**(*func*, *seq_node*, *vvar_to_vvar_mapping=None*, *rewrite=False*, *variable_map=None*)

**Parameters**

- **func** (*Function | str*)
- **vvar_to_vvar_mapping** (*dict[int, int] | None*)
- **rewrite** (*bool*)
- **variable_map** (*VariableMap | None*)

### angr.analyses.decompiler.dirty_rewriters

### Submodules

*amd64_dirty*
*rewriter_base*
*x86_dirty*

### angr.analyses.decompiler.dirty_rewriters.amd64_dirty

class angr.analyses.decompiler.dirty_rewriters.amd64_dirty.**AMD64DirtyRewriter**

Bases: *X86DirtyRewriter*

Rewrites AMD64 DirtyStatement and DirtyExpression. The helpers mirror the X86 ones under a different prefix.

**HELPER_PREFIX = 'amd64g_dirtyhelper_'**

### angr.analyses.decompiler.dirty_rewriters.rewriter_base

class angr.analyses.decompiler.dirty_rewriters.rewriter_base.**DirtyRewriterBase**

Bases: object

The base class for DirtyStatement and DirtyExpression rewriters.

**__init__**(*dirty*, *arch*, *manager*)

**Parameters**

- **dirty** (*DirtyExpression | DirtyStatement*)
- **manager** (*Manager*)

**arch**

**manager**

**result:** *Expression* | *Statement* | None

### angr.analyses.decompiler.dirty_rewriters.x86_dirty

**class** angr.analyses.decompiler.dirty_rewriters.x86_dirty.**X86DirtyRewriter**

Bases: *DirtyRewriterBase*

Rewrites X86 DirtyStatement and DirtyExpression: x87 80-bit loads/stores become memory accesses, every other "<arch>g_dirtyhelper_*" call becomes an opaque intrinsic call with a prototype.

**HELPER_PREFIX = 'x86g_dirtyhelper_'**

### angr.analyses.decompiler.edits

Knowledge-base edits for decompilation output: renaming, retyping, and commenting.

This layer is deliberately free of any UI or transport dependency so both the headless MCP server and angr-management drive the same code. It is *not* thread-safe: locking belongs to whoever owns the knowledge base's lifetime.

**exception** angr.analyses.decompiler.edits.**AmbiguousFunctionError**

Bases: *DecompilationEditError*

More than one function matches the given name. Renames make this reachable.

**exception** angr.analyses.decompiler.edits.**DecompilationEditError**

Bases: *AngrError*

Base class for every failure raised by the decompilation edit layer.

**class** angr.analyses.decompiler.edits.**EditHooks**

Bases: Protocol

Notifications fired immediately *before* each mutation, while the old value is still readable from the knowledge base.

The method set mirrors angr-management's plugin hooks one-for-one so its adapter is a pure forwarder. Firing before the mutation matches what the GUI's own edit dialogs do, and is what lets a handler snapshot pre-edit state.

**before_function_renamed**(*func*, *old_name*, *new_name*)

**Return type**
None

**Parameters**

- **func** (Function)
- **old_name** (*str*)
- **new_name** (*str*)

**before_stack_var_renamed**(*func*, *offset*, *old_name*, *new_name*)

**Return type**
None

**Parameters**

- **func** (Function)
- **offset** (*int*)
- **old_name** (*str*)
- **new_name** (*str*)

before_func_arg_renamed(*func*, *arg_index*, *old_name*, *new_name*)

**Return type**
None

**Parameters**

- **func** (Function)
- **arg_index** (*int*)
- **old_name** (*str*)
- **new_name** (*str*)

before_global_var_renamed(*addr*, *old_name*, *new_name*)

**Return type**
None

**Parameters**

- **addr** (*int*)
- **old_name** (*str*)
- **new_name** (*str*)

before_stack_var_retyped(*func*, *offset*, *old_type*, *new_type*)

**Return type**
None

**Parameters**

- **func** (Function)
- **offset** (*int*)
- **old_type** (SimType | *None*)
- **new_type** (SimType)

before_func_arg_retyped(*func*, *arg_index*, *old_type*, *new_type*)

**Return type**
None

**Parameters**

- **func** (Function)
- **arg_index** (*int*)
- **old_type** (SimType | *None*)
- **new_type** (SimType)

before_global_var_retyped(*addr*, *old_type*, *new_type*)

**Return type**
None

**Parameters**

- **addr** (*int*)
- **old_type** (SimType | *None*)

- **new_type** (SimType)

**before_other_var_retyped**(*var*, *old_type*, *new_type*)

**Return type**
None

**Parameters**

- **var** (SimVariable)
- **old_type** (SimType | *None*)
- **new_type** (SimType)

**before_function_retyped**(*func*, *old_proto*, *new_proto*)

**Return type**
None

**Parameters**

- **func** (Function)
- **old_proto** (SimTypeFunction | *None*)
- **new_proto** (SimTypeFunction)

**before_comment_changed**(*addr*, *old*, *new*, *created*, *decomp*)

**Return type**
None

**Parameters**

- **addr** (*int*)
- **old** (*str*)
- **new** (*str*)
- **created** (*bool*)
- **decomp** (*bool*)

**__init__**(**args*, ***kwargs*)

class angr.analyses.decompiler.edits.**EditResult**

Bases: object

The outcome of a single edit. changed is False when the edit was a no-op.

**changed:** bool

**kind:** str

**func_addr:** int | None = None

**old:** Any = None

**new:** Any = None

**refresh:** *Refresh*

**detail:** dict[str, Any]

**__init__**(*changed*, *kind*, *func_addr=None*, *old=None*, *new=None*, *refresh=<factory>*, *detail=<factory>*)

**Parameters**

- **changed** (*bool*)
- **kind** (*str*)
- **func_addr** (*int | None*)
- **old** (*Any*)
- **new** (*Any*)
- **refresh** (Refresh)
- **detail** (*dict[str, Any]*)

**Return type**
None

**exception** angr.analyses.decompiler.edits.**FunctionNotFoundError**

Bases: *DecompilationEditError*

No function matches the given address or name.

**exception** angr.analyses.decompiler.edits.**InvalidNameError**

Bases: *DecompilationEditError*

The requested name is not a usable identifier.

**exception** angr.analyses.decompiler.edits.**NameCollisionError**

Bases: *DecompilationEditError*

The requested name is already bound to a different function, variable, or label.

**exception** angr.analyses.decompiler.edits.**NotDecompiledError**

Bases: *DecompilationEditError*

The function has no cached decompilation, so there is nothing to edit.

**class** angr.analyses.decompiler.edits.**NullEditHooks**

Bases: object

A concrete no-op implementation. Subclass it so an adapter only overrides what it needs.

**before_function_renamed**(*func*, *old_name*, *new_name*)

**Return type**
None

**Parameters**

- **func** (Function)
- **old_name** (*str*)
- **new_name** (*str*)

**before_stack_var_renamed**(*func*, *offset*, *old_name*, *new_name*)

**Return type**
None

**Parameters**

- **func** (Function)

- **offset** (*int*)
- **old_name** (*str*)
- **new_name** (*str*)

**before_func_arg_renamed**(*func*, *arg_index*, *old_name*, *new_name*)

**Return type**
None

**Parameters**

- **func** (Function)
- **arg_index** (*int*)
- **old_name** (*str*)
- **new_name** (*str*)

**before_global_var_renamed**(*addr*, *old_name*, *new_name*)

**Return type**
None

**Parameters**

- **addr** (*int*)
- **old_name** (*str*)
- **new_name** (*str*)

**before_stack_var_retyped**(*func*, *offset*, *old_type*, *new_type*)

**Return type**
None

**Parameters**

- **func** (Function)
- **offset** (*int*)
- **old_type** (SimType | *None*)
- **new_type** (SimType)

**before_func_arg_retyped**(*func*, *arg_index*, *old_type*, *new_type*)

**Return type**
None

**Parameters**

- **func** (Function)
- **arg_index** (*int*)
- **old_type** (SimType | *None*)
- **new_type** (SimType)

**before_global_var_retyped**(*addr*, *old_type*, *new_type*)

**Return type**
None

**Parameters**

- **addr** (*int*)
- **old_type** (SimType | *None*)
- **new_type** (SimType)

**before_other_var_retyped**(*var*, *old_type*, *new_type*)

**Return type**
None

**Parameters**

- **var** (SimVariable)
- **old_type** (SimType | *None*)
- **new_type** (SimType)

**before_function_retyped**(*func*, *old_proto*, *new_proto*)

**Return type**
None

**Parameters**

- **func** (Function)
- **old_proto** (SimTypeFunction | *None*)
- **new_proto** (SimTypeFunction)

**before_comment_changed**(*addr*, *old*, *new*, *created*, *decomp*)

**Return type**
None

**Parameters**

- **addr** (*int*)
- **old** (*str*)
- **new** (*str*)
- **created** (*bool*)
- **decomp** (*bool*)

**class** angr.analyses.decompiler.edits.**Refresh**

Bases: object

What a caller has to redo after an edit.

Lets a UI pick between re-rendering text, rebuilding the codegen AST, and a full re-decompilation instead of guessing. `text_stale_all` means every cached decompilation's rendered text is stale (a function rename changes call sites everywhere), but the caller should re-render lazily: eagerly re-rendering the whole cache would thrash its LRU.

**text_stale:** frozenset[int] = frozenset({})

**text_stale_all:** bool = False

**reanalyze:** frozenset[int] = frozenset({})

**redecompile:** frozenset[int] = frozenset({})

**function_list_dirty:** bool = False

**disassembly_dirty:** bool = False

**merge**(*other*)

**Return type**
*Refresh*

**Parameters**
**other** (Refresh)

**__init__**(*text_stale=frozenset({})*, *text_stale_all=False*, *reanalyze=frozenset({})*, *redecompile=frozenset({})*, *function_list_dirty=False*, *disassembly_dirty=False*)

**Parameters**

- **text_stale** (*frozenset[int]*)
- **text_stale_all** (*bool*)
- **reanalyze** (*frozenset[int]*)
- **redecompile** (*frozenset[int]*)
- **function_list_dirty** (*bool*)
- **disassembly_dirty** (*bool*)

**Return type**
None

**class** angr.analyses.decompiler.edits.**ResolvedVariable**

Bases: object

A pseudocode display name resolved to the objects an edit needs.

`variable` is the concrete/SSA variable that `set_variable_type` expects; `unified` is the unified variable that a rename mutates (None for globals, which have no unified form).

**kind:** Literal['argument', 'local', 'global']

**variable:** *SimVariable*

**unified:** *SimVariable* | None

**cvar:** *CVariable* | None = None

**arg_index:** int | None = None

**stack_offset:** int | None = None

**global_addr:** int | None = None

**ambiguous:** bool = False

**property name:** str | None

**property storage:** str

**detail**()

**Return type**
dict

**__init__**(*kind*, *variable*, *unified*, *cvar=None*, *arg_index=None*, *stack_offset=None*, *global_addr=None*, *ambiguous=False*)

**Parameters**

- **kind** (*VariableKind*)
- **variable** (SimVariable)
- **unified** (SimVariable | *None*)
- **cvar** (CVariable | *None*)
- **arg_index** (*int* | *None*)
- **stack_offset** (*int* | *None*)
- **global_addr** (*int* | *None*)
- **ambiguous** (*bool*)

**Return type**
None

**exception** angr.analyses.decompiler.edits.**TypeParseError**

Bases: *DecompilationEditError*

A C type declaration or function signature could not be parsed.

**exception** angr.analyses.decompiler.edits.**UnsupportedEditError**

Bases: *DecompilationEditError*

The requested edit is not supported for this kind of target.

**exception** angr.analyses.decompiler.edits.**VariableNotFoundError**

Bases: *DecompilationEditError*

No variable in the decompilation matches the given display name.

`candidates` carries the names that *are* available, so a caller that failed can correct itself without a second round trip.

angr.analyses.decompiler.edits.**concrete_variables**(*varman*, *resolved*)

Every SSA variable sharing the resolved variable's unified form.

Retyping applies to all of them. Computed here rather than relying on `set_variable_type(all_unified=True)`, which silently does nothing when the variable it is handed is not a key in the SSA-to-unified map.

**Return type**
list[*SimVariable*]

**Parameters**
**resolved** (ResolvedVariable)

angr.analyses.decompiler.edits.**get_cache**(*kb*, *func_addr*, *flavor=Flavors.DEFAULT_FLAVOR*)

Return the cached decompilation for a function, or None if there is none.

**Return type**
*DecompilationCache* | None

**Parameters**

- **kb** (KnowledgeBase)
- **func_addr** (*int*)
- **flavor** (*str*)

angr.analyses.decompiler.edits.**global_variable_at**(*kb*, *addr*, *flavor=Flavors.DEFAULT_FLAVOR*)

The global SimVariable recorded at an address by a decompilation of the flavor, if there is one.

**Return type**
*SimMemoryVariable* | None

**Parameters**

- **kb** (KnowledgeBase)
- **addr** (*int*)
- **flavor** (*str*)

angr.analyses.decompiler.edits.**invalidate**(*kb*, *func_addr*, ***, *flavors=None*, *drop_variables=False*)

Drop cached decompilations for a function.

**Parameters**

- **flavors** (Iterable[str] | None) – Flavors to drop; None drops every flavor currently cached. A prototype change must drop all of them, or a non-pseudocode flavor silently retains the old signature.
- **drop_variables** (bool) – Also drop `kb.dec_variables[func_addr]`. Required for new argument names to take effect, but it discards every rename and manual type for the function – see `snapshot_user_edits()`.
- **kb** (KnowledgeBase)
- **func_addr** (*int*)

**Return type**
None

angr.analyses.decompiler.edits.**list_variable_names**(*codegen*, *kb=None*, *func_addr=None*)

Every display name addressable in this decompilation, for error messages.

**Return type**
list[str]

**Parameters**

- **kb** (KnowledgeBase | *None*)
- **func_addr** (*int* | *None*)

angr.analyses.decompiler.edits.**parse_address**(*value*)

Parse an address given as an int or a string. Accepts 0x-prefixed hex and decimal.

**Return type**
int

**Parameters**
**value** (*str* | *int*)

angr.analyses.decompiler.edits.**reflow_types**(*project*, *func*, ***, *kb=None*, *flavor=Flavors.DEFAULT_FLAVOR*, *rerender=True*)

Re-run type inference over the cached constraints and refresh the rendered code.

Separate from `set_variable_type()` so a batch can retype many variables and reflow once; per-variable reflow would re-run Typehoon N times.

This is not a re-decompilation: the AST is untouched, so a retype that should change how an access renders (a struct field, an array index) needs a full re-decompilation instead.

**Parameters**

- **project** (Project)
- **func** (Function)
- **kb** (KnowledgeBase | *None*)
- **flavor** (*str*)
- **rerender** (*bool*)

angr.analyses.decompiler.edits.**rename_function**(*project*, *func*, *new_name*, ***, *kb=None*, *hooks=None*, *flavor=Flavors.DEFAULT_FLAVOR*, *allow_overwrite=True*, *strict_names=True*, *rerender=True*)

Rename a function.

Nothing is invalidated: other functions' cached ASTs reference the same Function object, so only their rendered text goes stale. That is reported through `Refresh.text_stale_all` for the caller to act on lazily.

**Return type**
*EditResult*

**Parameters**

- **project** (Project)
- **func** (Function)
- **new_name** (*str*)
- **kb** (KnowledgeBase | *None*)
- **hooks** (EditHooks | *None*)
- **flavor** (*str*)
- **allow_overwrite** (*bool*)
- **strict_names** (*bool*)
- **rerender** (*bool*)

angr.analyses.decompiler.edits.**rename_global**(*project*, *addr*, *new_name*, ***, *kb=None*, *hooks=None*, *allow_overwrite=True*, *strict_names=True*)

Rename a global by address, without needing a function whose decompilation shows it.

**Return type**
*EditResult*

**Parameters**

- **project** (Project)
- **addr** (*int*)

- **new_name** (*str*)
- **kb** (KnowledgeBase | *None*)
- **hooks** (EditHooks | *None*)
- **allow_overwrite** (*bool*)
- **strict_names** (*bool*)

angr.analyses.decompiler.edits.**rename_variable**(*project*, *func*, *variable_name*, *new_name*, ***, *kb=None*, *hooks=None*, *flavor=Flavors.DEFAULT_FLAVOR*, *allow_overwrite=True*, *strict_names=True*, *rerender=True*, *codegen=None*)

Rename a local, an argument, or a global as it appears in a function's decompilation.

Sets `renamed` on the variable, without which a later re-decompilation overwrites the name.

**Return type**
*EditResult*

**Parameters**

- **project** (Project)
- **func** (Function)
- **variable_name** (*str*)
- **new_name** (*str*)
- **kb** (KnowledgeBase | *None*)
- **hooks** (EditHooks | *None*)
- **flavor** (*str*)
- **allow_overwrite** (*bool*)
- **strict_names** (*bool*)
- **rerender** (*bool*)

angr.analyses.decompiler.edits.**require_cache**(*kb*, *func_addr*, *flavor=Flavors.DEFAULT_FLAVOR*)

Return the cached decompilation, raising NotDecompiledError if it is missing or empty.

**Return type**
*DecompilationCache*

**Parameters**

- **kb** (KnowledgeBase)
- **func_addr** (*int*)
- **flavor** (*str*)

angr.analyses.decompiler.edits.**resolve_function**(*kb*, ***, *address=None*, *name=None*, *containing=True*)

Find a function by address or by name.

**Parameters**

- **containing** (bool) – If True, an address inside a function resolves to that function rather than requiring the exact entry address.
- **kb** (KnowledgeBase)
- **address** (*str* | *int* | *None*)

- **name** (*str | None*)

**Return type**
*Function*

angr.analyses.decompiler.edits.**resolve_variable**(*kb*, *func_addr*, *display_name*, *, *codegen=None*, *flavor=Flavors.DEFAULT_FLAVOR*)

Resolve a name as it appears in the pseudocode to the underlying variable.

Precedence is argument > local > global. A name matching more than one variable within the same bucket resolves deterministically and sets `ambiguous`, rather than failing – a batch edit should be able to report the collision and continue.

**Return type**
*ResolvedVariable*

**Parameters**

- **kb** (KnowledgeBase)
- **func_addr** (*int*)
- **display_name** (*str*)
- **flavor** (*str*)

angr.analyses.decompiler.edits.**restore_user_edits**(*kb*, *func_addr*, *snapshot*)

Re-apply a `snapshot_user_edits()` result after re-decompilation.

Best-effort: idents can change across a re-decompile, so the unmatched ones are returned rather than silently dropped.

**Return type**
tuple[int, list[str]]

**Parameters**

- **kb** (KnowledgeBase)
- **func_addr** (*int*)
- **snapshot** (*dict[str, tuple[str | None, SimType | None]]*)

angr.analyses.decompiler.edits.**set_comment**(*project*, *addr*, *comment*, *, *kind=None*, *kb=None*, *hooks=None*, *flavor=Flavors.DEFAULT_FLAVOR*, *mirror_to_pseudocode=True*, *snap=True*, *rerender=True*)

Set the comment at an address, or clear it with an empty string or None.

The comment goes into kb.comments, which the disassembly renders and which the decompiler reads for the function header. Per-statement pseudocode comments live in codegen.stmt_comments instead, so both are written – except at the function entry, where kb.comments is already what the header renders and mirroring would show the comment twice.

`kind` sets the comment's display kind; None keeps whatever kind the comment already has. Clearing a comment always clears its kind.

**Return type**
*EditResult*

**Parameters**

- **project** (Project)
- **addr** (*int*)

- **comment** (*str | None*)
- **kind** (CommentKind | *None*)
- **kb** (KnowledgeBase | *None*)
- **hooks** (EditHooks | *None*)
- **flavor** (*str*)
- **mirror_to_pseudocode** (*bool*)
- **snap** (*bool*)
- **rerender** (*bool*)

angr.analyses.decompiler.edits.**set_function_prototype**(*project*, *func*, *prototype*, ***, *kb=None*, *hooks=None*, *flavor=Flavors.DEFAULT_FLAVOR*, *invalidate_cache=True*, *preserve_user_edits=True*, *redecompile=False*)

Set a function's prototype.

The function name inside the signature is ignored; use `rename_function()` to rename.

Dropping kb.dec_variables is what makes new argument names take effect, but it also discards every rename and manual type for the function. Those are snapshotted and, when this function re-decompiles, restored. Otherwise the snapshot is returned in `detail["user_edits"]` so a caller that decompiles asynchronously can restore it once its own job finishes.

**Return type**
*EditResult*

**Parameters**

- **project** (Project)
- **func** (Function)
- **prototype** (*str* | SimTypeFunction)
- **kb** (KnowledgeBase | *None*)
- **hooks** (EditHooks | *None*)
- **flavor** (*str*)
- **invalidate_cache** (*bool*)
- **preserve_user_edits** (*bool*)
- **redecompile** (*bool*)

angr.analyses.decompiler.edits.**set_global_type**(*project*, *addr*, *c_type*, ***, *kb=None*, *hooks=None*, *flavor=Flavors.DEFAULT_FLAVOR*)

Set the type of a global by address, for the decompilation flavor's view of globals.

**Return type**
*EditResult*

**Parameters**

- **project** (Project)
- **addr** (*int*)

- **c_type** (*str | SimType*)
- **kb** (*KnowledgeBase | None*)
- **hooks** (*EditHooks | None*)
- **flavor** (*str*)

angr.analyses.decompiler.edits.**set_variable_type**(*project*, *func*, *variable_name*, *c_type*, ***, *kb=None*, *hooks=None*, *flavor=Flavors.DEFAULT_FLAVOR*, *reflow=True*, *rerender=True*, *allow_prototype_change=True*, *codegen=None*)

Change the type of a local, an argument, or a global.

Arguments are retyped by rewriting the function prototype, which requires a re-decompilation – the returned Refresh says so. Pass `allow_prototype_change=False` to refuse instead.

**Return type**
*EditResult*

**Parameters**

- **project** (*Project*)
- **func** (*Function*)
- **variable_name** (*str*)
- **c_type** (*str | SimType*)
- **kb** (*KnowledgeBase | None*)
- **hooks** (*EditHooks | None*)
- **flavor** (*str*)
- **reflow** (*bool*)
- **rerender** (*bool*)
- **allow_prototype_change** (*bool*)

angr.analyses.decompiler.edits.**snapshot_user_edits**(*kb*, *func_addr*)

Capture user renames and manual types for a function, keyed by `SimVariable.ident`.

Used to survive the `dec_variables` drop that a prototype change requires.

**Return type**
dict[str, tuple[str | None, *SimType* | None]]

**Parameters**

- **kb** (*KnowledgeBase*)
- **func_addr** (*int*)

angr.analyses.decompiler.edits.**validate_name**(*name*, ***, *strict=True*)

Reject names that cannot be used as identifiers.

`strict` requires a C identifier. Without it only whitespace-free names are required, which still admits things like `int;` that render as uncompilable C – so strict is the default.

**Return type**
None

**Parameters**

- **name** (*str*)
- **strict** (*bool*)

| *results* | |

#### angr.analyses.decompiler.edits.cache

Decompilation-cache access for the edit layer.

Both `kb.decompilations` and `kb.dec_variables` spill to LMDB under memory pressure and hand back a freshly deserialized – that is, *different* – Python object on reload. Never hold a `DecompilationCache` or a `VariableManagerInternal` across anything that can decompile; always re-fetch by key at the point of mutation.

angr.analyses.decompiler.edits.cache.**get_cache**(*kb*, *func_addr*, *flavor=Flavors.DEFAULT_FLAVOR*)

Return the cached decompilation for a function, or None if there is none.

**Return type**
*DecompilationCache* | None

**Parameters**

- **kb** (KnowledgeBase)
- **func_addr** (*int*)
- **flavor** (*str*)

angr.analyses.decompiler.edits.cache.**require_cache**(*kb*, *func_addr*, *flavor=Flavors.DEFAULT_FLAVOR*)

Return the cached decompilation, raising NotDecompiledError if it is missing or empty.

**Return type**
*DecompilationCache*

**Parameters**

- **kb** (KnowledgeBase)
- **func_addr** (*int*)
- **flavor** (*str*)

angr.analyses.decompiler.edits.cache.**invalidate**(*kb*, *func_addr*, ***, *flavors=None*, *drop_variables=False*)

Drop cached decompilations for a function.

**Parameters**

- **flavors** (Iterable[str] | None) – Flavors to drop; None drops every flavor currently cached. A prototype change must drop all of them, or a non-pseudocode flavor silently retains the old signature.
- **drop_variables** (bool) – Also drop `kb.dec_variables[func_addr]`. Required for new argument names to take effect, but it discards every rename and manual type for the function – see *snapshot_user_edits()*.
- **kb** (KnowledgeBase)
- **func_addr** (*int*)

**Return type**
None

angr.analyses.decompiler.edits.cache.**snapshot_user_edits**(*kb*, *func_addr*)

Capture user renames and manual types for a function, keyed by `SimVariable.ident`.

Used to survive the `dec_variables` drop that a prototype change requires.

**Return type**
dict[str, tuple[str | None, *SimType* | None]]

**Parameters**

- **kb** (KnowledgeBase)
- **func_addr** (*int*)

angr.analyses.decompiler.edits.cache.**restore_user_edits**(*kb*, *func_addr*, *snapshot*)

Re-apply a *snapshot_user_edits()* result after re-decompilation.

Best-effort: idents can change across a re-decompile, so the unmatched ones are returned rather than silently dropped.

**Return type**
tuple[int, list[str]]

**Parameters**

- **kb** (KnowledgeBase)
- **func_addr** (*int*)
- **snapshot** (*dict[str, tuple[str | None, SimType | None]]*)

angr.analyses.decompiler.edits.cache.**function_summary**(*kb*, *func_addr*)

Small helper for edit results: what is currently cached for a function.

**Return type**
dict[str, Any]

**Parameters**

- **kb** (KnowledgeBase)
- **func_addr** (*int*)

### angr.analyses.decompiler.edits.errors

**exception** angr.analyses.decompiler.edits.errors.**DecompilationEditError**

Bases: *AngrError*

Base class for every failure raised by the decompilation edit layer.

**exception** angr.analyses.decompiler.edits.errors.**FunctionNotFoundError**

Bases: *DecompilationEditError*

No function matches the given address or name.

**exception** angr.analyses.decompiler.edits.errors.**AmbiguousFunctionError**

Bases: *DecompilationEditError*

More than one function matches the given name. Renames make this reachable.

**exception** angr.analyses.decompiler.edits.errors.**VariableNotFoundError**

Bases: *DecompilationEditError*

No variable in the decompilation matches the given display name.

`candidates` carries the names that *are* available, so a caller that failed can correct itself without a second round trip.

**exception** angr.analyses.decompiler.edits.errors.**NotDecompiledError**

Bases: *DecompilationEditError*

The function has no cached decompilation, so there is nothing to edit.

**exception** angr.analyses.decompiler.edits.errors.**InvalidNameError**

Bases: *DecompilationEditError*

The requested name is not a usable identifier.

**exception** angr.analyses.decompiler.edits.errors.**NameCollisionError**

Bases: *DecompilationEditError*

The requested name is already bound to a different function, variable, or label.

**exception** angr.analyses.decompiler.edits.errors.**TypeParseError**

Bases: *DecompilationEditError*

A C type declaration or function signature could not be parsed.

**exception** angr.analyses.decompiler.edits.errors.**UnsupportedEditError**

Bases: *DecompilationEditError*

The requested edit is not supported for this kind of target.

### angr.analyses.decompiler.edits.hooks

**class** angr.analyses.decompiler.edits.hooks.**EditHooks**

Bases: Protocol

Notifications fired immediately *before* each mutation, while the old value is still readable from the knowledge base.

The method set mirrors angr-management's plugin hooks one-for-one so its adapter is a pure forwarder. Firing before the mutation matches what the GUI's own edit dialogs do, and is what lets a handler snapshot pre-edit state.

**before_function_renamed**(*func*, *old_name*, *new_name*)

**Return type**
None

**Parameters**

- **func** (Function)

- **old_name** (*str*)
- **new_name** (*str*)

**before_stack_var_renamed**(*func*, *offset*, *old_name*, *new_name*)

**Return type**
None

**Parameters**

- **func** (Function)
- **offset** (*int*)
- **old_name** (*str*)
- **new_name** (*str*)

**before_func_arg_renamed**(*func*, *arg_index*, *old_name*, *new_name*)

**Return type**
None

**Parameters**

- **func** (Function)
- **arg_index** (*int*)
- **old_name** (*str*)
- **new_name** (*str*)

**before_global_var_renamed**(*addr*, *old_name*, *new_name*)

**Return type**
None

**Parameters**

- **addr** (*int*)
- **old_name** (*str*)
- **new_name** (*str*)

**before_stack_var_retyped**(*func*, *offset*, *old_type*, *new_type*)

**Return type**
None

**Parameters**

- **func** (Function)
- **offset** (*int*)
- **old_type** (SimType | *None*)
- **new_type** (SimType)

**before_func_arg_retyped**(*func*, *arg_index*, *old_type*, *new_type*)

**Return type**
None

**Parameters**

- **func** (Function)
- **arg_index** (*int*)
- **old_type** (SimType | *None*)
- **new_type** (SimType)

**before_global_var_retyped**(*addr*, *old_type*, *new_type*)

**Return type**
None

**Parameters**

- **addr** (*int*)
- **old_type** (SimType | *None*)
- **new_type** (SimType)

**before_other_var_retyped**(*var*, *old_type*, *new_type*)

**Return type**
None

**Parameters**

- **var** (SimVariable)
- **old_type** (SimType | *None*)
- **new_type** (SimType)

**before_function_retyped**(*func*, *old_proto*, *new_proto*)

**Return type**
None

**Parameters**

- **func** (Function)
- **old_proto** (SimTypeFunction | *None*)
- **new_proto** (SimTypeFunction)

**before_comment_changed**(*addr*, *old*, *new*, *created*, *decomp*)

**Return type**
None

**Parameters**

- **addr** (*int*)
- **old** (*str*)
- **new** (*str*)
- **created** (*bool*)
- **decomp** (*bool*)

**__init__**(**args*, ***kwargs*)

class angr.analyses.decompiler.edits.hooks.**NullEditHooks**

Bases: object

A concrete no-op implementation. Subclass it so an adapter only overrides what it needs.

**before_function_renamed**(*func*, *old_name*, *new_name*)

**Return type**
None

**Parameters**

- **func** (Function)
- **old_name** (*str*)
- **new_name** (*str*)

**before_stack_var_renamed**(*func*, *offset*, *old_name*, *new_name*)

**Return type**
None

**Parameters**

- **func** (Function)
- **offset** (*int*)
- **old_name** (*str*)
- **new_name** (*str*)

**before_func_arg_renamed**(*func*, *arg_index*, *old_name*, *new_name*)

**Return type**
None

**Parameters**

- **func** (Function)
- **arg_index** (*int*)
- **old_name** (*str*)
- **new_name** (*str*)

**before_global_var_renamed**(*addr*, *old_name*, *new_name*)

**Return type**
None

**Parameters**

- **addr** (*int*)
- **old_name** (*str*)
- **new_name** (*str*)

**before_stack_var_retyped**(*func*, *offset*, *old_type*, *new_type*)

**Return type**
None

**Parameters**

- **func** (Function)
- **offset** (*int*)
- **old_type** (SimType | *None*)
- **new_type** (SimType)

**before_func_arg_retyped**(*func*, *arg_index*, *old_type*, *new_type*)

**Return type**
None

**Parameters**

- **func** (Function)
- **arg_index** (*int*)
- **old_type** (SimType | *None*)
- **new_type** (SimType)

**before_global_var_retyped**(*addr*, *old_type*, *new_type*)

**Return type**
None

**Parameters**

- **addr** (*int*)
- **old_type** (SimType | *None*)
- **new_type** (SimType)

**before_other_var_retyped**(*var*, *old_type*, *new_type*)

**Return type**
None

**Parameters**

- **var** (SimVariable)
- **old_type** (SimType | *None*)
- **new_type** (SimType)

**before_function_retyped**(*func*, *old_proto*, *new_proto*)

**Return type**
None

**Parameters**

- **func** (Function)
- **old_proto** (SimTypeFunction | *None*)
- **new_proto** (SimTypeFunction)

**before_comment_changed**(*addr*, *old*, *new*, *created*, *decomp*)

**Return type**
None

**Parameters**

- **addr** (*int*)
- **old** (*str*)
- **new** (*str*)
- **created** (*bool*)
- **decomp** (*bool*)

angr.analyses.decompiler.edits.hooks.**coerce_hooks**(*hooks*)

**Return type**
*EditHooks*

**Parameters**
**hooks** (EditHooks | *None*)

### angr.analyses.decompiler.edits.ops

The mutating operations of the edit layer.

Every operation re-fetches the decompilation cache by key at the point of mutation rather than holding a reference: see the note in *cache*.

angr.analyses.decompiler.edits.ops.**rename_function**(*project*, *func*, *new_name*, ***, *kb=None*, *hooks=None*, *flavor=Flavors.DEFAULT_FLAVOR*, *allow_overwrite=True*, *strict_names=True*, *rerender=True*)

Rename a function.

Nothing is invalidated: other functions' cached ASTs reference the same Function object, so only their rendered text goes stale. That is reported through `Refresh.text_stale_all` for the caller to act on lazily.

**Return type**
*EditResult*

**Parameters**

- **project** (Project)
- **func** (Function)
- **new_name** (*str*)
- **kb** (KnowledgeBase | *None*)
- **hooks** (EditHooks | *None*)
- **flavor** (*str*)
- **allow_overwrite** (*bool*)
- **strict_names** (*bool*)
- **rerender** (*bool*)

angr.analyses.decompiler.edits.ops.**rename_variable**(*project*, *func*, *variable_name*, *new_name*, ***, *kb=None*, *hooks=None*, *flavor=Flavors.DEFAULT_FLAVOR*, *allow_overwrite=True*, *strict_names=True*, *rerender=True*, *codegen=None*)

Rename a local, an argument, or a global as it appears in a function's decompilation.

Sets `renamed` on the variable, without which a later re-decompilation overwrites the name.

**Return type**
*EditResult*

**Parameters**

- **project** (Project)
- **func** (Function)
- **variable_name** (*str*)
- **new_name** (*str*)
- **kb** (KnowledgeBase | *None*)
- **hooks** (EditHooks | *None*)
- **flavor** (*str*)
- **allow_overwrite** (*bool*)
- **strict_names** (*bool*)
- **rerender** (*bool*)

angr.analyses.decompiler.edits.ops.**reflow_types**(*project*, *func*, *, *kb=None*, *flavor=Flavors.DEFAULT_FLAVOR*, *rerender=True*)

Re-run type inference over the cached constraints and refresh the rendered code.

Separate from *set_variable_type()* so a batch can retype many variables and reflow once; per-variable reflow would re-run Typehoon N times.

This is not a re-decompilation: the AST is untouched, so a retype that should change how an access renders (a struct field, an array index) needs a full re-decompilation instead.

**Parameters**

- **project** (Project)
- **func** (Function)
- **kb** (KnowledgeBase | *None*)
- **flavor** (*str*)
- **rerender** (*bool*)

angr.analyses.decompiler.edits.ops.**set_variable_type**(*project*, *func*, *variable_name*, *c_type*, *, *kb=None*, *hooks=None*, *flavor=Flavors.DEFAULT_FLAVOR*, *reflow=True*, *rerender=True*, *allow_prototype_change=True*, *codegen=None*)

Change the type of a local, an argument, or a global.

Arguments are retyped by rewriting the function prototype, which requires a re-decompilation – the returned Refresh says so. Pass `allow_prototype_change=False` to refuse instead.

**Return type**
*EditResult*

**Parameters**

- **project** (Project)
- **func** (Function)
- **variable_name** (*str*)
- **c_type** (*str* | SimType)
- **kb** (KnowledgeBase | *None*)
- **hooks** (EditHooks | *None*)
- **flavor** (*str*)
- **reflow** (*bool*)
- **rerender** (*bool*)
- **allow_prototype_change** (*bool*)

angr.analyses.decompiler.edits.ops.**set_function_prototype**(*project*, *func*, *prototype*, ***, *kb=None*, *hooks=None*, *flavor=Flavors.DEFAULT_FLAVOR*, *invalidate_cache=True*, *preserve_user_edits=True*, *redecompile=False*)

Set a function's prototype.

The function name inside the signature is ignored; use *rename_function()* to rename.

Dropping kb.dec_variables is what makes new argument names take effect, but it also discards every rename and manual type for the function. Those are snapshotted and, when this function re-decompiles, restored. Otherwise the snapshot is returned in `detail["user_edits"]` so a caller that decompiles asynchronously can restore it once its own job finishes.

**Return type**
*EditResult*

**Parameters**

- **project** (Project)
- **func** (Function)
- **prototype** (*str* | SimTypeFunction)
- **kb** (KnowledgeBase | *None*)
- **hooks** (EditHooks | *None*)
- **flavor** (*str*)
- **invalidate_cache** (*bool*)
- **preserve_user_edits** (*bool*)
- **redecompile** (*bool*)

angr.analyses.decompiler.edits.ops.**set_comment**(*project*, *addr*, *comment*, ***, *kind=None*, *kb=None*, *hooks=None*, *flavor=Flavors.DEFAULT_FLAVOR*, *mirror_to_pseudocode=True*, *snap=True*, *rerender=True*)

Set the comment at an address, or clear it with an empty string or None.

The comment goes into kb.comments, which the disassembly renders and which the decompiler reads for the function header. Per-statement pseudocode comments live in codegen.stmt_comments instead, so both are written – except at the function entry, where kb.comments is already what the header renders and mirroring would show the comment twice.

kind sets the comment's display kind; None keeps whatever kind the comment already has. Clearing a comment always clears its kind.

**Return type**
*EditResult*

**Parameters**

- **project** (Project)
- **addr** (*int*)
- **comment** (*str* | *None*)
- **kind** (CommentKind | *None*)
- **kb** (KnowledgeBase | *None*)
- **hooks** (EditHooks | *None*)
- **flavor** (*str*)
- **mirror_to_pseudocode** (*bool*)
- **snap** (*bool*)
- **rerender** (*bool*)

angr.analyses.decompiler.edits.ops.**global_variable_at**(*kb*, *addr*, *flavor=Flavors.DEFAULT_FLAVOR*)

The global SimVariable recorded at an address by a decompilation of the flavor, if there is one.

**Return type**
*SimMemoryVariable* | None

**Parameters**

- **kb** (KnowledgeBase)
- **addr** (*int*)
- **flavor** (*str*)

angr.analyses.decompiler.edits.ops.**rename_global**(*project*, *addr*, *new_name*, ***, *kb=None*, *hooks=None*, *allow_overwrite=True*, *strict_names=True*)

Rename a global by address, without needing a function whose decompilation shows it.

**Return type**
*EditResult*

**Parameters**

- **project** (Project)
- **addr** (*int*)
- **new_name** (*str*)
- **kb** (KnowledgeBase | *None*)

- **hooks** (EditHooks | *None*)
- **allow_overwrite** (*bool*)
- **strict_names** (*bool*)

angr.analyses.decompiler.edits.ops.**set_global_type**(*project*, *addr*, *c_type*, ***, *kb=None*, *hooks=None*, *flavor=Flavors.DEFAULT_FLAVOR*)

Set the type of a global by address, for the decompilation flavor's view of globals.

**Return type**
*EditResult*

**Parameters**

- **project** (Project)
- **addr** (*int*)
- **c_type** (*str* | SimType)
- **kb** (KnowledgeBase | *None*)
- **hooks** (EditHooks | *None*)
- **flavor** (*str*)

### angr.analyses.decompiler.edits.resolve

Resolution helpers shared by every edit operation: address-or-name to Function, and pseudocode display name to the underlying SimVariable.

angr.analyses.decompiler.edits.resolve.**parse_address**(*value*)

Parse an address given as an int or a string. Accepts 0x-prefixed hex and decimal.

**Return type**
int

**Parameters**
**value** (*str* | *int*)

angr.analyses.decompiler.edits.resolve.**validate_name**(*name*, ***, *strict=True*)

Reject names that cannot be used as identifiers.

`strict` requires a C identifier. Without it only whitespace-free names are required, which still admits things like `int;` that render as uncompilable C – so strict is the default.

**Return type**
None

**Parameters**

- **name** (*str*)
- **strict** (*bool*)

angr.analyses.decompiler.edits.resolve.**resolve_function**(*kb*, ***, *address=None*, *name=None*, *containing=True*)

Find a function by address or by name.

**Parameters**

- **containing** (bool) – If True, an address inside a function resolves to that function rather than requiring the exact entry address.

- **kb** (KnowledgeBase)
- **address** (*str | int | None*)
- **name** (*str | None*)

**Return type**
*Function*

**class** angr.analyses.decompiler.edits.resolve.**ResolvedVariable**

Bases: object

A pseudocode display name resolved to the objects an edit needs.

`variable` is the concrete/SSA variable that `set_variable_type` expects; `unified` is the unified variable that a rename mutates (None for globals, which have no unified form).

**kind:** Literal['argument', 'local', 'global']

**variable:** *SimVariable*

**unified:** *SimVariable* | None

**cvar:** *CVariable* | None = None

**arg_index:** int | None = None

**stack_offset:** int | None = None

**global_addr:** int | None = None

**ambiguous:** bool = False

**property name:** str | None

**property storage:** str

**detail**()

**Return type**
dict

**__init__**(*kind*, *variable*, *unified*, *cvar=None*, *arg_index=None*, *stack_offset=None*, *global_addr=None*, *ambiguous=False*)

**Parameters**

- **kind** (*VariableKind*)
- **variable** (SimVariable)
- **unified** (SimVariable | *None*)
- **cvar** (CVariable | *None*)
- **arg_index** (*int | None*)
- **stack_offset** (*int | None*)
- **global_addr** (*int | None*)
- **ambiguous** (*bool*)

**Return type**
None

angr.analyses.decompiler.edits.resolve.**concrete_variables**(*varman*, *resolved*)

Every SSA variable sharing the resolved variable's unified form.

Retyping applies to all of them. Computed here rather than relying on `set_variable_type(all_unified=True)`, which silently does nothing when the variable it is handed is not a key in the SSA-to-unified map.

**Return type**
list[*SimVariable*]

**Parameters**
**resolved** (ResolvedVariable)

angr.analyses.decompiler.edits.resolve.**list_variable_names**(*codegen*, *kb=None*, *func_addr=None*)

Every display name addressable in this decompilation, for error messages.

**Return type**
list[str]

**Parameters**

- **kb** (KnowledgeBase | *None*)
- **func_addr** (*int* | *None*)

angr.analyses.decompiler.edits.resolve.**resolve_variable**(*kb*, *func_addr*, *display_name*, ***, *codegen=None*, *flavor=Flavors.DEFAULT_FLAVOR*)

Resolve a name as it appears in the pseudocode to the underlying variable.

Precedence is argument > local > global. A name matching more than one variable within the same bucket resolves deterministically and sets `ambiguous`, rather than failing – a batch edit should be able to report the collision and continue.

**Return type**
*ResolvedVariable*

**Parameters**

- **kb** (KnowledgeBase)
- **func_addr** (*int*)
- **display_name** (*str*)
- **flavor** (*str*)

### angr.analyses.decompiler.edits.results

**class** angr.analyses.decompiler.edits.results.**Refresh**

Bases: object

What a caller has to redo after an edit.

Lets a UI pick between re-rendering text, rebuilding the codegen AST, and a full re-decompilation instead of guessing. `text_stale_all` means every cached decompilation's rendered text is stale (a function rename changes call sites everywhere), but the caller should re-render lazily: eagerly re-rendering the whole cache would thrash its LRU.

**text_stale: frozenset[int] = frozenset({})**

**text_stale_all: bool = False**

**reanalyze:** frozenset[int] = frozenset({})

**redecompile:** frozenset[int] = frozenset({})

**function_list_dirty:** bool = False

**disassembly_dirty:** bool = False

**merge**(*other*)

**Return type**
*Refresh*

**Parameters**
**other** (Refresh)

**__init__**(*text_stale=frozenset({})*, *text_stale_all=False*, *reanalyze=frozenset({})*, *redecompile=frozenset({})*, *function_list_dirty=False*, *disassembly_dirty=False*)

**Parameters**

- **text_stale** (*frozenset[int]*)
- **text_stale_all** (*bool*)
- **reanalyze** (*frozenset[int]*)
- **redecompile** (*frozenset[int]*)
- **function_list_dirty** (*bool*)
- **disassembly_dirty** (*bool*)

**Return type**
None

**class** angr.analyses.decompiler.edits.results.**EditResult**

Bases: object

The outcome of a single edit. changed is False when the edit was a no-op.

**changed:** bool

**kind:** str

**func_addr:** int | None = None

**old:** Any = None

**new:** Any = None

**refresh:** *Refresh*

**detail:** dict[str, Any]

**__init__**(*changed*, *kind*, *func_addr=None*, *old=None*, *new=None*, *refresh=<factory>*, *detail=<factory>*)

**Parameters**

- **changed** (*bool*)
- **kind** (*str*)
- **func_addr** (*int | None*)

- **old** (*Any*)
- **new** (*Any*)
- **refresh** (Refresh)
- **detail** (*dict[str, Any]*)

**Return type**
None

### angr.analyses.decompiler.empty_node_remover

**class** angr.analyses.decompiler.empty_node_remover.**EmptyNodeRemover**

Bases: object

Rewrites a node and its children to remove empty nodes.

The following optimizations are performed at the same time: - Convert if (A) { } else { ... } to if(!A) { ... } else { }

**Variables**
**_claripy_ast_conditions** – True if all node conditions are claripy ASTs. False if all node conditions are AIL expressions.

**__init__**(*node*, *ail_manager*, *claripy_ast_conditions=True*)

**Parameters**

- **ail_manager** (*Manager*)
- **claripy_ast_conditions** (*bool*)

### angr.analyses.decompiler.expression_narrower

**class** angr.analyses.decompiler.expression_narrower.**ExprNarrowingInfo**

Bases: object

Stores the analysis result of _narrowing_needed().

**__init__**(*narrowable*, *to_size=None*, *use_exprs=None*, *phi_vars=None*, *insert_deps=None*)

**Parameters**

- **narrowable** (*bool*)
- **to_size** (*int | None*)
- **use_exprs** (*list[tuple[VirtualVariable, AILCodeLocation]] | None*)
- **phi_vars** (*set[VirtualVariable] | None*)
- **insert_deps** (*list[tuple[int, int]] | None*)

**narrowable**

**to_size**

**use_exprs**

**phi_vars**

**insert_deps**

class angr.analyses.decompiler.expression_narrower.**EffectiveSizeExtractor**

Bases: *AILBlockWalker*[None, None, None]

Walks a statement once and extracts the effective size (in bits) of every virtual variable that appears in it.

For example, for virtual variable rax, *(rax & 0xff) + 0x1* means the effective size of rax is 8 bits, from bit 0 to bit 7. We record this information in vvar_effective_bits as {rax.varid: {rax.idx: (0, 8)}}.

We pay special consideration to expressions that are used as Call arguments, as they may have been converted to a smaller size because the Call argument needs that size, but the Call prototype may have been incorrectly inferred.

A single walk records information for all virtual variables in the statement, so one walker instance can be queried for many different variables without re-walking the statement. Constraints that parent expressions impose on their children are handed down per visit, not keyed by node `idx`: AIL nodes (and their idx) may be shared between several parents in one statement. Results are aggregated per (varid, expression idx); occurrences that share an idx are merged by taking the union of their bit ranges.

**__init__**(*ignore_call_args=True*)

**Parameters**
**ignore_call_args** (*bool*)

**vvar_effective_bits:** dict[int, dict[int, tuple[int, int]]]

**vvar_call_arg_effective_bits:** dict[int, tuple[int, int]]

**vvars_used_as_insert_base:** set[int]

class angr.analyses.decompiler.expression_narrower.**ExpressionNarrower**

Bases: *AILBlockRewriter*

Narrows an expression regardless of whether the expression is a definition or a use.

**__init__**(*project*, *rd*, *manager*, *narrowables*, *addr2blocks*, *new_blocks*)

**Parameters**

- **manager** (*Manager*)
- **addr2blocks** (*dict[tuple[int, int], Block]*)
- **new_blocks** (*dict[Block, Block]*)

**new_vvar_sizes:** dict[int, int]

**replacement_core_vvars:** dict[int, list[*VirtualVariable*]]

**walk**(*block*)

**Parameters**
**block** (Block)

### angr.analyses.decompiler.goto_manager

class angr.analyses.decompiler.goto_manager.**Goto**

Bases: object

Describe the existence of a goto (jump) statement. May have multiple gotos with the same address (targets will differ).

**__init__**(*src_addr*, *dst_addr*, *src_idx=0*, *dst_idx=0*, *src_ins_addr=None*)

class angr.analyses.decompiler.goto_manager.**GotoManager**

Bases: object

Container class for all Gotos found in a function after decompilation structuring. This should be populated using GotoSimplifier.

**__init__**(*func*, *gotos=None*)

**gotos_in_block**(*block*)

**Return type**
set[*Goto*]

**Parameters**
**block** (*Block*)

**is_goto_edge**(*src*, *dst*)

**Parameters**

- **src** (*Block*)
- **dst** (*Block*)

**find_goto_edges**(*graph*)

This function finds all edges that are _potential_ gotos in the graph. The gotos are not guaranteed to be correct, but they are an approximation based on how the Phoenix structuring algorithm will select edges from the graph to be gotos in structuring.

**Return type**
list[tuple[Block, Block]]

**Parameters**
**graph** (*DiGraph*)

### angr.analyses.decompiler.ireg_resolver

class angr.analyses.decompiler.ireg_resolver.**IRegisterResolver**

Bases: object

Resolves `IRegister` (VEX GetI/PutI register-array accesses, e.g. x87 `fpreg[ftop]`) into concrete `Register` expressions by forward-tracking constant register values across the AIL graph.

The x87 stack pointer `ftop` is 0 at the function entry (the ABI requires an empty x87 stack across calls). At a call site the callee's net effect on `ftop` is derived from, in order, the callee's own code, its prototype, and the first x87 stack access that follows the call in the caller. Blocks whose entry `ftop` cannot be determined exactly (conflicting predecessors, e.g. an unbalanced path) fall back to the most common value among their predecessors, so that every x87 access still resolves to a concrete `st(i)`. Reads of `ftop` outside of register-array indices (`fnstsw`) are replaced with the tracked constant. `fptan`'s conditional push (`ftop - 1Uto32(in_range)`) is treated as unconditional.

**__init__**(*project*, *kb*, *function*, *ail_graph*, *callee_deltas=None*, *call_st0=None*, *call_ftop=None*)

**Parameters**

- **project** (Project)
- **kb** (KnowledgeBase)
- **function** (Function)
- **ail_graph** (*networkx.DiGraph*)

- **callee_deltas** (*dict[int, int | None] | None*)
- **call_st0** (*dict[int, int] | None*)
- **call_ftop** (*dict[int, int] | None*)

**static has_iregisters**(*ail_graph*)

**Return type**
bool

**Parameters**
**ail_graph** (*DiGraph*)

**resolve**()

**Return type**
None

### angr.analyses.decompiler.jump_target_collector

**class** angr.analyses.decompiler.jump_target_collector.**JumpTargetCollector**

Bases: object

Collect all jump targets.

**__init__**(*node*)

### angr.analyses.decompiler.jumptable_entry_condition_rewriter

**class** angr.analyses.decompiler.jumptable_entry_condition_rewriter.**JumpTableEntryConditionRewriter**

Bases: *SequenceWalker*

Remove artificial jump table entry conditions that ConditionProcessor introduced when dealing with jump tables.

**__init__**(*jumptable_entry_conds*)

### angr.analyses.decompiler.known_patterns

Known code patterns: context-aware, declarative descriptions of library/macro idioms that compilers inline, plus machinery (KnownPatternFinder) to find them in Clinic AIL graphs and outline them back into calls.

Each idiom is defined once as a `KnownPatternTemplate` that instantiates itself into a concrete `KnownPattern` for the target's `PatternContext` (architecture / platform / C++ runtime), so a single definition covers 32- and 64-bit, libstdc++ and MSVC, etc.

**class** angr.analyses.decompiler.known_patterns.**PITE**

Bases: *PatternExpr*

Matches an ITE (ternary) expression `cond ? iftrue : iffalse`.

Needed because ITERegionConverter (AFTER_GLOBAL_SIMPLIFICATION) collapses `if (c) x = a; else x = b;` diamonds into a single ITE assignment before the KnownPatternOutliner runs, so a two-armed value-select idiom reaches the outliner as an expression, not as a PGraphPat region. (A triangle, with one arm empty as in the MSVC std::string::c_str SSO select, is not converted, which is why that idiom is still a PGraphPat.)

**cond:** *PatternExpr*

**iftrue:** *PatternExpr*

**iffalse:** *PatternExpr*

**name:** str | None = None

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*cond*, *iftrue*, *iffalse*, *name=None*)

**Parameters**

- **cond** (PatternExpr)
- **iftrue** (PatternExpr)
- **iffalse** (PatternExpr)
- **name** (*str | None*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.**AllOf**

Bases: *PatternGate*

Opens when every sub-gate opens.

**gates:** tuple[*PatternGate*, ...]

**opens**(*gctx*)

**Return type**
bool

**Parameters**
**gctx** (GateContext)

**property requires_evidence:** bool

Whether this gate can only be decided once the function's matches are known. Such gates are evaluated a second time by the finder.

**property label:** str

**__init__**(*gates=<factory>*)

**Parameters**
**gates** (*tuple[PatternGate, ...]*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.**AnyOf**

Bases: *PatternGate*

Opens when any sub-gate opens.

**gates:** tuple[*PatternGate*, ...]

**opens**(*gctx*)

**Return type**
bool

**Parameters**
**gctx** (GateContext)

**property requires_evidence:** bool

Whether this gate can only be decided once the function's matches are known. Such gates are evaluated a second time by the finder.

**property label:** str

**__init__**(*gates=<factory>*)

**Parameters**
**gates** (*tuple[PatternGate, ...]*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.**CorroboratedBy**

Bases: *PatternGate*

Opens in a function where at least one of `witnesses` already matched.

Witnesses are given as template `name` or `call_name` values; the finder puts both spellings of every established pattern into the evidence set.

**witnesses:** frozenset[str]

**opens**(*gctx*)

**Return type**
bool

**Parameters**
**gctx** (GateContext)

**property requires_evidence:** bool

Whether this gate can only be decided once the function's matches are known. Such gates are evaluated a second time by the finder.

**property label:** str

**__init__**(*witnesses*)

**Parameters**
**witnesses** (*frozenset[str]*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.**CppRef**

Bases: object

A reference to a C++ class type registered in the cpp::std SimTypeCollection, keyed by its unique (mangled-style) name.

**unique_name:** str

**ptr:** bool = True

**resolve**(*arch*)

**Return type**
*SimType* | None

**Parameters**
**arch** (*archinfo.Arch*)

**__init__**(*unique_name*, *ptr=True*)

**Parameters**

- **unique_name** (*str*)
- **ptr** (*bool*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.**GateContext**

Bases: object

Everything a gate may look at.

**Variables**

- **ctx** (*PatternContext*) – The target's *PatternContext* (arch, platform, C++ runtime, and the binary-evidence facts).
- **project** (*Project* | None) – The Project, for gates that need to look past the context.
- **evidence** (frozenset[str]) – Names and call names of the patterns established in the function currently being matched: both the patterns that matched in the first stage and the known-pattern calls already present in the graph (outlined by an earlier round). Empty when gates are evaluated outside a function.

**ctx:** *PatternContext*

**project:** *Project* | None = None

**evidence:** frozenset[str] = frozenset({})

**with_evidence**(*evidence*)

**Return type**
*GateContext*

**Parameters**
**evidence** (*Iterable[str]*)

__init__(*ctx*, *project=None*, *evidence=frozenset({})*)

**Parameters**

- **ctx** (PatternContext)
- **project** (Project | *None*)
- **evidence** (*frozenset[str]*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.**KnownPattern**

Bases: object

A known code idiom, described declaratively.

**Variables**

- **name** (str) – Identifier, e.g. "std_string_length".
- **display_name** (str) – Human-readable name, e.g. "std::string::length".
- **call_name** (str) – Target name of the synthesized Call.
- **pattern** (*PatternExpr* | *PatternStmt* | *PGraphPat*) – The structural pattern to match.
- **params** (tuple[*PatternParam*, ...]) – Ordered parameters; their captures become the call arguments, in order.
- **returnty** (str | *CppRef* | None) – Return type of the synthesized call.
- **returnty_factory** (Callable[[Arch, dict[str, int]], *SimType* | None] | None) – Optional callable building a call-site-specific return type from the values of the constant extra_args captures (e.g. CONTAINING_RECORD returns a pointer to a record whose layout depends on the matched field offset). Falls back to returnty when it returns None or when the constant values are unavailable.
- **extra_args** (tuple[str, ...]) – Names of (typically constant) captures appended to the call arguments after params.
- **arches** (tuple[str, ...] | None) – Allowed archinfo.Arch.name values; None = any.
- **platforms** (tuple[str, ...] | None) – Allowed OS names (project.simos.name, lowercased); None = any.
- **where** (Callable[[dict[str, *Expression*]], bool] | None) – Optional cross-capture predicate evaluated on the bindings after a structural match.
- **collapse_capture** (str | None) – Optional capture name identifying the idiom that a match belongs to: within one function, matches binding it to the same virtual variable all describe *one* source-level idiom, and only the one with the largest collapse_max_capture constant is kept. The compiler folds CONTAINING_RECORD's subtraction into every field displacement, so one source idiom otherwise emits a call per field, each naming a different (and mostly wrong) record base.
- **collapse_max_capture** (str | None) – Capture whose constant value orders the collapsing; required when collapse_capture is set.
- **binary_guard** (Callable[[*Project*], bool] | None) – Optional predicate on the Project; the pattern is only used when it returns True (e.g. require C++ evidence for STL patterns to avoid false positives on plain C binaries).

- **default_enabled** (bool) – Whether the pattern is used when the caller does not explicitly select patterns. Generic patterns prone to false positives should set this False.

**name:** str

**display_name:** str

**call_name:** str

**pattern:** *PatternExpr* | *PatternStmt* | *PGraphPat*

**params:** tuple[*PatternParam*, ...]

**returnty:** str | *CppRef* | None = None

**returnty_factory:** Callable[[Arch, dict[str, int]], *SimType* | None] | None = None

**extra_args:** tuple[str, ...] = ()

**arches:** tuple[str, ...] | None = None

**platforms:** tuple[str, ...] | None = None

**where:** Callable[[dict[str, *Expression*]], bool] | None = None

**collapse_capture:** str | None = None

**collapse_max_capture:** str | None = None

**binary_guard:** Callable[[*Project*], bool] | None = None

**default_enabled:** bool = True

**suppressed_by:** tuple[str, str, str] | None = None

Drop a match of this pattern when a pattern whose name matches the regex matched on the same object: `(name regex, my capture, their capture)`. The two captures must bind `.likes()`-equal expressions. This is how a generic accessor yields to a specific one on the same base: a bare `Load(s + 8)` is std::string::length on a string and _M_finish on a vector, and the vector's other fields say which. Judged against every match of the suppressing family, selected or not, so it cannot interact with largest-match selection.

**claims_only:** bool = False

Match only to claim a base for `suppressed_by` purposes; never outlined, never rewritten, never reported. For shapes that identify an object beyond doubt but are not worth naming: a vector's capacity check says "this is a vector" and nothing a reader wants a call for.

**pure_calls:** frozenset[str] = frozenset({})

Callees this pattern reads through *PCallResult* whose only effect is their result: once the pattern has consumed that result and nothing else does, the call goes too. Naming a callee in a pattern is already a claim about what it computes; this is the claim that it computes nothing else. `__ctype_b_loc` returns a table pointer, and a bare `__ctype_b_loc();` left behind after `isspace(c)` is noise.

**applicable**(*arch_name*, *platform*)

**Return type**
bool

**Parameters**

- **arch_name** (*str*)

- **platform** (*str | None*)

**const_args_of_call**(*call*)

Recover the `extra_args` constant values from a synthesized call's trailing arguments. Returns None when the call does not carry them.

**Return type**
dict[str, int] | None

**Parameters**
**call** (Call)

**prototype**(*arch*, *const_args=None*)

Build the synthesized call's prototype. `const_args` (the values of the constant `extra_args` captures, see `const_args_of_call()`) enables call-site-specific return types via `returnty_factory`. Returns None if any declared type fails to resolve.

**Return type**
*SimTypeFunction* | None

**Parameters**

- **arch** (*archinfo.Arch*)
- **const_args** (*dict[str, int] | None*)

**__init__**(*name*, *display_name*, *call_name*, *pattern*, *params*, *returnty=None*, *returnty_factory=None*, *extra_args=()*, *arches=None*, *platforms=None*, *where=None*, *collapse_capture=None*, *collapse_max_capture=None*, *binary_guard=None*, *default_enabled=True*, *suppressed_by=None*, *claims_only=False*, *pure_calls=frozenset({})*)

**Parameters**

- **name** (*str*)
- **display_name** (*str*)
- **call_name** (*str*)
- **pattern** (PatternExpr | PatternStmt | PGraphPat)
- **params** (*tuple[PatternParam, ...]*)
- **returnty** (TypeRef | *None*)
- **returnty_factory** (Callable[[*archinfo.Arch*, *dict[str, int]*], SimType | *None*] | *None*)
- **extra_args** (*tuple[str, ...]*)
- **arches** (*tuple[str, ...] | None*)
- **platforms** (*tuple[str, ...] | None*)
- **where** (Callable[[*dict[str, Expression]*], *bool*] | *None*)
- **collapse_capture** (*str | None*)
- **collapse_max_capture** (*str | None*)
- **binary_guard** (Callable[[Project], *bool*] | *None*)
- **default_enabled** (*bool*)
- **suppressed_by** (*tuple[str, str, str] | None*)
- **claims_only** (*bool*)

- **pure_calls** (*frozenset[str]*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.**KnownPatternFinder**

Bases: *Analysis*

Finds occurrences of KnownPatterns in a Clinic AIL graph.

The graph to match on is the final (SSA-form) Clinic graph, i.e. `decompiler.ail_graph` / `clinic.cc_graph`. Matches are reported in `self.matches`; `outline()` turns a match into a synthesized call by invoking the Outliner analysis on a copy of the graph.

**MAX_REMOTE_CHASE_DEPTH = 6**

**__init__**(*func*, *ail_graph*, *patterns=None*, *chase_defs=True*, *chase_remote_defs=True*, *skip_conversions=True*, *vvar_id_start=48879*, *block_addr_start=2864381952*, *ail_manager=None*, *force_patterns=None*)

`patterns` may be pattern templates (KnownPatternTemplate) and/or already-concrete KnownPatterns; templates are instantiated for this binary's PatternContext. When None, the registry is used, filtered down to the templates that are enabled for this target: default-on ones, ones named by `force_patterns`, and ones whose gate opens (see *gating*).

`force_patterns` is the user's force-enable selection, `"all"` or an iterable of template names / call names, and is only consulted when `patterns` is None (an explicit pattern list is already a selection).

**Parameters**

- **func** (Function)
- **ail_graph** (*DiGraph*)
- **patterns** (*Iterable[object] | None*)
- **chase_defs** (*bool*)
- **chase_remote_defs** (*bool*)
- **skip_conversions** (*bool*)
- **vvar_id_start** (*int*)
- **block_addr_start** (*int*)
- **force_patterns** (*str | Iterable[str] | None*)

**matches: list[*KnownPatternMatch*]**

**call_target_names**(*call*)

Public face of `_resolve_call_target()`, for the outliner's clean-up of calls a pattern declared pure.

**Return type**
frozenset[str]

**Parameters**
**call** (Call)

**apply_matches**(*matches*, *ail_graph*)

Apply as many of `matches` as possible, batching where it matters.

Applying one match at a time is fine until several of them interleave in one block, which is exactly what consecutive field swaps do:

**t1 = x->b; t2 = y->b; y->b = t1; x->b = t2;**
^ the next field's load sits in this one's gap

Rewrite the first and the second's statements have moved; rewrite it anyway and the third now has an opaque call sitting in its gap, which no disjointness test will let it move across. So the void statement-span matches of a block, which the finder has already checked do not conflict, are spliced in together, against the statement indices they were found at. Everything else keeps the one-at-a-time path.

Returns the new graph and the ids of the matches that were applied.

**Return type**
tuple[DiGraph, set[int]]

**Parameters**

- **matches** (*list[KnownPatternMatch]*)
- **ail_graph** (*DiGraph*)

**outline**(*match*, *ail_graph=None*)

Outline one match: split the anchor block so the matched span forms its own block, invoke the Outliner analysis on it, and rewrite the synthesized callsite into the pattern's call. Operates on (and returns) a copy; neither `self._graph` nor `ail_graph` is mutated.

**Return type**
*OutlineResult*

**Parameters**

- **match** (KnownPatternMatch)
- **ail_graph** (*DiGraph | None*)

**MAX_LIFTED_EXPR_NODES = 8**

Node budget for a lifted parameter expression; see _is_liftable.

**outline_at**(*location*, *pattern*, *ail_graph*)

Find `pattern` at `location` (`(block_addr, block_idx)` or `(block_addr, block_idx, stmt_idx)`) in `ail_graph` and outline it.

**Return type**
*OutlineResult*

**Parameters**

- **location** (*tuple[int, int] | tuple[int, int | None, int]*)
- **pattern** (KnownPattern)
- **ail_graph** (*DiGraph*)

**class** angr.analyses.decompiler.known_patterns.**KnownPatternMatch**

Bases: object

One occurrence of a KnownPattern in an AIL graph.

For expression-level matches, the boundary is `consumed_stmt_idxs` (statements wholly owned by the match, e.g. chased definitions) plus `expr_path` (the location of the matched sub-expression inside the anchor statement). For statement-sequence matches, `stmt_span` holds the ordered matched statement indices (the anchor is the first) and `matched_expr` is None.

`duplicated_stmt_idxs` holds chased definitions that are copied into the outlined region instead of moved: the originals stay where they are (other code still uses them) and the copies make the pattern's captured values the region's live-ins. It is always disjoint from `consumed_stmt_idxs`.

`recomputed_defs` does the same for definitions that live in *another* block (a CSE'd value, possibly reaching the anchor through a phi): the expression is pure, so the region recomputes it from the captured operands.

**pattern:** *KnownPattern*

**block_loc:** tuple[int, int]

**anchor_stmt_idx:** int

**expr_path:** tuple[tuple[str, int | None], ...]

**consumed_stmt_idxs:** frozenset[int]

**captures:** dict[str, *Expression*]

**matched_expr:** *Expression* | None

**duplicated_stmt_idxs:** frozenset[int] = frozenset({})

**recomputed_defs:** tuple[tuple[int, *Expression*], ...] = ()

**base_aliases:** tuple[tuple[int, int, int], ...] = ()

**stmt_span:** tuple[int, ...] | None = None

**block_map:** dict[str, tuple[int, int]] | None = None

**consumed_by_block:** dict[tuple[int, int], frozenset[int]] | None = None

**frontier_locs:** frozenset[tuple[int, int]] | None = None

**__init__**(*pattern*, *block_loc*, *anchor_stmt_idx*, *expr_path*, *consumed_stmt_idxs*, *captures*, *matched_expr*, *duplicated_stmt_idxs=frozenset({})*, *recomputed_defs=()*, *base_aliases=()*, *stmt_span=None*, *block_map=None*, *consumed_by_block=None*, *frontier_locs=None*)

**Parameters**

- **pattern** (KnownPattern)
- **block_loc** (*tuple[int, int]*)
- **anchor_stmt_idx** (*int*)
- **expr_path** (*tuple[tuple[str, int | None], ...]*)
- **consumed_stmt_idxs** (*frozenset[int]*)
- **captures** (*dict[str, Expression]*)
- **matched_expr** (*Expression | None*)
- **duplicated_stmt_idxs** (*frozenset[int]*)
- **recomputed_defs** (*tuple[tuple[int, Expression], ...]*)
- **base_aliases** (*tuple[tuple[int, int, int], ...]*)
- **stmt_span** (*tuple[int, ...] | None*)
- **block_map** (*dict[str, tuple[int, int]] | None*)
- **consumed_by_block** (*dict[tuple[int, int], frozenset[int]] | None*)
- **frontier_locs** (*frozenset[tuple[int, int]] | None*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.**KnownPatternTemplate**

Bases: object

A context-aware pattern definition.

**Variables**

- **call_name** (str) – The synthesized call name (unique across templates).
- **build** (Callable[[*PatternContext*], *KnownPattern* | None]) – build(ctx) -> KnownPattern | None; emits the concrete pattern for ctx (None if it cannot).
- **arches** (frozenset[str] | None) – Allowed Arch.name values; None = any.
- **languages** (frozenset[str] | None) – Allowed languages ({"c","cpp"}); None = any.
- **runtimes** (frozenset[str] | None) – Allowed C++ runtimes ({"libstdcxx","msvc"}); None = any.
- **platforms** (frozenset[str] | None) – Allowed platforms ({"linux","windows"}); None = any.
- **default_enabled** (bool) – Whether the template is used when the caller does not explicitly select patterns.
- **gate** – Optional *PatternGate* that turns an opt-in template on for targets (or functions) where the evidence says the idiom is real; see *gating*. A gate can only open a template, never close a default-on one.

**call_name:** str

**build:** Callable[[*PatternContext*], *KnownPattern* | None]

**arches:** frozenset[str] | None = None

**languages:** frozenset[str] | None = None

**runtimes:** frozenset[str] | None = None

**platforms:** frozenset[str] | None = None

**default_enabled:** bool = False

**name:** str = ''

**gate:** *PatternGate* | None = None

**enabled_for**(*gate_ctx*)

**Return type**
bool

**Parameters**
**gate_ctx** (GateContext)

**applicable**(*ctx*)

**Return type**
bool

**Parameters**
**ctx** (PatternContext)

**instantiate**(*ctx*)

The concrete pattern for `ctx`, or None if this template does not apply there. Memoized: a KnownPattern is a frozen tree that depends on nothing but the context, and callers treat it read-only.

**Return type**
*KnownPattern* | None

**Parameters**
**ctx** (PatternContext)

**__init__**(*call_name*, *build*, *arches=None*, *languages=None*, *runtimes=None*, *platforms=None*, *default_enabled=False*, *name=''*, *gate=None*, *_cache=<factory>*)

**Parameters**

- **call_name** (*str*)
- **build** (*Callable[[PatternContext], KnownPattern | None]*)
- **arches** (*frozenset[str] | None*)
- **languages** (*frozenset[str] | None*)
- **runtimes** (*frozenset[str] | None*)
- **platforms** (*frozenset[str] | None*)
- **default_enabled** (*bool*)
- **name** (*str*)
- **gate** (*PatternGate | None*)
- **_cache** (*dict*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.**OutlineResult**

Bases: object

The outcome of outlining one KnownPatternMatch.

**graph:** DiGraph

**match:** *KnownPatternMatch*

**call_stmt:** *Statement*

**child_func:** *Function* | None

**child_graph:** DiGraph | None

**child_funcargs:** list[*VirtualVariable*]

**__init__**(*graph*, *match*, *call_stmt*, *child_func*, *child_graph*, *child_funcargs*)

**Parameters**

- **graph** (*DiGraph*)
- **match** (KnownPatternMatch)

- **call_stmt** (Statement)
- **child_func** (Function | None)
- **child_graph** (DiGraph | None)
- **child_funcargs** (list[VirtualVariable])

**Return type**
None

class angr.analyses.decompiler.known_patterns.**PAny**

Bases: PatternExpr

Matches any expression.

**name:** str | None = None

**bits:** int | None = None

**match**(*expr*, *state*, *ctx*)

**Return type**
MatchState | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*name=None*, *bits=None*)

**Parameters**

- **name** (str | None)
- **bits** (int | None)

**Return type**
None

class angr.analyses.decompiler.known_patterns.**PAnyStmt**

Bases: PatternStmt

Matches any single statement. The statement-level counterpart of PAny: a placeholder for "something happens here" whose exact form the pattern does not care about.

**optional:** bool = False

**weight:** float = 1.0

**match**(*stmt*, *state*, *ctx*)

**Return type**
MatchState | None

**Parameters**

- **stmt** (Statement)
- **state** (MatchState)
- **ctx** (MatchCtx)

__init__(*, optional=False, weight=1.0)

**Parameters**

- **optional** (*bool*)
- **weight** (*float*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.**PAssign**

Bases: *PatternStmt*

Matches an Assignment statement.

**dst:** *PatternExpr*

**src:** *PatternExpr*

**optional:** bool = False

the statement may be absent from an occurrence

**Type**
fuzzy matching only

**weight:** float = 1.0

relative contribution to an occurrence's score

**Type**
fuzzy matching only

**match**(*stmt*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **stmt** (Statement)
- **state** (MatchState)
- **ctx** (MatchCtx)

__init__(*dst*, *src*, *, *optional=False*, *weight=1.0*)

**Parameters**

- **dst** (PatternExpr)
- **src** (PatternExpr)
- **optional** (*bool*)
- **weight** (*float*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.**PBinOp**

Bases: *PatternExpr*

Matches a BinaryOp. op may be a single op string or a set of acceptable ops. Commutative ops try both operand orders unless commutative is explicitly False.

**op:** *str | frozenset[str]*

**operands:** *tuple[PatternExpr, PatternExpr]*

**commutative:** *bool | None = None*

**name:** *str | None = None*

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*op*, *operands*, *commutative=None*, *name=None*)

**Parameters**

- **op** (*str | frozenset[str]*)
- **operands** (*tuple[PatternExpr, PatternExpr]*)
- **commutative** (*bool | None*)
- **name** (*str | None*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.**PBlockPat**

Bases: *PatternNode*

A labeled block of statements in a multi-block pattern graph. An empty `stmts` sequence matches any block (structure alone identifies it).

**label:** *str*

**stmts:** *PStmtSeq*

**__init__**(*label*, *stmts*)

**Parameters**

- **label** (*str*)
- **stmts** (PStmtSeq)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.**PCall**

Bases: *PatternExpr*

Matches a `Call` whose callee is one of `names`.

The callee is what makes a pattern containing this node self-guarding: an idiom spelled around a named runtime function (`operator delete` in the std::string destructor, `__ctype_b_loc` in `isspace`) cannot be confused with arithmetic that happens to look alike, because no other code calls that function to do something else.

names is matched against every spelling the callee is known by (the raw symbol and its demangled form), so a pattern may name either. Prefer the mangled spelling: it is exact, while a demangled one carries the argument list and varies with the demangler.

args=None leaves the arguments unconstrained; a tuple constrains them positionally, with None in a slot meaning "any expression".

**names:** frozenset[str]

**args:** tuple[*PatternExpr* | None, ...] | None = None

**name:** str | None = None

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*names*, *args=None*, *name=None*)

**Parameters**

- **names** (*frozenset[str]*)
- **args** (*tuple[PatternExpr | None, ...] | None*)
- **name** (*str | None*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.**PCallResult**

Bases: *PatternExpr*

The value a call to one of names returned.

A call's result is rarely used where it is produced: the compiler assigns it to a register and reads that register, often in another block. __ctype_b_loc() is called once per function and its table indexed at every predicate. So this node matches the virtual variable and looks up its definition read-only. Nothing is consumed, moved or recomputed; the call stays where the compiler put it.

An inline Call expression is matched too, for the case where the value is used at its definition.

**names:** frozenset[str]

**name:** str | None = None

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)

- **ctx** (MatchCtx)

**__init__**(*names*, *name=None*)

**Parameters**

- **names** (*frozenset[str]*)
- **name** (*str | None*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.**PCallStmt**

Bases: *PatternStmt*

Matches a statement whose effect is a call.

Ailment has no Call statement: a call whose result is discarded is a `SideEffectStatement` wrapping the Call expression, and one whose result is kept is an ordinary `Assignment`. Both spellings are the same idiom, so both match; `dst`, when given, also constrains the assigned destination, which requires the assignment form.

**call:** *PCall*

**dst:** *PatternExpr* | None = None

**optional:** bool = False

the statement may be absent from an occurrence

**Type**
fuzzy matching only

**weight:** float = 1.0

relative contribution to an occurrence's score

**Type**
fuzzy matching only

**match**(*stmt*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **stmt** (Statement)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*call*, *dst=None*, ***, *optional=False*, *weight=1.0*)

**Parameters**

- **call** (PCall)
- **dst** (PatternExpr | *None*)
- **optional** (*bool*)
- **weight** (*float*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.**PChoice**

Bases: *PatternExpr*

Ordered alternation: matches the first alternative that succeeds.

**alternatives:** tuple[*PatternExpr*, ...]

**__init__**(**alternatives*)

**Parameters**
**alternatives** (PatternExpr)

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

class angr.analyses.decompiler.known_patterns.**PCondJump**

Bases: *PatternStmt*

Matches a ConditionalJump, matching its condition expression.

**condition:** *PatternExpr*

**optional:** bool = False

the statement may be absent from an occurrence

**Type**
fuzzy matching only

**weight:** float = 1.0

relative contribution to an occurrence's score

**Type**
fuzzy matching only

**match**(*stmt*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **stmt** (Statement)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*condition*, ***, *optional=False*, *weight=1.0*)

**Parameters**

- **condition** (PatternExpr)
- **optional** (*bool*)
- **weight** (*float*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.**PConst**

Bases: *PatternExpr*

Matches a Const, by exact value or by predicate. Width is ignored unless `bits` is given (e.g. shift amounts are often 8-bit).

**value:** `int | None = None`

**pred:** `Callable[[int], bool] | None = None`

**bits:** `int | None = None`

**name:** `str | None = None`

**values:** `frozenset[int] | None = None`

an enumerable set of acceptable values. Prefer this over `pred` when the set is known: the finder indexes patterns by the constants they accept, so a pattern is only tried where one of its constants occurs.

**symbol:** `str | None = None`

the address of this symbol in the binary being matched, resolved through `MatchCtx.symbol_addr_fn`; the portable spelling of a global's address

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*value=None*, *pred=None*, *bits=None*, *name=None*, *values=None*, *symbol=None*)

**Parameters**

- **value** (*int | None*)
- **pred** (*Callable[[int], bool] | None*)
- **bits** (*int | None*)
- **name** (*str | None*)
- **values** (*frozenset[int] | None*)
- **symbol** (*str | None*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.**PConv**

Bases: *PatternExpr*

Matches a Convert explicitly (never skipped).

**operand:** *PatternExpr*

**from_bits:** int | None = None

**to_bits:** int | None = None

**name:** str | None = None

**match**(*expr*, *state*, *ctx*)

**Return type**
MatchState | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*operand*, *from_bits=None*, *to_bits=None*, *name=None*)

**Parameters**

- **operand** (PatternExpr)
- **from_bits** (*int | None*)
- **to_bits** (*int | None*)
- **name** (*str | None*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.**PDefOf**

Bases: *PatternExpr*

`inner`, or a virtual variable whose reaching definition is `inner`.

The compiler is free to compute a value once and use it twice, and it does so exactly where an idiom uses one value twice. `if (_M_p != &_M_local_buf) operator delete(_M_p, ...)` reads _M_p in the compare and in the call, so gcc loads it into a register and the pattern sees `Load(s)` in neither place; it sees the same virtual variable in both.

Reading that variable's definition is read-only. Nothing is consumed, moved or recomputed, and the identification stays accurate even if memory changes afterwards: the variable holds what the load produced at the definition, which is what the idiom meant. That is why this is not `peek_fn`, whose contract ("can be recomputed at the use") a load cannot satisfy.

The unconsumed definition is left where it was, so a region that matches through this node keeps it as residue. That is harmless, and dead-code elimination removes it once the idiom's other uses are gone.

**inner:** *PatternExpr*

**name:** str | None = None

**match**(*expr*, *state*, *ctx*)

**Return type**
MatchState | None

**Parameters**

- **expr** (Expression)

- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*inner*, *name=None*)

**Parameters**

- **inner** (PatternExpr)
- **name** (*str | None*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.**PExtract**

Bases: *PatternExpr*

Matches an `Extract`, a bit-slice of a wider value.

This is how a scalar reaches integer code out of a vector register when the 128-bit op did not get narrowed away: `movq %xmm2,%rax` on a value that came from `maxsd`/`mulsd` lifts to `Extract(vvar_128, 64bits@0)` rather than to a Convert. Without a node for it, every libm bit-twiddle whose operand is a computed double rather than an incoming argument is unmatchable.

`bits`/`offset` default to unconstrained; `offset` is in bits.

**operand:** *PatternExpr*

**bits:** int | None = None

**offset:** int | None = None

**name:** str | None = None

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*operand*, *bits=None*, *offset=None*, *name=None*)

**Parameters**

- **operand** (PatternExpr)
- **bits** (*int | None*)
- **offset** (*int | None*)
- **name** (*str | None*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.**PField**

Bases: *PatternExpr*

The *address* of the field at `offset` inside the object bound to `base`.

Spelling a container's fields as `PLoad(PVVar("v"))` / `PLoad(PVVar("v") + 8)` requires the object to sit at the very address held in a virtual variable. That is the minority case: measured over the benchmark corpus, only 10-25% of the DWARF sites for a `std::vector` accessor read the container through a bare pointer; the rest reach it as a *field of something else* (`this->tokens.size()`), which lifts to `Load(this + 56)` / `Load(this + 64)` and cannot bind `v` at all.

`PField` matches such an address and binds `base` to the object's own address: `root` when the object is at offset 0, else `root + K`. Two fields of one object therefore unify on `K`, which is what keeps the node honest: it replaces the constraint "this displacement is exactly 8" with "these two displacements differ by exactly 8".

Only use it in patterns that reference at least two fields. With a single field there is no second displacement to constrain, so `PLoad(PField("s", 8))` degenerates into "any load through a pointer plus a non-negative constant" and matches essentially everything.

`root` must be a virtual variable: the outliner materializes `tmp = root + K` ahead of the region so the synthesized call still takes a variable.

**base:** *str*

**offset:** *int*

**name:** *str | None* = **None**

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (*Expression*)
- **state** (*MatchState*)
- **ctx** (*MatchCtx*)

**__init__**(*base*, *offset*, *name=None*)

**Parameters**

- **base** (*str*)
- **offset** (*int*)
- **name** (*str | None*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.**PGraphPat**

Bases: *PatternNode*

A multi-block pattern: labeled blocks connected by edges.

`blocks` maps a label to its `PBlockPat`. `edges` are `(src_label, dst_label)` pairs; a destination label that does not appear in `blocks` denotes an external successor, a region exit that becomes the Outliner frontier. `entry` is the label of the single entry block. Captures unify across all blocks (one bindings environment).

**blocks:** dict[str, *PBlockPat*]

**edges:** Sequence[tuple[str, str]]

**entry:** str

**property external_labels:** set[str]

**__init__**(*blocks*, *edges*, *entry*)

**Parameters**

- **blocks** (*dict[str, PBlockPat]*)
- **edges** (*Sequence[tuple[str, str]]*)
- **entry** (*str*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.**PLoad**

Bases: *PatternExpr*

Matches a memory Load. `size` is in bytes.

**addr:** *PatternExpr*

**size:** int | None = None

**name:** str | None = None

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*addr*, *size=None*, *name=None*)

**Parameters**

- **addr** (PatternExpr)
- **size** (*int | None*)
- **name** (*str | None*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.**PPhi**

Bases: *PatternExpr*

Matches a Phi expression, capturing it whole (its individual sources are not matched). Useful for loop-header blocks, whose statements are phi assignments.

**name:** str | None = None

**bits:** int | None = None

**match**(*expr*, *state*, *ctx*)

**Return type**
MatchState | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*name=None*, *bits=None*)

**Parameters**

- **name** (*str | None*)
- **bits** (*int | None*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.**PReinterpret**

Bases: PatternExpr

Matches a Reinterpret explicitly (never skipped): the bit pattern of a floating-point value read as an integer (from_type="F"), or an integer's bits viewed as a floating-point value (from_type="I").

**operand:** *PatternExpr*

**from_type:** str | None = None

**name:** str | None = None

**match**(*expr*, *state*, *ctx*)

**Return type**
MatchState | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*operand*, *from_type=None*, *name=None*)

**Parameters**

- **operand** (PatternExpr)
- **from_type** (*str | None*)
- **name** (*str | None*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.**PReturn**

Bases: *PatternStmt*

Matches a Return. `values` constrains the returned expressions, one pattern each; None matches a return of any arity.

**values:** tuple[*PatternExpr*, ...] | None = None

**optional:** bool = False

**weight:** float = 1.0

**match**(*stmt*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **stmt** (Statement)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*values=None*, *, *optional=False*, *weight=1.0*)

**Parameters**

- **values** (*tuple[PatternExpr, ...] | None*)
- **optional** (*bool*)
- **weight** (*float*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.**PStackField**

Bases: *PatternExpr*

A field of a container that lives on the stack.

A stack object never reaches the matcher as an object at all: variable recovery has already split it into one virtual variable per slot, so `std::string s;` is a handful of independent `vvar{s-112}`, `vvar{s-96}` and there is no `Load(s)` to match and no `s + 16` to compare against. Measured over the benchmark corpus (*kp-eval/stack_share.py*), stack objects are 40-54% of the DWARF sites for `std::string::length` and 15-35% for `std::vector<T>::size`.

This node matches the slot of the field at `offset` and binds `base` to the object's own stack offset, so two fields of one object unify on it exactly as `PField`'s two displacements do. `as_address` matches the address form (`&slot`, which lifts to `UnaryOp("Reference", vvar)`) rather than the value form; `std::string::capacity` needs both, since it compares the data pointer against the address of the local buffer.

The binding is a `StackBaseOffset`, the object's own address. That is both the thing two fields must agree on and, directly, the argument the synthesized call takes, so nothing has to be materialized for it.

Matching is only half the problem, and the other half is why a pattern using this node is never outlined: the region for a stack container reads N independent slots, so its live-ins are N values rather than one pointer and there is nothing for a synthesized callee to take. Such a match is instead rewritten in place: the matched expression, or the whole region, is replaced by `call(&s)`, whose argument the binding already is. See `KnownPatternFinder._rewrite_in_place` and `_rewrite_graph_in_place`.

**base:** str

**offset:** int

**as_address:** bool = False

**size:** int | None = None

**name:** str | None = None

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*base*, *offset*, *as_address=False*, *size=None*, *name=None*)

**Parameters**

- **base** (*str*)
- **offset** (*int*)
- **as_address** (*bool*)
- **size** (*int | None*)
- **name** (*str | None*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.**PStmtSeq**

Bases: *PatternStmt*

Matches a group of statements within one block. When `ordered` (the default), the statement patterns must match in order; with `allow_gaps`, unrelated statements may sit between the matched ones. When `ordered` is False, the statement patterns match statements of the block in any order (each pattern to a distinct statement), which suits idioms whose statement order the compiler chooses freely (e.g. list-link stores).

**stmts:** tuple[*PatternStmt*, ...]

**allow_gaps:** bool = True

**ordered:** bool = True

**max_gap:** int = 8

How many unmatched statements may sit between two matched ones. Without a bound the scan runs to the end of the block from every statement it could start at, quadratic per block per template, and finds nothing: an idiom's statements are adjacent apart from what the scheduler interleaved, which is a handful of instructions rather than a basic block.

**__init__**(*stmts*, *allow_gaps=True*, *ordered=True*, *max_gap=8*)

**Parameters**

- **stmts** (*tuple[PatternStmt, ...]*)
- **allow_gaps** (*bool*)
- **ordered** (*bool*)
- **max_gap** (*int*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.**PStore**

Bases: *PatternStmt*

Matches a Store statement. `size` is in bytes.

**addr:** *PatternExpr*

**value:** *PatternExpr*

**size:** `int | None = None`

**optional:** `bool = False`

the statement may be absent from an occurrence

**Type**
fuzzy matching only

**weight:** `float = 1.0`

relative contribution to an occurrence's score

**Type**
fuzzy matching only

**match**(*stmt*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **stmt** (Statement)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*addr*, *value*, *size=None*, ***, *optional=False*, *weight=1.0*)

**Parameters**

- **addr** (PatternExpr)
- **value** (PatternExpr)
- **size** (*int | None*)
- **optional** (*bool*)
- **weight** (*float*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.**PUnaryOp**

Bases: *PatternExpr*

Matches a UnaryOp.

**op:** str | frozenset[str]

**operand:** *PatternExpr*

**name:** str | None = None

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*op*, *operand*, *name=None*)

**Parameters**

- **op** (*str | frozenset[str]*)
- **operand** (PatternExpr)
- **name** (*str | None*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.**PVVar**

Bases: *PatternExpr*

Matches a VirtualVariable.

**name:** str | None = None

**bits:** int | None = None

**categories:** frozenset[VirtualVariableCategory] | None = None

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*name=None*, *bits=None*, *categories=None*)

**Parameters**

- **name** (*str | None*)
- **bits** (*int | None*)
- **categories** (*frozenset[VirtualVariableCategory] | None*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.**PatternContext**

Bases: object

Target facts used to instantiate pattern templates.

The last two fields are binary evidence: facts about what kind of program this is, used by *gating* to switch whole pattern families on for targets where the idioms are certain to appear and off everywhere else.

**arch_name:** str

**bits:** int

**ptr_size:** int

**platform:** str | None

**cxx_runtime:** str | None

**is_cpp:** bool

**is_linux_kernel_object:** bool = False

**is_windows_kernel_driver:** bool = False

**classmethod from_project**(*project*)

**Return type**
*PatternContext*

**Parameters**
**project** (Project)

**word**(*n*)

Byte offset of the n-th pointer-word field.

**Return type**
int

**Parameters**
**n** (*int*)

**property word_size:** int

Load size (bytes) of a pointer / size_t field.

**property language:** str

__init__(*arch_name*, *bits*, *ptr_size*, *platform*, *cxx_runtime*, *is_cpp*, *is_linux_kernel_object=False*, *is_windows_kernel_driver=False*)

**Parameters**

- **arch_name** (*str*)
- **bits** (*int*)
- **ptr_size** (*int*)
- **platform** (*str | None*)
- **cxx_runtime** (*str | None*)
- **is_cpp** (*bool*)
- **is_linux_kernel_object** (*bool*)
- **is_windows_kernel_driver** (*bool*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.**PatternGate**

Bases: object

Base class for template gates. Instances are callables so that a gate can be used anywhere a `Callable[[GateContext], bool]` is expected.

**opens**(*gctx*)

**Return type**
bool

**Parameters**
**gctx** (GateContext)

**property requires_evidence: bool**

Whether this gate can only be decided once the function's matches are known. Such gates are evaluated a second time by the finder.

**property label: str**

**__init__**()

**Return type**
None

exception angr.analyses.decompiler.known_patterns.**PatternGenerationError**

Bases: Exception

Raised when a selection cannot be turned into a KnownPattern (ambiguous, unsupported, or inconsistent with the given arguments).

class angr.analyses.decompiler.known_patterns.**PatternGenerator**

Bases: object

Generate a KnownPattern from a text selection in `codegen.text`.

**Parameters**

- **codegen** – the `Decompiler.codegen` (a `CStructuredCodeGenerator`).

- **ail_graph** (DiGraph | None) – the graph the generated pattern will be matched against (`Decompiler.ail_graph`). Required for multi-block (control-flow-spanning) selections; optional otherwise.

**__init__**(*codegen*, *ail_graph=None*)

**Parameters**
**ail_graph** (*networkx.DiGraph | None*)

**vvar_id_at**(*offset*)

The AIL vvar id of the variable rendered at `offset`, or None.

**Return type**
int | None

**Parameters**
**offset** (*int*)

**offset_of**(*needle*, *start=0*)

Convenience: the offset of `needle` in the rendered text.

**Return type**
int

**Parameters**

- **needle** (*str*)
- **start** (*int*)

**generate**(*start_offset*, *end_offset*, *call_name*, *arg_offsets*, ***, *name=None*, *display_name=None*, *returnty=None*, *param_types=None*, *const_arg_offsets=()*, *arches=None*, *platforms=None*, *binary_guard=None*, *default_enabled=False*)

**Return type**
*KnownPattern*

**Parameters**

- **start_offset** (*int*)
- **end_offset** (*int*)
- **call_name** (*str*)
- **arg_offsets** (*Sequence[int]*)
- **name** (*str | None*)
- **display_name** (*str | None*)
- **returnty** (TypeRef | *None*)
- **param_types** (*Sequence[TypeRef | None] | None*)
- **const_arg_offsets** (*Sequence[int]*)
- **arches** (*tuple[str, ...] | None*)
- **platforms** (*tuple[str, ...] | None*)
- **default_enabled** (*bool*)

**generate_pattern**(*start_offset*, *end_offset*, *call_name*, *, *name=None*, *display_name=None*, *returnty=None*, *param_types=None*)

A pattern for the fuzzy matcher from the statements the selection covers.

Unlike `generate()`, this asks nothing of the user beyond the span: every whole statement inside it becomes a leaf, a statement the DSL cannot express becomes a `PAnyStmt` rather than an error, and the call's parameters are the variables the statements read without defining, in the order they are first read. Constants stay exact; the editor is where they are loosened.

**Return type**
*KnownPattern*

**Parameters**

- **start_offset** (*int*)
- **end_offset** (*int*)
- **call_name** (*str*)
- **name** (*str | None*)
- **display_name** (*str | None*)
- **returnty** (TypeRef | *None*)
- **param_types** (*Sequence[TypeRef | None] | None*)

**generate_pattern_from_statements**(*stmts*, *call_name*, *, *name=None*, *display_name=None*, *returnty=None*, *param_types=None*)

`generate_pattern()` for a caller that already holds the statements, in order.

**Return type**
*KnownPattern*

**Parameters**

- **stmts** (*Sequence[Statement]*)
- **call_name** (*str*)
- **name** (*str | None*)
- **display_name** (*str | None*)
- **returnty** (TypeRef | *None*)
- **param_types** (*Sequence[TypeRef | None] | None*)

**class** angr.analyses.decompiler.known_patterns.**PatternParam**

Bases: object

One parameter of the synthesized call.

**Variables**

- **capture** (str) – Name of the pattern capture bound to this parameter.
- **type** (str | *CppRef* | None) – Argument type for the synthesized call's prototype; flows into Typehoon as a per-argument subtype constraint.
- **type_hint** – Optional cpp::std unique name emitted as a direct vvar type hint (for by-value captures where the vvar *is* the object rather than a pointer to it).

**capture:** str

**type:** str | *CppRef* | None = None

**type_hint:** str | None = None

**__init__**(*capture*, *type=None*, *type_hint=None*)

**Parameters**

- **capture** (*str*)
- **type** (*str | CppRef | None*)
- **type_hint** (*str | None*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.**TargetGate**

Bases: *PatternGate*

Opens when a predicate over the target's PatternContext holds.

The predicate reads facts that were derived once from the loaded binary, so evaluating it is free and its result is the same for every function.

**name:** str

**predicate:** Callable[[*PatternContext*], bool]

**opens**(*gctx*)

**Return type**
bool

**Parameters**
**gctx** (GateContext)

**property label:** str

**__init__**(*name*, *predicate*)

**Parameters**

- **name** (*str*)
- **predicate** (*Callable[[PatternContext], bool]*)

**Return type**
None

**exception** angr.analyses.decompiler.known_patterns.**UnknownPatternError**

Bases: ValueError

Raised when a pattern selection names a template that is not registered.

**exception** angr.analyses.decompiler.known_patterns.**UnsupportedOutlineError**

Bases: Exception

Raised when a match cannot be safely outlined (e.g. side-effecting statements interleave with the matched span, or the recovered callee interface does not agree with the pattern's declared parameters).

angr.analyses.decompiler.known_patterns.**all_of**(**gates*)

**Return type**
*AllOf*

**Parameters**
**gates** (PatternGate)

angr.analyses.decompiler.known_patterns.**any_of**(**gates*)

**Return type**
*AnyOf*

**Parameters**
**gates** (PatternGate)

angr.analyses.decompiler.known_patterns.**corroborated_by**(**witnesses*)

A gate that opens in a function where one of `witnesses` matched.

**Return type**
*CorroboratedBy*

**Parameters**
**witnesses** (*str*)

angr.analyses.decompiler.known_patterns.**exact_div_magic**(*elt_size*, *bits*)

`(shift, magic)` of the exact-division-by-`elt_size` idiom.

**Return type**
tuple[int, int]

**Parameters**

- **elt_size** (*int*)
- **bits** (*int*)

angr.analyses.decompiler.known_patterns.**has_fuzzy_nodes**(*node*)

Whether node can only be matched by the fuzzy matcher.

An optional statement has no meaning to the exact matcher, which either finds every statement pattern or fails; a pattern carrying one has to be kept away from it rather than silently matched as if the statement were required.

**Return type**
bool

**Parameters**
**node** (PatternNode)

angr.analyses.decompiler.known_patterns.**iter_stmt_patterns**(*node*)

Every leaf statement pattern under node, in pattern order.

**Return type**
Iterator[*PAssign* | *PStore* | *PCallStmt* | *PCondJump* | *PReturn* | *PAnyStmt*]

**Parameters**
**node** (PatternNode)

angr.analyses.decompiler.known_patterns.**make_std_vector_size_exactdiv_template**(*elt_name*, *elt_size*)

A non-power-of-two `std::vector<elt_name>::size` template.

**Parameters**

- **elt_name** (*str*)
- **elt_size** (*int*)

angr.analyses.decompiler.known_patterns.**make_std_vector_size_template**(*elt_name*, *log2_elt_size*)

A power-of-two `std::vector<elt_name>::size` template.

**Parameters**

- **elt_name** (*str*)
- **log2_elt_size** (*int*)

angr.analyses.decompiler.known_patterns.**make_template**(*call_name*, *build*, ***, *arches=None*, *languages=None*, *runtimes=None*, *platforms=None*, *default_enabled=False*, *name=''*, *gate=None*)

**Return type**
*KnownPatternTemplate*

**Parameters**

- **call_name** (*str*)
- **build** (*Callable[[PatternContext], KnownPattern | None]*)
- **arches** (*frozenset[str] | tuple[str, ...] | None*)
- **languages** (*frozenset[str] | tuple[str, ...] | None*)
- **runtimes** (*frozenset[str] | tuple[str, ...] | None*)
- **platforms** (*frozenset[str] | tuple[str, ...] | None*)
- **default_enabled** (*bool*)
- **name** (*str*)
- **gate** (*PatternGate | None*)

angr.analyses.decompiler.known_patterns.**partition_templates**(*gate_ctx*, *forced=()*, *templates=None*)

Split templates into `(enabled, deferred)` for one target.

`enabled` are the templates to match with right away: default-on ones, ones the caller force-enabled, and ones whose gate already opens on target evidence alone. `deferred` are the ones whose gate needs per-function evidence (see *CorroboratedBy*) and must be re-evaluated by the finder once the first matching stage has run.

**Return type**
tuple[list[*KnownPatternTemplate*], list[*KnownPatternTemplate*]]

**Parameters**

- **gate_ctx** (GateContext)
- **forced** (*Iterable[KnownPatternTemplate]*)
- **templates** (*Iterable[KnownPatternTemplate] | None*)

angr.analyses.decompiler.known_patterns.**patterns_for**(*ctx*, *templates=None*, ***, *enabled_only=False*)

Instantiate the applicable templates for `ctx` into concrete KnownPatterns. `templates` defaults to the whole registry; with `enabled_only` only default-enabled templates are used.

**Return type**
list[*KnownPattern*]

**Parameters**

- **ctx** (PatternContext)
- **templates** (*Iterable[KnownPatternTemplate] | None*)
- **enabled_only** (*bool*)

angr.analyses.decompiler.known_patterns.**register_pattern_template**(*template*)

Register a KnownPatternTemplate. Call names are unique across templates (the architecture / runtime conditionals live inside each template's `build`).

**Return type**
None

**Parameters**
**template** (KnownPatternTemplate)

angr.analyses.decompiler.known_patterns.**resolve_pattern_selection**(*selection*)

Resolve a user's force-enable selection into templates.

`selection` is one of:

- `None` / empty: nothing is force-enabled (returns an empty list);
- `"all"`: every registered template, opt-in ones included;
- an iterable of template `name` and/or `call_name` values (a comma-separated string is accepted too, for the string-valued decompilation option).

An unrecognized name raises `UnknownPatternError` rather than silently selecting nothing.

**Return type**
list[*KnownPatternTemplate*]

**Parameters**
**selection** (*str | Iterable[str] | None*)

### Submodules

| | |
|---|---|
| *apply* | Apply call-site information (prototypes) for known-pattern calls. |
| *block_split* | Utilities for splitting an AIL block into consecutive blocks within a graph. |
| *containing_record* | The CONTAINING_RECORD macro (Windows drivers) / container_of (Linux kernel). |
| *context* | PatternContext: the architecture / platform / language facts a KnownPattern template needs to instantiate itself for a given binary. |
| *ctype_tables* | The glibc ctype macros: isspace, isdigit, . |
| *dsl* | Declarative pattern-AST for describing known AIL code idioms (KnownPatterns). |
| *edit* | Edit a pattern the way a visual editor does: by node, with undo. |
| *finder* | KnownPatternFinder: find occurrences of KnownPatterns in a Clinic AIL graph and outline them into calls via the Outliner analysis. |
| *gating* | Criteria gates: per-target (and per-function) enablement for pattern templates. |

continues on next page

Table 15 – continued from previous page

| | |
|---|---|
| *generator* | PatternGenerator: build a KnownPattern from a decompilation text selection. |
| *kernel_err* | Linux kernel <linux/err.h> error-pointer idioms. |
| *layouts* | Runtime-specific struct layout offsets for the STL container patterns. |
| *libm_bits* | libm floating-point bit-twiddling idioms (fabs / -x / copysign / isnan / isinf). |
| *linked_list* | Doubly-linked-list idioms shared by Windows LIST_ENTRY (Flink/Blink) and Linux kernel list_head (next/prev): the same two-pointer layout, so one set of templates matches both WDK drivers and kernel/Boost-intrusive code. |
| *pattern* | KnownPattern: declarative metadata around a pattern-AST. |
| *posix_macros* | Single-expression glibc/POSIX macros that the preprocessor inlines into every caller, so they survive into decompiled output as bare bit arithmetic. |
| *protobuf_hasbits* | protobuf has-bits accessors (protoc output for optional fields). |
| *registry* | The template registry: every KnownPatternTemplate the package defines, keyed by call name and by human name, plus the helpers that turn a user's selection or a target's gates into the list of templates to match with. |
| *serialize* | JSON round-trip for the plain-data subset of the pattern DSL. |
| *std_string_cstr* | Inlined MSVC std::string::c_str() / data(): the small-string optimization (SSO) select. |
| *std_string_dtor* | The inlined std::string destructor. |
| *std_string_internals* | libstdc++ std::string internals that are not accessors: the SSO test and the two length-setting idioms. |
| *std_string_length* | Inlined std::string::length() / size() and empty(). |
| *std_swap* | Inlined std::swap, the three-move exchange of two memory locations. |
| *std_vector_size* | Inlined std::vector<T>::size() and capacity(). |
| *stl_accessors2* | C++ STL accessors, round two: std::string capacity/back/front and std::vector<T>::back(). |
| *stl_containers* | C++ STL std::vector accessors beyond size()/capacity(): empty / operator[]. |
| *symbols* | Symbol names as the portable spelling of an address. |
| *templates* | KnownPatternTemplate: a single, context-parameterized definition of an idiom that instantiates itself into a concrete KnownPattern for a target's PatternContext. |
| *vector_claims* | Claims-only std::vector fingerprints: shapes that identify a vector beyond doubt but are not worth a call of their own. |
| *vector_math* | 3-component float vector math (glm / DirectXMath / game-graphics code). |

| | |
|---|---|
| *wdk_shared_data* | Reads of KUSER_SHARED_DATA, the page Windows maps read-only at the fixed virtual address 0x7FFE0000 in every user-mode process (x86, x64 and ARM64 alike). ntdll, kernel32 and countless drivers read its fields through the SharedUserData macro of nt-ddk.h/wdm.h, which compiles to a bare load from an absolute constant address::. |

### angr.analyses.decompiler.known_patterns.apply

Apply call-site information (prototypes) for known-pattern calls.

Known-pattern calls are identified by their string target, which is stable across Clinic runs; the VariableMap holding prototypes is scoped to a single Clinic run. This helper (re)applies the prototypes onto a graph's calls so that variable recovery emits per-argument type constraints for Typehoon. It is used by the KnownPatternOutliner optimization pass (which runs after the peephole stages) and mirrors what the KnownPatternCallInfo peephole does for graphs that already contain known-pattern calls at the start of a run.

angr.analyses.decompiler.known_patterns.apply.**prototype_for_call**(*project*, *call*)

The ctx-instantiated prototype for a known-pattern call, or None. The return-type width and argument pointer sizes follow the target's PatternContext.

**Parameters**

- **project** (Project)
- **call** (Call)

angr.analyses.decompiler.known_patterns.apply.**apply_call_info_to_graph**(*graph*, *manager*, *project*)

Set the call-site prototype of every known-pattern call in graph in the VariableMap attached to manager. Returns the number of calls that received a prototype.

**Return type**
int

**Parameters**

- **graph** (*networkx.DiGraph*)
- **manager** (*Manager*)
- **project** (Project)

### angr.analyses.decompiler.known_patterns.block_split

Utilities for splitting an AIL block into consecutive blocks within a graph.

The Outliner analysis operates at whole-block granularity, while KnownPattern matches are usually (sub-)statement-level; splitting the anchor block so the matched span becomes its own block bridges the two.

angr.analyses.decompiler.known_patterns.block_split.**rewrite_phi_sources**(*block*, *old_src*, *new_src*, *idx_alloc*)

Rewrite phi statements at the top of block so that entries sourced from old_src are sourced from new_src instead. Mutates the block's statement list in place.

idx_alloc supplies AIL indices for the rebuilt statements: an object built with idx=None lands at index 0, and the decompiler's VariableMap is keyed by index, so all of them would share one entry.

**Return type**
None

**Parameters**

- **block** (Block)
- **old_src** (*tuple[int, int]*)
- **new_src** (*tuple[int, int]*)
- **idx_alloc** (*Callable[[], int]*)

angr.analyses.decompiler.known_patterns.block_split.**split_ail_block**(*graph*, *block*, *pre_stmts*, *mid_stmts*, *post_stmts*, *block_addr_alloc*, *idx_alloc*)

Replace `block` in `graph` with up to three consecutive blocks holding `pre_stmts`, `mid_stmts`, and `post_stmts`.

The first non-empty part keeps the original block identity `(addr, idx)` so that predecessor jump targets (and the at-most-one-block-per-address assumption at the function entry) remain valid; each following part is placed at a fresh synthetic address obtained from `block_addr_alloc`. When the last part's identity differs from the original, phi statements in the successors are rewritten to source from the new last block. Edge data is preserved.

Returns `(b_pre, b_mid, b_post)` where `b_pre`/`b_post` are None when their statement list is empty. `mid_stmts` must be non-empty.

**Return type**
tuple[Block | None, Block, Block | None]

**Parameters**

- **graph** (*networkx.DiGraph*)
- **block** (Block)
- **pre_stmts** (*Sequence[Statement]*)
- **mid_stmts** (*Sequence[Statement]*)
- **post_stmts** (*Sequence[Statement]*)
- **block_addr_alloc** (*Callable[[], int]*)
- **idx_alloc** (*Callable[[], int]*)

### angr.analyses.decompiler.known_patterns.containing_record

The CONTAINING_RECORD macro (Windows drivers) / container_of (Linux kernel):

```
CONTAINING_RECORD(addr, type, field) == (type *)((char *)addr - offsetof(...))
```

which compiles to a bare pointer-minus-small-constant, `(p Sub off)`. Too generic to run unsolicited (any pointer arithmetic matches), so opt-in. The matched offset is captured as an extra call argument, and the return type is a pointer to a record struct reserving the leading `off` bytes (so Typehoon can grow it from the record's field accesses).

Arch-independent shape (the offset is a captured constant, not word-scaled).

Three qualifications keep the presentation honest, all measured against putty (user-space C, 139 real uses, DWARF `offsetof` as the oracle):

- One call per idiom. No compiler keeps the adjusted pointer around: it folds the subtraction into every field displacement that reads through it, so one source `container_of` reached the matcher as 3.4 separate matches on the same base, each naming a record base wrong by that field's offset (83.5% of the non-genuine matches were

explained this way, against 13.0% for random offsets). `collapse_capture` keeps one match per base pointer; the largest offset is the right one to keep, since a field at member offset `m` of the record appears as `p - (off - m)` and so can only shrink the constant. Measured: this reports the true `container_of` offset for 80.1% (gcc) / 86.7% (clang) of base pointers, against 29% for the per-field matches.

- An offset floor. `p - 1` is a decrement, not a record base; offsets below one machine word carry no record. 29 of the 85 distinct offsets emitted in container_of-free code were exactly 1.

Rejected: requiring the result to be dereferenced. The captured base is a bare virtual variable of unknown type, so a decrement matches as happily as a record base, and demanding that the adjusted pointer sit inside a memory address looks like the way to tell them apart. It selects the wrong cases. The folded form is a field load and passes; the unfolded form, the one that survives because the code does something with the record other than read one field of it, which is the case the pattern gets right, does not, since the pointer is handed to a callee or stored. Measured on putty/gcc it dropped function-level recall from 90.7% to 65.0% and site-level recall from 42.7% to 2.1%, and it also rejects the `sum_list` fixture below. The offset floor already removes the decrements it was aimed at.

### angr.analyses.decompiler.known_patterns.context

PatternContext: the architecture / platform / language facts a KnownPattern template needs to instantiate itself for a given binary.

A pattern is defined once as a `KnownPatternTemplate` whose `build(ctx)` computes concrete field offsets, load sizes, and return types from a `PatternContext`, so a single definition covers 32- and 64-bit, libstdc++ and MSVC, etc.

angr.analyses.decompiler.known_patterns.context.**size_t_typename**(*bits*)

The C spelling of size_t for a given word width.

**Return type**
str

**Parameters**
**bits** (*int*)

angr.analyses.decompiler.known_patterns.context.**detect_linux_kernel_object**(*project*)

Whether the main object is a Linux kernel module or the kernel image.

Sections are checked first because they are the cheap and decisive signal: modpost emits `.modinfo` and `.gnu.linkonce.this_module` into every `.ko`, and they survive stripping. The `__ksymtab`/`__kcrctab` symbol scan additionally catches a vmlinux and modules whose section names were renamed.

**Return type**
bool

**Parameters**
**project** (Project)

angr.analyses.decompiler.known_patterns.context.**detect_windows_kernel_driver**(*project*)

Whether the main object is a Windows kernel-mode driver, i.e. imports the kernel executive / HAL / a kernel-mode port or class library instead of the user-mode Win32 DLLs.

**Return type**
bool

**Parameters**
**project** (Project)

angr.analyses.decompiler.known_patterns.context.**detect_cxx_runtime**(*project*)

Identify the C++ standard-library runtime: `"msvc"`, `"libstdcxx"`, or None. Mirrors the old is_cpp_binary /

is_msvc_cpp_binary heuristics: dependency names first, then mangled-symbol evidence (mingw PEs link libstdc++ and use its layouts even though they are PEs), then, for statically linked, stripped binaries that carry neither, RTTI type descriptors embedded in data sections.

**Return type**
str | None

**Parameters**
**project** (Project)

**class** angr.analyses.decompiler.known_patterns.context.**PatternContext**

Bases: object

Target facts used to instantiate pattern templates.

The last two fields are binary evidence: facts about what kind of program this is, used by *gating* to switch whole pattern families on for targets where the idioms are certain to appear and off everywhere else.

**arch_name:** str

**bits:** int

**ptr_size:** int

**platform:** str | None

**cxx_runtime:** str | None

**is_cpp:** bool

**is_linux_kernel_object:** bool = False

**is_windows_kernel_driver:** bool = False

**classmethod from_project**(*project*)

**Return type**
*PatternContext*

**Parameters**
**project** (Project)

**word**(*n*)

Byte offset of the n-th pointer-word field.

**Return type**
int

**Parameters**
**n** (*int*)

**property word_size:** int

Load size (bytes) of a pointer / size_t field.

**property language:** str

**__init__**(*arch_name*, *bits*, *ptr_size*, *platform*, *cxx_runtime*, *is_cpp*, *is_linux_kernel_object=False*, *is_windows_kernel_driver=False*)

**Parameters**

- **arch_name** (*str*)

- **bits** (*int*)
- **ptr_size** (*int*)
- **platform** (*str | None*)
- **cxx_runtime** (*str | None*)
- **is_cpp** (*bool*)
- **is_linux_kernel_object** (*bool*)
- **is_windows_kernel_driver** (*bool*)

**Return type**
None

### angr.analyses.decompiler.known_patterns.ctype_tables

The glibc ctype macros: isspace, isdigit, … and tolower/toupper.

<ctype.h> classifies a character by indexing a locale table rather than by comparing ranges:

```
#define __isctype(c, type)  ((*__ctype_b_loc ())[(int) (c)] & (unsigned short int) type)
```

so `isspace(c)` compiles to a call to `__ctype_b_loc`, a load of the table pointer it returns, a 16-bit indexed load, and a mask. Every predicate is that one shape with a different constant, which is why they are generated here rather than written out.

Measured over the -O2 benchmark corpus, the eleven predicates account for 7,894 macro-oracle sites across 24 projects, wider project coverage than any family KnownPatterns covers today, with `tolower` and `toupper` adding 1,588 more.

The callee is what makes the whole family self-guarding: nothing else calls `__ctype_b_loc`. *PCallResult* binds the table to that call without consuming it, which matters because the compiler hoists the call out of loops and indexes the table from every predicate in the function.

Two byte lanes. glibc's `_ISbit(n)` is `n < 8 ? (1 << n) << 8 : (1 << n) >> 8`, so eight of the twelve masks live in the high byte of the table entry and four in the low byte, and gcc tests a byte rather than the 16-bit word. Hence three spellings per predicate rather than one: the mask as written against the whole entry, and, for a high mask, an 8-bit slice at byte 1 against the mask's high byte (`test $0x20,%ah`) or that byte loaded on its own (`testb $0x20, 1(%rax,%rdx,2)`); for a low mask, an 8-bit slice at byte 0. The slice spellings are not interchangeable with the first: structural matching skips a Convert and does not skip an Extract.

Calibrated against tests/x86_64/decompiler/known_patterns_ctype (gcc 12.2.0 -O2).

angr.analyses.decompiler.known_patterns.ctype_tables.**CTYPE_B_LOC = frozenset({'___ctype_b_loc', '__ctype_b_loc'})**

glibc's `__ctype_b_loc` under every spelling a binary may know it by.

angr.analyses.decompiler.known_patterns.ctype_tables.**CTYPE_PREDICATES: tuple[tuple[str, int], ...] = (('isupper', 256), ('islower', 512), ('isalpha', 1024), ('isdigit', 2048), ('isxdigit', 4096), ('isspace', 8192), ('isprint', 16384), ('isgraph', 32768), ('isblank', 1), ('iscntrl', 2), ('ispunct', 4), ('isalnum', 8))**

`(macro name, mask)`. The values are glibc's `enum` from <ctype.h>, computed by `_ISbit(n) = n < 8 ? (1 << n) << 8 : (1 << n) >> 8`.

### angr.analyses.decompiler.known_patterns.dsl

Declarative pattern-AST for describing known AIL code idioms (KnownPatterns).

Pattern nodes are frozen dataclasses that structurally match AIL expressions and statements. Every node accepts an optional `name`: a named *capture*. When the same capture name occurs more than once in a pattern, all occurrences must bind `.likes()`-equal expressions (unification).

Matching is performed by calling `PatternNode.match()` with a *MatchState* (the bindings environment) and a *MatchCtx* (matcher-wide flags and callbacks). Match methods are functional: they return a new `MatchState` on success and `None` on failure, so alternatives (commutative operand orders, *PChoice*) can backtrack by reusing the pre-branch state.

**class** angr.analyses.decompiler.known_patterns.dsl.**MatchState**

Bases: object

The bindings environment threaded through a match attempt.

**bindings:** dict[str, *Expression*]

**consumed_stmt_idxs:** frozenset[int] = frozenset({})

**chased_defs:** tuple[tuple[int, int], ...] = ()

**remote_defs:** tuple[tuple[int, *Expression*], ...] = ()

**skipped_converts:** tuple[*Convert* | *Reinterpret*, ...] = ()

**base_aliases:** tuple[tuple[int, int, int], ...] = ()

**bind**(*name*, *expr*)

Bind `name` to `expr`; on rebind, require `.likes()` equality.

**Return type**
*MatchState* | None

**Parameters**

- **name** (*str*)
- **expr** (Expression)

**__init__**(*bindings=<factory>*, *consumed_stmt_idxs=frozenset({})*, *chased_defs=()*, *remote_defs=()*, *skipped_converts=()*, *base_aliases=()*)

**Parameters**

- **bindings** (*dict[str, Expression]*)
- **consumed_stmt_idxs** (*frozenset[int]*)
- **chased_defs** (*tuple[tuple[int, int], ...]*)
- **remote_defs** (*tuple[tuple[int, Expression], ...]*)
- **skipped_converts** (*tuple[Convert | Reinterpret, ...]*)
- **base_aliases** (*tuple[tuple[int, int, int], ...]*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.dsl.**MatchCtx**

Bases: object

Matcher-wide flags and callbacks.

**ptr_bits**: int | None = None

**skip_conversions**: bool = True

**skip_conversions_at_leaves**: bool = False

also step over Convert wrappers right above a variable or constant leaf. The exact library keeps this off: its patterns spell out the conversions they expect. A pattern lifted from a selection has had them dropped, since the generator mirrors the structural nodes' skipping, so it needs the leaves to skip as well or it cannot match the statements it came from.

**chase_fn**: Callable[[int], tuple[int, *Expression*] | None] | None = None

**peek_fn**: Callable[[int], *Expression* | None] | None = None

**remote_chase_fn**: Callable[[int], *Expression* | None] | None = None

**stack_slot_fn**: Callable[[int], *VirtualVariable* | None] | None = None

**call_target_fn**: Callable[[*Call*], frozenset[str]] | None = None

**next_idx**()

**Return type**
int

**def_fn**: Callable[[int], *Expression* | None] | None = None

**symbol_addr_fn**: Callable[[str], int | None] | None = None

**__init__**(*ptr_bits=None*, *skip_conversions=True*, *skip_conversions_at_leaves=False*, *chase_fn=None*, *peek_fn=None*, *remote_chase_fn=None*, *stack_slot_fn=None*, *call_target_fn=None*, *next_idx=<function _standalone_idx>*, *def_fn=None*, *symbol_addr_fn=None*)

**Parameters**

- **ptr_bits** (*int | None*)
- **skip_conversions** (*bool*)
- **skip_conversions_at_leaves** (*bool*)
- **chase_fn** (*Callable[[int], tuple[int, Expression] | None] | None*)
- **peek_fn** (*Callable[[int], Expression | None] | None*)
- **remote_chase_fn** (*Callable[[int], Expression | None] | None*)
- **stack_slot_fn** (*Callable[[int], VirtualVariable | None] | None*)
- **call_target_fn** (*Callable[[Call], frozenset[str]] | None*)
- **next_idx** (*Callable[[], int]*)
- **def_fn** (*Callable[[int], Expression | None] | None*)
- **symbol_addr_fn** (*Callable[[str], int | None] | None*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.dsl.**PatternNode**

Bases: object

Base class of all pattern nodes.

class angr.analyses.decompiler.known_patterns.dsl.**PatternExpr**

Bases: *PatternNode*

Base class of expression patterns.

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

class angr.analyses.decompiler.known_patterns.dsl.**PAny**

Bases: *PatternExpr*

Matches any expression.

**name:** str | None = None

**bits:** int | None = None

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*name=None*, *bits=None*)

**Parameters**

- **name** (*str | None*)
- **bits** (*int | None*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.dsl.**PVVar**

Bases: *PatternExpr*

Matches a VirtualVariable.

**name:** str | None = None

**bits:** int | None = None

**categories:** frozenset[VirtualVariableCategory] | None = None

**match**(*expr*, *state*, *ctx*)

**Return type**
MatchState | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*name=None*, *bits=None*, *categories=None*)

**Parameters**

- **name** (*str | None*)
- **bits** (*int | None*)
- **categories** (*frozenset[VirtualVariableCategory] | None*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.dsl.**PConst**

Bases: PatternExpr

Matches a Const, by exact value or by predicate. Width is ignored unless `bits` is given (e.g. shift amounts are often 8-bit).

**value:** int | None = None

**pred:** Callable[[int], bool] | None = None

**bits:** int | None = None

**name:** str | None = None

**values:** frozenset[int] | None = None

an enumerable set of acceptable values. Prefer this over `pred` when the set is known: the finder indexes patterns by the constants they accept, so a pattern is only tried where one of its constants occurs.

**symbol:** str | None = None

the address of this symbol in the binary being matched, resolved through `MatchCtx.symbol_addr_fn`; the portable spelling of a global's address

**match**(*expr*, *state*, *ctx*)

**Return type**
MatchState | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

__init__(*value=None*, *pred=None*, *bits=None*, *name=None*, *values=None*, *symbol=None*)

**Parameters**

- **value** (*int | None*)
- **pred** (*Callable[[int], bool] | None*)
- **bits** (*int | None*)
- **name** (*str | None*)
- **values** (*frozenset[int] | None*)
- **symbol** (*str | None*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.dsl.**PBinOp**

Bases: *PatternExpr*

Matches a BinaryOp. op may be a single op string or a set of acceptable ops. Commutative ops try both operand orders unless commutative is explicitly False.

**op:** `str | frozenset[str]`

**operands:** `tuple[PatternExpr, PatternExpr]`

**commutative:** `bool | None = None`

**name:** `str | None = None`

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

__init__(*op*, *operands*, *commutative=None*, *name=None*)

**Parameters**

- **op** (*str | frozenset[str]*)
- **operands** (*tuple[PatternExpr, PatternExpr]*)
- **commutative** (*bool | None*)
- **name** (*str | None*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.dsl.**PUnaryOp**

Bases: *PatternExpr*

Matches a UnaryOp.

**op:** str | frozenset[str]

**operand:** *PatternExpr*

**name:** str | None = None

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*op*, *operand*, *name=None*)

**Parameters**

- **op** (*str | frozenset[str]*)
- **operand** (PatternExpr)
- **name** (*str | None*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.dsl.**PConv**

Bases: *PatternExpr*

Matches a Convert explicitly (never skipped).

**operand:** *PatternExpr*

**from_bits:** int | None = None

**to_bits:** int | None = None

**name:** str | None = None

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*operand*, *from_bits=None*, *to_bits=None*, *name=None*)

**Parameters**

- **operand** (PatternExpr)
- **from_bits** (*int | None*)
- **to_bits** (*int | None*)

- **name** (*str | None*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.dsl.**PReinterpret**

Bases: *PatternExpr*

Matches a Reinterpret explicitly (never skipped): the bit pattern of a floating-point value read as an integer (`from_type="F"`), or an integer's bits viewed as a floating-point value (`from_type="I"`).

**operand:** *PatternExpr*

**from_type:** str | None = None

**name:** str | None = None

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*operand*, *from_type=None*, *name=None*)

**Parameters**

- **operand** (PatternExpr)
- **from_type** (*str | None*)
- **name** (*str | None*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.dsl.**PExtract**

Bases: *PatternExpr*

Matches an `Extract`, a bit-slice of a wider value.

This is how a scalar reaches integer code out of a vector register when the 128-bit op did not get narrowed away: `movq %xmm2,%rax` on a value that came from `maxsd`/`mulsd` lifts to `Extract(vvar_128, 64bits@0)` rather than to a Convert. Without a node for it, every libm bit-twiddle whose operand is a computed double rather than an incoming argument is unmatchable.

`bits`/`offset` default to unconstrained; `offset` is in bits.

**operand:** *PatternExpr*

**bits:** int | None = None

**offset:** int | None = None

**name:** str | None = None

match(*expr*, *state*, *ctx*)

**Return type**
MatchState | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

__init__(*operand*, *bits=None*, *offset=None*, *name=None*)

**Parameters**

- **operand** (PatternExpr)
- **bits** (*int | None*)
- **offset** (*int | None*)
- **name** (*str | None*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.dsl.PLoad

Bases: PatternExpr

Matches a memory Load. size is in bytes.

addr: *PatternExpr*

size: int | None = None

name: str | None = None

match(*expr*, *state*, *ctx*)

**Return type**
MatchState | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

__init__(*addr*, *size=None*, *name=None*)

**Parameters**

- **addr** (PatternExpr)
- **size** (*int | None*)
- **name** (*str | None*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.dsl.**PCall**

Bases: *PatternExpr*

Matches a `Call` whose callee is one of `names`.

The callee is what makes a pattern containing this node self-guarding: an idiom spelled around a named runtime function (`operator delete` in the std::string destructor, `__ctype_b_loc` in `isspace`) cannot be confused with arithmetic that happens to look alike, because no other code calls that function to do something else.

`names` is matched against every spelling the callee is known by (the raw symbol and its demangled form), so a pattern may name either. Prefer the mangled spelling: it is exact, while a demangled one carries the argument list and varies with the demangler.

`args=None` leaves the arguments unconstrained; a tuple constrains them positionally, with `None` in a slot meaning "any expression".

**names:** `frozenset[str]`

**args:** `tuple[PatternExpr | None, ...] | None = None`

**name:** `str | None = None`

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*names*, *args=None*, *name=None*)

**Parameters**

- **names** (*frozenset[str]*)
- **args** (*tuple[PatternExpr | None, ...] | None*)
- **name** (*str | None*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.dsl.**PCallResult**

Bases: *PatternExpr*

The value a call to one of `names` returned.

A call's result is rarely used where it is produced: the compiler assigns it to a register and reads that register, often in another block. `__ctype_b_loc()` is called once per function and its table indexed at every predicate. So this node matches the virtual variable and looks up its definition read-only. Nothing is consumed, moved or recomputed; the call stays where the compiler put it.

An inline `Call` expression is matched too, for the case where the value is used at its definition.

**names:** `frozenset[str]`

**name:** `str | None = None`

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*names*, *name=None*)

**Parameters**

- **names** (*frozenset[str]*)
- **name** (*str | None*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.dsl.**PDefOf**

Bases: *PatternExpr*

`inner`, or a virtual variable whose reaching definition is `inner`.

The compiler is free to compute a value once and use it twice, and it does so exactly where an idiom uses one value twice. `if (_M_p != &_M_local_buf) operator delete(_M_p, ...)` reads _M_p in the compare and in the call, so gcc loads it into a register and the pattern sees `Load(s)` in neither place; it sees the same virtual variable in both.

Reading that variable's definition is read-only. Nothing is consumed, moved or recomputed, and the identification stays accurate even if memory changes afterwards: the variable holds what the load produced at the definition, which is what the idiom meant. That is why this is not `peek_fn`, whose contract ("can be recomputed at the use") a load cannot satisfy.

The unconsumed definition is left where it was, so a region that matches through this node keeps it as residue. That is harmless, and dead-code elimination removes it once the idiom's other uses are gone.

**inner:** *PatternExpr*

**name:** str | None = None

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*inner*, *name=None*)

**Parameters**

- **inner** (PatternExpr)
- **name** (*str | None*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.dsl.**PField**

Bases: *PatternExpr*

The *address* of the field at `offset` inside the object bound to `base`.

Spelling a container's fields as `PLoad(PVVar("v"))` / `PLoad(PVVar("v") + 8)` requires the object to sit at the very address held in a virtual variable. That is the minority case: measured over the benchmark corpus, only 10-25% of the DWARF sites for a `std::vector` accessor read the container through a bare pointer; the rest reach it as a *field of something else* (`this->tokens.size()`), which lifts to `Load(this + 56)` / `Load(this + 64)` and cannot bind `v` at all.

`PField` matches such an address and binds `base` to the object's own address: `root` when the object is at offset 0, else `root + K`. Two fields of one object therefore unify on `K`, which is what keeps the node honest: it replaces the constraint "this displacement is exactly 8" with "these two displacements differ by exactly 8".

Only use it in patterns that reference at least two fields. With a single field there is no second displacement to constrain, so `PLoad(PField("s", 8))` degenerates into "any load through a pointer plus a non-negative constant" and matches essentially everything.

`root` must be a virtual variable: the outliner materializes `tmp = root + K` ahead of the region so the synthesized call still takes a variable.

**base:** *str*

**offset:** *int*

**name:** *str | None* = None

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*base*, *offset*, *name=None*)

**Parameters**

- **base** (*str*)
- **offset** (*int*)
- **name** (*str | None*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.dsl.**PStackField**

Bases: *PatternExpr*

A field of a container that lives on the stack.

A stack object never reaches the matcher as an object at all: variable recovery has already split it into one virtual variable per slot, so `std::string s;` is a handful of independent `vvar{s-112}`, `vvar{s-96}` and

there is no `Load(s)` to match and no `s + 16` to compare against. Measured over the benchmark corpus (*kp-eval/stack_share.py*), stack objects are 40-54% of the DWARF sites for `std::string::length` and 15-35% for `std::vector<T>::size`.

This node matches the slot of the field at `offset` and binds `base` to the object's own stack offset, so two fields of one object unify on it exactly as *PField*'s two displacements do. `as_address` matches the address form (`&slot`, which lifts to `UnaryOp("Reference", vvar)`) rather than the value form; `std::string::capacity` needs both, since it compares the data pointer against the address of the local buffer.

The binding is a `StackBaseOffset`, the object's own address. That is both the thing two fields must agree on and, directly, the argument the synthesized call takes, so nothing has to be materialized for it.

Matching is only half the problem, and the other half is why a pattern using this node is never outlined: the region for a stack container reads N independent slots, so its live-ins are N values rather than one pointer and there is nothing for a synthesized callee to take. Such a match is instead rewritten in place: the matched expression, or the whole region, is replaced by `call(&s)`, whose argument the binding already is. See `KnownPatternFinder._rewrite_in_place` and `_rewrite_graph_in_place`.

**base:** *str*

**offset:** *int*

**as_address:** *bool* = **False**

**size:** *int* | *None* = **None**

**name:** *str* | *None* = **None**

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*base*, *offset*, *as_address=False*, *size=None*, *name=None*)

**Parameters**

- **base** (*str*)
- **offset** (*int*)
- **as_address** (*bool*)
- **size** (*int | None*)
- **name** (*str | None*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.dsl.**PPhi**

Bases: *PatternExpr*

Matches a Phi expression, capturing it whole (its individual sources are not matched). Useful for loop-header blocks, whose statements are phi assignments.

**name:** *str | None = None*

**bits:** *int | None = None*

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*name=None*, *bits=None*)

**Parameters**

- **name** (*str | None*)
- **bits** (*int | None*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.dsl.**PITE**

Bases: *PatternExpr*

Matches an ITE (ternary) expression `cond ? iftrue : iffalse`.

Needed because ITERegionConverter (AFTER_GLOBAL_SIMPLIFICATION) collapses `if (c) x = a; else x = b;` diamonds into a single ITE assignment before the KnownPatternOutliner runs, so a two-armed value-select idiom reaches the outliner as an expression, not as a PGraphPat region. (A triangle, with one arm empty as in the MSVC std::string::c_str SSO select, is not converted, which is why that idiom is still a PGraphPat.)

**cond:** *PatternExpr*

**iftrue:** *PatternExpr*

**iffalse:** *PatternExpr*

**name:** *str | None = None*

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*cond*, *iftrue*, *iffalse*, *name=None*)

**Parameters**

- **cond** (PatternExpr)
- **iftrue** (PatternExpr)

- **iffalse** (PatternExpr)
- **name** (*str | None*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.dsl.**PChoice**

Bases: *PatternExpr*

Ordered alternation: matches the first alternative that succeeds.

**alternatives:** tuple[*PatternExpr*, ...]

**__init__**(**alternatives*)

**Parameters**
**alternatives** (PatternExpr)

**match**(*expr*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **expr** (Expression)
- **state** (MatchState)
- **ctx** (MatchCtx)

class angr.analyses.decompiler.known_patterns.dsl.**PatternStmt**

Bases: *PatternNode*

Base class of statement patterns.

**match**(*stmt*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **stmt** (Statement)
- **state** (MatchState)
- **ctx** (MatchCtx)

class angr.analyses.decompiler.known_patterns.dsl.**PAssign**

Bases: *PatternStmt*

Matches an Assignment statement.

**dst:** *PatternExpr*

**src:** *PatternExpr*

**optional:** bool = False

the statement may be absent from an occurrence

**Type**
fuzzy matching only

**weight:** float = 1.0

relative contribution to an occurrence's score

**Type**
fuzzy matching only

**match**(*stmt*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **stmt** (Statement)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*dst*, *src*, *, *optional=False*, *weight=1.0*)

**Parameters**

- **dst** (PatternExpr)
- **src** (PatternExpr)
- **optional** (*bool*)
- **weight** (*float*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.dsl.**PStore**

Bases: *PatternStmt*

Matches a Store statement. `size` is in bytes.

**addr:** *PatternExpr*

**value:** *PatternExpr*

**size:** int | None = None

**optional:** bool = False

the statement may be absent from an occurrence

**Type**
fuzzy matching only

**weight:** float = 1.0

relative contribution to an occurrence's score

**Type**
fuzzy matching only

**match**(*stmt*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **stmt** (Statement)

- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*addr*, *value*, *size=None*, ***, *optional=False*, *weight=1.0*)

**Parameters**

- **addr** (PatternExpr)
- **value** (PatternExpr)
- **size** (*int | None*)
- **optional** (*bool*)
- **weight** (*float*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.dsl.**PCallStmt**

Bases: *PatternStmt*

Matches a statement whose effect is a call.

Ailment has no Call statement: a call whose result is discarded is a `SideEffectStatement` wrapping the Call expression, and one whose result is kept is an ordinary `Assignment`. Both spellings are the same idiom, so both match; `dst`, when given, also constrains the assigned destination, which requires the assignment form.

**call:** *PCall*

**dst:** *PatternExpr* | None = None

**optional:** bool = False

the statement may be absent from an occurrence

**Type**
fuzzy matching only

**weight:** float = 1.0

relative contribution to an occurrence's score

**Type**
fuzzy matching only

**match**(*stmt*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **stmt** (Statement)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*call*, *dst=None*, ***, *optional=False*, *weight=1.0*)

**Parameters**

- **call** (PCall)
- **dst** (PatternExpr | *None*)

- **optional** (*bool*)
- **weight** (*float*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.dsl.**PCondJump**

Bases: *PatternStmt*

Matches a ConditionalJump, matching its condition expression.

**condition:** *PatternExpr*

**optional:** bool = False

the statement may be absent from an occurrence

**Type**
fuzzy matching only

**weight:** float = 1.0

relative contribution to an occurrence's score

**Type**
fuzzy matching only

**match**(*stmt*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **stmt** (Statement)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*condition*, *, *optional=False*, *weight=1.0*)

**Parameters**

- **condition** (PatternExpr)
- **optional** (*bool*)
- **weight** (*float*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.dsl.**PAnyStmt**

Bases: *PatternStmt*

Matches any single statement. The statement-level counterpart of *PAny*: a placeholder for "something happens here" whose exact form the pattern does not care about.

**optional:** bool = False

**weight:** float = 1.0

**match**(*stmt*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **stmt** (Statement)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*, *optional=False*, *weight=1.0*)

**Parameters**

- **optional** (*bool*)
- **weight** (*float*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.dsl.**PReturn**

Bases: *PatternStmt*

Matches a Return. `values` constrains the returned expressions, one pattern each; None matches a return of any arity.

**values:** tuple[*PatternExpr*, ...] | None = None

**optional:** bool = False

**weight:** float = 1.0

**match**(*stmt*, *state*, *ctx*)

**Return type**
*MatchState* | None

**Parameters**

- **stmt** (Statement)
- **state** (MatchState)
- **ctx** (MatchCtx)

**__init__**(*values=None*, *, *optional=False*, *weight=1.0*)

**Parameters**

- **values** (*tuple[PatternExpr, ...] | None*)
- **optional** (*bool*)
- **weight** (*float*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.dsl.**PStmtSeq**

Bases: *PatternStmt*

Matches a group of statements within one block. When `ordered` (the default), the statement patterns must match in order; with `allow_gaps`, unrelated statements may sit between the matched ones. When `ordered` is False, the statement patterns match statements of the block in any order (each pattern to a distinct statement), which suits idioms whose statement order the compiler chooses freely (e.g. list-link stores).

**stmts:** `tuple[PatternStmt, ...]`

**allow_gaps:** `bool = True`

**ordered:** `bool = True`

**max_gap:** `int = 8`

How many unmatched statements may sit between two matched ones. Without a bound the scan runs to the end of the block from every statement it could start at, quadratic per block per template, and finds nothing: an idiom's statements are adjacent apart from what the scheduler interleaved, which is a handful of instructions rather than a basic block.

**__init__**(*stmts*, *allow_gaps=True*, *ordered=True*, *max_gap=8*)

**Parameters**

- **stmts** (*tuple[PatternStmt, ...]*)
- **allow_gaps** (*bool*)
- **ordered** (*bool*)
- **max_gap** (*int*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.dsl.**PBlockPat**

Bases: *PatternNode*

A labeled block of statements in a multi-block pattern graph. An empty `stmts` sequence matches any block (structure alone identifies it).

**label:** `str`

**stmts:** *PStmtSeq*

**__init__**(*label*, *stmts*)

**Parameters**

- **label** (*str*)
- **stmts** (PStmtSeq)

**Return type**
None

class angr.analyses.decompiler.known_patterns.dsl.**PGraphPat**

Bases: *PatternNode*

A multi-block pattern: labeled blocks connected by edges.

`blocks` maps a label to its *PBlockPat*. `edges` are `(src_label, dst_label)` pairs; a destination label that does not appear in `blocks` denotes an external successor, a region exit that becomes the Outliner frontier. `entry` is the label of the single entry block. Captures unify across all blocks (one bindings environment).

**blocks:** dict[str, *PBlockPat*]

**edges:** Sequence[tuple[str, str]]

**entry:** str

**property external_labels:** set[str]

**__init__**(*blocks*, *edges*, *entry*)

**Parameters**

- **blocks** (*dict[str, PBlockPat]*)
- **edges** (*Sequence[tuple[str, str]]*)
- **entry** (*str*)

**Return type**
None

angr.analyses.decompiler.known_patterns.dsl.**LeafStmt** = **angr.analyses.decompiler.known_patterns.dsl.PAssign | angr.analyses.decompiler.known_patterns.dsl.PStore | angr.analyses.decompiler.known_patterns.dsl.PCallStmt | angr.analyses.decompiler.known_patterns.dsl.PCondJump | angr.analyses.decompiler.known_patterns.dsl.PReturn | angr.analyses.decompiler.known_patterns.dsl.PAnyStmt**

The statement patterns that stand for one concrete statement, and so are the ones a fuzzy occurrence can score, skip or weight.

angr.analyses.decompiler.known_patterns.dsl.**iter_stmt_patterns**(*node*)

Every leaf statement pattern under node, in pattern order.

**Return type**
Iterator[*PAssign* | *PStore* | *PCallStmt* | *PCondJump* | *PReturn* | *PAnyStmt*]

**Parameters**
**node** (PatternNode)

angr.analyses.decompiler.known_patterns.dsl.**has_fuzzy_nodes**(*node*)

Whether node can only be matched by the fuzzy matcher.

An optional statement has no meaning to the exact matcher, which either finds every statement pattern or fails; a pattern carrying one has to be kept away from it rather than silently matched as if the statement were required.

**Return type**
bool

**Parameters**
**node** (PatternNode)

angr.analyses.decompiler.known_patterns.dsl.**pattern_anchor_key**(*node*)

A cheap discriminator of the pattern root, used to prune candidate patterns at each expression position: `(ail kind, op or None)`.

Returns None when the root is not discriminating (PAny/PChoice/...), in which case the pattern must be attempted everywhere.

**Return type**
tuple[str, str | None] | None

**Parameters**
**node** (PatternNode)

angr.analyses.decompiler.known_patterns.dsl.**pattern_index_keys**(*node*)

Every `(ail kind, op or None, constant operand or None)` an occurrence of `node` can start with; None when the root is not discriminating.

Finer than *pattern_anchor_key()* in three ways. A set-valued op is expanded into one key per op rather than dropped to "any op". A PChoice is the union of its alternatives' keys, not "anywhere" unless one alternative truly is. And a binary op with a PConst operand whose values are enumerable (`value` or `values`) carries each such value as a third component: a PConst only matches a literal Const, so a `Mul(x, magic)` pattern need not be tried at a multiply by any other constant. The generated `std::vector<T>::size` family is a thousand such patterns keyed on `Mul`, and without this every multiply in a function tried all of them.

**Return type**
list[tuple[str, str | None, int | None]] | None

**Parameters**
**node** (PatternNode)

angr.analyses.decompiler.known_patterns.dsl.**expr_const_operands**(*expr*)

The literal constants among a binary op's operands (through Converts), for the index lookup.

**Return type**
tuple[int, ...]

**Parameters**
**expr** (Expression)

angr.analyses.decompiler.known_patterns.dsl.**stmt_pattern_anchor_key**(*node*)

The discriminator of a *statement* pattern's first statement.

Statement patterns are anchored at every statement of every block and then scan forward, so trying one that cannot possibly match is the expensive kind of waste. The key is the statement kind plus the anchor key of the expression that carries the pattern's shape (an assignment's source, a store's value), which is what separates `t = *a` (a swap) from the assignments that make up most of a block.

**Return type**
tuple[str, tuple[str, str | None] | None] | None

**Parameters**
**node** (PatternNode)

angr.analyses.decompiler.known_patterns.dsl.**stmt_anchor_key**(*stmt*)

The anchor key of a concrete AIL statement, for pruning.

**Return type**
tuple[str, tuple[str, str | None] | None]

**Parameters**
**stmt** (Statement)

angr.analyses.decompiler.known_patterns.dsl.**expr_anchor_key**(*expr*)

The anchor key of a concrete AIL expression, for pruning.

**Return type**
tuple[str, str | None]

**Parameters**
**expr** (Expression)

### angr.analyses.decompiler.known_patterns.edit

Edit a pattern the way a visual editor does: by node, with undo.

Pattern nodes are frozen, so an edit rebuilds the spine from the root down to the node it touches and leaves everything else shared. A node is addressed by its *path*, the sequence of field names, tuple indices and block labels that leads to it from the root, which is what a UI holds on to across rebuilds.

angr.analyses.decompiler.known_patterns.edit.**NodePath**

field names, tuple indices, block labels

**Type**
how a node is reached from the pattern root

alias of tuple[str | int, ...]

angr.analyses.decompiler.known_patterns.edit.**LEAF_MODES = ('required', 'optional', 'wildcard')**

the three ways a leaf statement takes part in matching

**class** angr.analyses.decompiler.known_patterns.edit.**PatternEditor**

Bases: object

A KnownPattern under edit.

**__init__**(*pattern*)

**Parameters**
**pattern** (KnownPattern)

**node_at**(*path*)

**Return type**
*PatternNode*

**Parameters**
**path** (*tuple[str | int, ...]*)

**restorable**(*path*)

The most recent form the wildcard at path had before it became one, from the edit history, or None if it has always been a wildcard (as a generator-made one is).

**Return type**
*PatternNode* | None

**Parameters**
**path** (*tuple[str | int, ...]*)

**children**(*path*)

The pattern nodes directly under the node at path, in field order.

**Return type**
list[tuple[tuple[str | int, ...], *PatternNode*]]

**Parameters**
**path** (*tuple[str | int, ...]*)

**leaves**()

Every leaf statement with its path, in the order the matcher aligns them.

**Return type**
list[tuple[tuple[str | int, ...], *PAssign* | *PStore* | *PCallStmt* | *PCondJump* | *PReturn* | *PAnyStmt*]]

**static leaf_mode**(*leaf*)

**Return type**
str

**Parameters**
**leaf** (PAssign | PStore | PCallStmt | PCondJump | PReturn | PAnyStmt)

**replace_node**(*path*, *new_node*)

**Return type**
None

**Parameters**

- **path** (*tuple[str | int, ...]*)
- **new_node** (PatternNode)

**set_leaf_mode**(*path*, *mode*)

`required` or `optional` keep the statement's shape; `wildcard` drops it for a PAnyStmt that keeps the weight and optionality. Leaving `wildcard` brings back the shape the statement had before, when the history has one.

**Return type**
None

**Parameters**

- **path** (*tuple[str | int, ...]*)
- **mode** (*str*)

**restore_node**(*path*)

Put back the form the wildcard at `path` had before it became one, as one undoable edit; a statement keeps its current weight and optionality. Returns whether it could.

**Return type**
bool

**Parameters**
**path** (*tuple[str | int, ...]*)

**set_leaf_weight**(*path*, *weight*)

**Return type**
None

**Parameters**

- **path** (*tuple[str | int, ...]*)
- **weight** (*float*)

**set_expr_wildcard**(*path*)

Replace an expression node by PAny, keeping its capture name and width if it had them.

**Return type**
None

**Parameters**
**path** (*tuple[str | int, ...]*)

**set_const**(*path*, *value*, *bits=None*, *, *symbol=None*)

Pin a constant to a value, or to a symbol's address in whatever binary is matched. One or the other: a symbol names the value, so giving both is refused.

**Return type**
None

**Parameters**

- **path** (*tuple[str | int, ...]*)
- **value** (*int | None*)
- **bits** (*int | None*)
- **symbol** (*str | None*)

**set_vvar**(*path*, *bits*, *categories*)

**Return type**
None

**Parameters**

- **path** (*tuple[str | int, ...]*)
- **bits** (*int | None*)
- **categories** (*frozenset | None*)

**set_load_size**(*path*, *size*)

**Return type**
None

**Parameters**

- **path** (*tuple[str | int, ...]*)
- **size** (*int | None*)

**set_ops**(*path*, *ops*)

**Return type**
None

**Parameters**

- **path** (*tuple[str | int, ...]*)
- **ops** (*str | frozenset[str]*)

**loosen_constants**()

Drop the value of every pinned constant, as one undoable edit. Copies of an idiom that differ only in their constants, a decryption loop's keys and sizes, say, are exactly what a fuzzy pattern is for, and pinning them is what a lifted pattern starts out doing. Returns how many constants were loosened.

**Return type**
int

**cut_depth**(*max_depth=5*)

Replace every expression deeper than `max_depth` below its statement by a wildcard, as one undoable edit. Shape search is cut at that depth, so anything below it never affects where an occurrence is found; it only bites at verification, where two copies of an idiom that differ in how they spell a deep subexpression part ways. Returns how many subtrees were cut.

**Return type**
int

**Parameters**
**max_depth** (*int*)

**loosen_interior_captures**()

Drop the names of interior captures (the `_t*` ones the generator gives values defined inside the selection), as one undoable edit. A name ties every use to one variable; a copy that routes the same value through another register then fails to verify. Parameters keep their names. Returns how many captures were loosened.

**Return type**
int

**set_call_name**(*call_name*)

**Return type**
None

**Parameters**
**call_name** (*str*)

**set_name**(*name*)

**Return type**
None

**Parameters**
**name** (*str*)

**set_display_name**(*display_name*)

**Return type**
None

**Parameters**
**display_name** (*str*)

**set_returnty**(*returnty*)

**Return type**
None

**Parameters**
**returnty** (*str | CppRef | None*)

**set_param_type**(*capture*, *typeref*)

**Return type**
None

**Parameters**

- **capture** (*str*)
- **typeref** (*str | CppRef | None*)

**add_param**(*capture*, *typeref=None*)

**Return type**
None

**Parameters**

- **capture** (*str*)
- **typeref** (*str | CppRef | None*)

**remove_param**(*capture*)

**Return type**
None

**Parameters**
**capture** (*str*)

**property can_undo: bool**

**undo**()

**Return type**
bool

**to_dict**()

**Return type**
dict[str, Any]

**classmethod from_dict**(*data*)

**Return type**
*PatternEditor*

**Parameters**
**data** (*dict[str, Any]*)

angr.analyses.decompiler.known_patterns.edit.**describe**(*node*)

A short label for a node: what it is and what it constrains.

**Return type**
str

**Parameters**
**node** (PatternNode)

### angr.analyses.decompiler.known_patterns.finder

KnownPatternFinder: find occurrences of KnownPatterns in a Clinic AIL graph and outline them into calls via the Outliner analysis.

**exception** angr.analyses.decompiler.known_patterns.finder.**UnsupportedOutlineError**

Bases: Exception

Raised when a match cannot be safely outlined (e.g. side-effecting statements interleave with the matched span, or the recovered callee interface does not agree with the pattern's declared parameters).

class angr.analyses.decompiler.known_patterns.finder.**KnownPatternMatch**

Bases: object

One occurrence of a KnownPattern in an AIL graph.

For expression-level matches, the boundary is `consumed_stmt_idxs` (statements wholly owned by the match, e.g. chased definitions) plus `expr_path` (the location of the matched sub-expression inside the anchor statement). For statement-sequence matches, `stmt_span` holds the ordered matched statement indices (the anchor is the first) and `matched_expr` is None.

`duplicated_stmt_idxs` holds chased definitions that are copied into the outlined region instead of moved: the originals stay where they are (other code still uses them) and the copies make the pattern's captured values the region's live-ins. It is always disjoint from `consumed_stmt_idxs`.

`recomputed_defs` does the same for definitions that live in *another* block (a CSE'd value, possibly reaching the anchor through a phi): the expression is pure, so the region recomputes it from the captured operands.

**pattern:** *KnownPattern*

**block_loc:** tuple[int, int]

**anchor_stmt_idx:** int

**expr_path:** tuple[tuple[str, int | None], ...]

**consumed_stmt_idxs:** frozenset[int]

**captures:** dict[str, *Expression*]

**matched_expr:** *Expression* | None

**duplicated_stmt_idxs:** frozenset[int] = frozenset({})

**recomputed_defs:** tuple[tuple[int, *Expression*], ...] = ()

**base_aliases:** tuple[tuple[int, int, int], ...] = ()

**stmt_span:** tuple[int, ...] | None = None

**block_map:** dict[str, tuple[int, int]] | None = None

**consumed_by_block:** dict[tuple[int, int], frozenset[int]] | None = None

**frontier_locs:** frozenset[tuple[int, int]] | None = None

**__init__**(*pattern*, *block_loc*, *anchor_stmt_idx*, *expr_path*, *consumed_stmt_idxs*, *captures*, *matched_expr*, *duplicated_stmt_idxs=frozenset({})*, *recomputed_defs=()*, *base_aliases=()*, *stmt_span=None*, *block_map=None*, *consumed_by_block=None*, *frontier_locs=None*)

**Parameters**

- **pattern** (KnownPattern)
- **block_loc** (*tuple[int, int]*)
- **anchor_stmt_idx** (*int*)
- **expr_path** (*tuple[tuple[str, int | None], ...]*)
- **consumed_stmt_idxs** (*frozenset[int]*)
- **captures** (*dict[str, Expression]*)
- **matched_expr** (Expression | *None*)

- **duplicated_stmt_idxs** (*frozenset[int]*)
- **recomputed_defs** (*tuple[tuple[int, Expression], ...]*)
- **base_aliases** (*tuple[tuple[int, int, int], ...]*)
- **stmt_span** (*tuple[int, ...] | None*)
- **block_map** (*dict[str, tuple[int, int]] | None*)
- **consumed_by_block** (*dict[tuple[int, int], frozenset[int]] | None*)
- **frontier_locs** (*frozenset[tuple[int, int]] | None*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.finder.**OutlineResult**

Bases: object

The outcome of outlining one KnownPatternMatch.

**graph:** DiGraph

**match:** *KnownPatternMatch*

**call_stmt:** *Statement*

**child_func:** *Function* | None

**child_graph:** DiGraph | None

**child_funcargs:** list[*VirtualVariable*]

**__init__**(*graph*, *match*, *call_stmt*, *child_func*, *child_graph*, *child_funcargs*)

**Parameters**

- **graph** (*DiGraph*)
- **match** (KnownPatternMatch)
- **call_stmt** (Statement)
- **child_func** (Function | *None*)
- **child_graph** (*DiGraph* | *None*)
- **child_funcargs** (*list[VirtualVariable]*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.finder.**KnownPatternFinder**

Bases: *Analysis*

Finds occurrences of KnownPatterns in a Clinic AIL graph.

The graph to match on is the final (SSA-form) Clinic graph, i.e. `decompiler.ail_graph` / `clinic.cc_graph`. Matches are reported in `self.matches`; *outline()* turns a match into a synthesized call by invoking the Outliner analysis on a copy of the graph.

**MAX_REMOTE_CHASE_DEPTH = 6**

__init__(*func*, *ail_graph*, *patterns=None*, *chase_defs=True*, *chase_remote_defs=True*, *skip_conversions=True*, *vvar_id_start=48879*, *block_addr_start=2864381952*, *ail_manager=None*, *force_patterns=None*)

patterns may be pattern templates (KnownPatternTemplate) and/or already-concrete KnownPatterns; templates are instantiated for this binary's PatternContext. When None, the registry is used, filtered down to the templates that are enabled for this target: default-on ones, ones named by force_patterns, and ones whose gate opens (see *gating*).

force_patterns is the user's force-enable selection, "all" or an iterable of template names / call names, and is only consulted when patterns is None (an explicit pattern list is already a selection).

**Parameters**

- **func** (Function)
- **ail_graph** (*DiGraph*)
- **patterns** (*Iterable[object] | None*)
- **chase_defs** (*bool*)
- **chase_remote_defs** (*bool*)
- **skip_conversions** (*bool*)
- **vvar_id_start** (*int*)
- **block_addr_start** (*int*)
- **force_patterns** (*str | Iterable[str] | None*)

**matches:** list[*KnownPatternMatch*]

call_target_names(*call*)

Public face of _resolve_call_target(), for the outliner's clean-up of calls a pattern declared pure.

**Return type**
frozenset[str]

**Parameters**
**call** (Call)

apply_matches(*matches*, *ail_graph*)

Apply as many of matches as possible, batching where it matters.

Applying one match at a time is fine until several of them interleave in one block, which is exactly what consecutive field swaps do:

**t1 = x->b; t2 = y->b; y->b = t1; x->b = t2;**
^ the next field's load sits in this one's gap

Rewrite the first and the second's statements have moved; rewrite it anyway and the third now has an opaque call sitting in its gap, which no disjointness test will let it move across. So the void statement-span matches of a block, which the finder has already checked do not conflict, are spliced in together, against the statement indices they were found at. Everything else keeps the one-at-a-time path.

Returns the new graph and the ids of the matches that were applied.

**Return type**
tuple[DiGraph, set[int]]

**Parameters**

- **matches** (*list[KnownPatternMatch]*)

- **ail_graph** (*DiGraph*)

**outline**(*match*, *ail_graph=None*)

Outline one match: split the anchor block so the matched span forms its own block, invoke the Outliner analysis on it, and rewrite the synthesized callsite into the pattern's call. Operates on (and returns) a copy; neither `self._graph` nor `ail_graph` is mutated.

**Return type**
*OutlineResult*

**Parameters**

- **match** (KnownPatternMatch)
- **ail_graph** (*DiGraph | None*)

**MAX_LIFTED_EXPR_NODES = 8**

Node budget for a lifted parameter expression; see _is_liftable.

**outline_at**(*location*, *pattern*, *ail_graph*)

Find `pattern` at `location` (`(block_addr, block_idx)` or `(block_addr, block_idx, stmt_idx)`) in `ail_graph` and outline it.

**Return type**
*OutlineResult*

**Parameters**

- **location** (*tuple[int, int] | tuple[int, int | None, int]*)
- **pattern** (KnownPattern)
- **ail_graph** (*DiGraph*)

### angr.analyses.decompiler.known_patterns.gating

Criteria gates: per-target (and per-function) enablement for pattern templates.

A *KnownPatternTemplate* carries static applicability filters (arch / language / runtime / platform) and a boolean `default_enabled`. Many idioms are opt-in because their shape is too generic to ship on every binary: `Load(p) == 0` is a list-emptiness test in a kernel module and a null check everywhere else.

A gate is the third channel: it lets an opt-in template say "turn me on when this evidence is present". Two kinds of evidence are modelled:

- target evidence (*TargetGate*): a fact about the binary as a whole, derived once into the *PatternContext*: this is a Linux kernel module, this is a Windows kernel-mode driver. Cheap, exact, and evaluated before any matching happens.
- corroboration (*CorroboratedBy*): another, unambiguous pattern already matched in the same function. This is what converts "too generic to ship" into "safe here": `Load(Load(s))` is meaningless on its own, but in a function where `std::string::length` (a load at the string's size offset) or `std::string::capacity` (the self-referential SSO select) already matched, the object really is a `std::string` and the load really is `front()`.

Corroboration needs the match results, so it is resolved by *KnownPatternFinder* in a second matching stage: the finder matches with the ungated set, collects the evidence, re-evaluates the gates that asked for it, and, only if that opens something, matches again with the enlarged set. Gates that do not need evidence are resolved up front.

A gate can only open an opt-in template; it never disables a default-on one.

class angr.analyses.decompiler.known_patterns.gating.**GateContext**

Bases: object

Everything a gate may look at.

**Variables**

- **ctx** (*PatternContext*) – The target's *PatternContext* (arch, platform, C++ runtime, and the binary-evidence facts).
- **project** (*Project* | None) – The Project, for gates that need to look past the context.
- **evidence** (frozenset[str]) – Names and call names of the patterns established in the function currently being matched: both the patterns that matched in the first stage and the known-pattern calls already present in the graph (outlined by an earlier round). Empty when gates are evaluated outside a function.

**ctx:** *PatternContext*

**project:** *Project* | None = None

**evidence:** frozenset[str] = frozenset({})

**with_evidence**(*evidence*)

**Return type**
*GateContext*

**Parameters**
**evidence** (*Iterable[str]*)

**__init__**(*ctx*, *project=None*, *evidence=frozenset({})*)

**Parameters**

- **ctx** (PatternContext)
- **project** (Project | *None*)
- **evidence** (*frozenset[str]*)

**Return type**
None

class angr.analyses.decompiler.known_patterns.gating.**PatternGate**

Bases: object

Base class for template gates. Instances are callables so that a gate can be used anywhere a Callable[[GateContext], bool] is expected.

**opens**(*gctx*)

**Return type**
bool

**Parameters**
**gctx** (GateContext)

**property requires_evidence:** bool

Whether this gate can only be decided once the function's matches are known. Such gates are evaluated a second time by the finder.

**property label:** str

**__init__**()

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.gating.**TargetGate**

Bases: *PatternGate*

Opens when a predicate over the target's PatternContext holds.

The predicate reads facts that were derived once from the loaded binary, so evaluating it is free and its result is the same for every function.

**name:** str

**predicate:** Callable[[*PatternContext*], bool]

**opens**(*gctx*)

**Return type**
bool

**Parameters**
**gctx** (GateContext)

**property label:** str

**__init__**(*name*, *predicate*)

**Parameters**

- **name** (*str*)
- **predicate** (Callable[[PatternContext], *bool*])

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.gating.**CorroboratedBy**

Bases: *PatternGate*

Opens in a function where at least one of witnesses already matched.

Witnesses are given as template name or call_name values; the finder puts both spellings of every established pattern into the evidence set.

**witnesses:** frozenset[str]

**opens**(*gctx*)

**Return type**
bool

**Parameters**
**gctx** (GateContext)

**property requires_evidence:** bool

Whether this gate can only be decided once the function's matches are known. Such gates are evaluated a second time by the finder.

**property label:** str

**__init__**(*witnesses*)

**Parameters**
**witnesses** (*frozenset[str]*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.gating.**AnyOf**

Bases: *PatternGate*

Opens when any sub-gate opens.

**gates:** tuple[*PatternGate*, ...]

**opens**(*gctx*)

**Return type**
bool

**Parameters**
**gctx** (GateContext)

**property requires_evidence:** bool

Whether this gate can only be decided once the function's matches are known. Such gates are evaluated a second time by the finder.

**property label:** str

**__init__**(*gates=<factory>*)

**Parameters**
**gates** (*tuple[PatternGate, ...]*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.gating.**AllOf**

Bases: *PatternGate*

Opens when every sub-gate opens.

**gates:** tuple[*PatternGate*, ...]

**opens**(*gctx*)

**Return type**
bool

**Parameters**
**gctx** (GateContext)

**property requires_evidence:** bool

Whether this gate can only be decided once the function's matches are known. Such gates are evaluated a second time by the finder.

**property label:** str

**__init__**(*gates=<factory>*)

**Parameters**
**gates** (*tuple[PatternGate, ...]*)

**Return type**
None

angr.analyses.decompiler.known_patterns.gating.**corroborated_by**(**witnesses*)

A gate that opens in a function where one of `witnesses` matched.

**Return type**
*CorroboratedBy*

**Parameters**
**witnesses** (*str*)

**class** angr.analyses.decompiler.known_patterns.gating.**CorroboratedByPattern**

Bases: *PatternGate*

Opens where evidence matching a *regex* was established.

`CorroboratedBy` takes a fixed list of witness names, which no longer scales: families are generated per element size, so "any std::vector<T>::size" is five hundred names. This matches the evidence set instead.

**regex:** `str`

**opens**(*gctx*)

**Return type**
bool

**Parameters**
**gctx** (GateContext)

**property requires_evidence:** `bool`

Whether this gate can only be decided once the function's matches are known. Such gates are evaluated a second time by the finder.

**property label:** `str`

**__init__**(*regex*)

**Parameters**
**regex** (*str*)

**Return type**
None

angr.analyses.decompiler.known_patterns.gating.**corroborated_by_pattern**(*regex*)

A gate that opens in a function where evidence matching `regex` was established.

**Return type**
*CorroboratedByPattern*

**Parameters**
**regex** (*str*)

angr.analyses.decompiler.known_patterns.gating.**any_of**(**gates*)

**Return type**
*AnyOf*

**Parameters**
**gates** (PatternGate)

angr.analyses.decompiler.known_patterns.gating.**all_of**(**gates*)

**Return type**
*AllOf*

**Parameters**
**gates** (PatternGate)

angr.analyses.decompiler.known_patterns.gating.**LINUX_KERNEL** = **TargetGate(name='linux-kernel-object', predicate=<function <lambda>>)**

it carries the module metadata sections, or exports symbols through __ksymtab.

**Type**
The binary is a Linux kernel module (or the kernel image itself)

**Parameters**
**gctx** (GateContext)

**Return type**
bool

angr.analyses.decompiler.known_patterns.gating.**WINDOWS_KERNEL_DRIVER** = **TargetGate(name='windows-kernel-driver', predicate=<function <lambda>>)**

it imports ntoskrnl/hal/a kernel -mode port or miniport library rather than the user-mode Win32 DLLs.

**Type**
The binary is a Windows kernel-mode driver

**Parameters**
**gctx** (GateContext)

**Return type**
bool

angr.analyses.decompiler.known_patterns.gating.**KERNEL_TARGET** = **AnyOf(gates=(TargetGate(name='linux-kernel-object', predicate=<function <lambda>>), TargetGate(name='windows-kernel-driver', predicate=<function <lambda>>)))**

Either of the two kernel targets, the audience for the intrusive doubly-linked-list idioms, which `list_head` and `LIST_ENTRY` share.

**Parameters**
**gctx** (GateContext)

**Return type**
bool

### angr.analyses.decompiler.known_patterns.generator

PatternGenerator: build a KnownPattern from a decompilation text selection.

This is the inverse of `KnownPatternFinder`. Given a range of the generated C source (`Decompiler.codegen`) and a target call, it resolves the selection back to AIL statements/expressions and emits the corresponding DSL pattern:

- an expression selection (a sub-expression of one statement) becomes a *PatternExpr* tree;
- a straight-line statement selection (statements of one basic block) becomes a *PStmtSeq*;
- a selection spanning several basic blocks becomes a *PGraphPat* (requires the finder's `ail_graph` for the block/edge structure).

Text offsets are resolved through the codegen position maps (`map_pos_to_node` / `ailexpr2cnode` / `cnode2ailexpr`); the rendered AIL objects are `.likes()`-equal to the finder's graph objects, so a generated pattern re-matches via `KnownPatternFinder` on the same `ail_graph` (the round-trip is the acceptance test).

angr.analyses.decompiler.known_patterns.generator.**stmt_ins_addrs**(*stmt*)

The instruction addresses a statement and its subexpressions carry.

**Return type**
set[int]

**Parameters**
**stmt** (Statement)

**exception** angr.analyses.decompiler.known_patterns.generator.**PatternGenerationError**

Bases: Exception

Raised when a selection cannot be turned into a KnownPattern (ambiguous, unsupported, or inconsistent with the given arguments).

**class** angr.analyses.decompiler.known_patterns.generator.**PatternGenerator**

Bases: object

Generate a `KnownPattern` from a text selection in `codegen.text`.

**Parameters**

- **codegen** – the `Decompiler.codegen` (a `CStructuredCodeGenerator`).
- **ail_graph** (DiGraph | None) – the graph the generated pattern will be matched against (`Decompiler.ail_graph`). Required for multi-block (control-flow-spanning) selections; optional otherwise.

**__init__**(*codegen*, *ail_graph=None*)

**Parameters**
**ail_graph** (*networkx.DiGraph | None*)

**vvar_id_at**(*offset*)

The AIL vvar id of the variable rendered at `offset`, or None.

**Return type**
int | None

**Parameters**
**offset** (*int*)

**offset_of**(*needle*, *start=0*)

Convenience: the offset of `needle` in the rendered text.

**Return type**
int

**Parameters**

- **needle** (*str*)
- **start** (*int*)

**generate**(*start_offset*, *end_offset*, *call_name*, *arg_offsets*, ***, *name=None*, *display_name=None*, *returnty=None*, *param_types=None*, *const_arg_offsets=()*, *arches=None*, *platforms=None*, *binary_guard=None*, *default_enabled=False*)

**Return type**
*KnownPattern*

**Parameters**

- **start_offset** (*int*)
- **end_offset** (*int*)
- **call_name** (*str*)
- **arg_offsets** (*Sequence[int]*)
- **name** (*str | None*)
- **display_name** (*str | None*)
- **returnty** (*TypeRef | None*)
- **param_types** (*Sequence[TypeRef | None] | None*)
- **const_arg_offsets** (*Sequence[int]*)
- **arches** (*tuple[str, ...] | None*)
- **platforms** (*tuple[str, ...] | None*)
- **default_enabled** (*bool*)

**generate_pattern**(*start_offset*, *end_offset*, *call_name*, ***, *name=None*, *display_name=None*, *returnty=None*, *param_types=None*)

A pattern for the fuzzy matcher from the statements the selection covers.

Unlike *generate()*, this asks nothing of the user beyond the span: every whole statement inside it becomes a leaf, a statement the DSL cannot express becomes a `PAnyStmt` rather than an error, and the call's parameters are the variables the statements read without defining, in the order they are first read. Constants stay exact; the editor is where they are loosened.

**Return type**
*KnownPattern*

**Parameters**

- **start_offset** (*int*)
- **end_offset** (*int*)
- **call_name** (*str*)
- **name** (*str | None*)
- **display_name** (*str | None*)
- **returnty** (*TypeRef | None*)
- **param_types** (*Sequence[TypeRef | None] | None*)

**generate_pattern_from_statements**(*stmts*, *call_name*, ***, *name=None*, *display_name=None*, *returnty=None*, *param_types=None*)

*generate_pattern()* for a caller that already holds the statements, in order.

**Return type**
*KnownPattern*

**Parameters**

- **stmts** (*Sequence[Statement]*)

- **call_name** (*str*)
- **name** (*str | None*)
- **display_name** (*str | None*)
- **returnty** (TypeRef | *None*)
- **param_types** (*Sequence[TypeRef | None] | None*)

### angr.analyses.decompiler.known_patterns.kernel_err

Linux kernel <linux/err.h> error-pointer idioms.

IS_ERR(p) tests (unsigned long)p >= (unsigned long)-MAX_ERRNO; the threshold is derived from the context's word width, so one definition covers 32- and 64-bit.

gcc emits the test in four different shapes depending on where it lands, and a pattern that covers only one of them silently misses most real code: the literal >= THR, the strength-reduced > THR-1 (the value form at -O2), and the operand-swapped <= / < forms (the branch-condition form). All four are matched. The comparison must be unsigned (a signed compare against the same constant is an unrelated test), which is checked in `where` because the DSL does not model `BinaryOp.signed`.

PTR_ERR and ERR_PTR are pure casts that compile to a bare register move and leave no residue at all, so there is nothing to match and they are deliberately absent.

Opt-in: these are kernel idioms, and renaming a comparison to IS_ERR() in a user-space binary would be misleading even though the threshold constant is in practice unique to err.h. Calibrated against tests/x86_64/decompiler/known_patterns_kernel_macros (gcc -O2).

### angr.analyses.decompiler.known_patterns.layouts

Runtime-specific struct layout offsets for the STL container patterns.

Where a field offset is simply the n-th pointer word it is `ctx.word(n)` (scales with the architecture). Where a runtime differs in a less regular way, the conditional lives here: the MSVC std::string keeps its size behind a fixed 16-byte SSO buffer union while libstdc++ keeps it one word past the data pointer.

angr.analyses.decompiler.known_patterns.layouts.**string_data_offset**(*_ctx*)

Offset of the character data pointer (_M_p / _Bx). 0 in both runtimes.

**Return type**
int

**Parameters**
**_ctx** (PatternContext)

angr.analyses.decompiler.known_patterns.layouts.**string_size_offset**(*ctx*)

Offset of the length field (_M_string_length / _Mysize).

**Return type**
int

**Parameters**
**ctx** (PatternContext)

angr.analyses.decompiler.known_patterns.layouts.**string_capacity_offset**(*ctx*)

libstdc++: offset of the { _M_local_buf[16] | _M_allocated_capacity } union, immediately after _M_p and _M_string_length. Only libstdc++ needs it: the MSVC STL keeps _Myres in a plain field and its capacity() is a bare load, so no pattern here asks for the MSVC offset.

**Return type**
int

**Parameters**
**ctx** (PatternContext)

angr.analyses.decompiler.known_patterns.layouts.**vector_begin_offset**(*ctx*)

**Return type**
int

**Parameters**
**ctx** (PatternContext)

angr.analyses.decompiler.known_patterns.layouts.**vector_end_offset**(*ctx*)

**Return type**
int

**Parameters**
**ctx** (PatternContext)

angr.analyses.decompiler.known_patterns.layouts.**vector_cap_offset**(*ctx*)

**Return type**
int

**Parameters**
**ctx** (PatternContext)

angr.analyses.decompiler.known_patterns.layouts.**list_next_offset**(*ctx*)

**Return type**
int

**Parameters**
**ctx** (PatternContext)

angr.analyses.decompiler.known_patterns.layouts.**list_prev_offset**(*ctx*)

**Return type**
int

**Parameters**
**ctx** (PatternContext)

### angr.analyses.decompiler.known_patterns.libm_bits

libm floating-point bit-twiddling idioms (fabs / -x / copysign / isnan / isinf).

Every one of these "functions" is a compiler intrinsic: on x86-64 with SSE they become a single `andpd` / `xorpd` / `andnpd` / `ucomisd` against a sign-mask constant kept in `.rodata`. angr's `constant_derefs` peephole folds the rip-relative mask load into a `Const`, so what reaches the AIL is a plain integer bit operation on the raw float bits: `fabs(x)` is `x & 0x7fffffffffffffff`, unreadable unless it is named again.

Two AIL spellings show up for the SSE operand, depending on whether the 128-bit vector op survived narrowing:

- narrowed: `BinaryOp(And, vvar_0, 0x7fffffffffffffff<64>)`
- unnarrowed: `BinaryOp(Xor, Conv(64->128, vvar_0), 0x8000000000000000<128>)` under an `Extract(..., 64bits@0)`

_sse_operand accepts both and always captures the underlying vvar, which the Outliner requires (call parameters must bind VirtualVariables).

Intel-SSE specific (the mask widths are fixed by the FP format, not by the pointer size), so these are not word-scaled. Calibrated against tests/x86_64/decompiler/known_patterns_libm_bits (gcc -O2 -fno-tree-vectorize).

### angr.analyses.decompiler.known_patterns.linked_list

Doubly-linked-list idioms shared by Windows LIST_ENTRY (Flink/Blink) and Linux kernel list_head (next/prev): the same two-pointer layout, so one set of templates matches both WDK drivers and kernel/Boost-intrusive code.

Covers the empty test, head init, unlink (RemoveEntryList / __list_del_entry), head/tail insertion (InsertHeadList / list_add, InsertTailList / list_add_tail), the two unlink supersets the kernel actually calls, list_del (unlink + LIST_POISON1/2 stores) and list_del_init (unlink + re-init), and the hlist_del diamond. The supersets rely on the finder preferring the largest match, so they win over the bare unlink they contain.

The link offsets are word-scaled from the PatternContext, so the same definitions work on 32- and 64-bit. Opt-in (genericish C idioms). Calibrated against tests/x86_64/windows/known_patterns_wdk_list.exe and tests/x86_64/decompiler/known_patterns_linux_list (both -O2, SLP off); the compiler orders the link loads/stores freely, so the multi-statement idioms use unordered statement-set matching (hlist_del excepted: PGraphPat block bodies only support ordered matching).

hlist_add_head is absent on purpose: its last two stores land in the diamond's join block, and _outline_graph requires every interior block to be fully consumed, so the idiom cannot be outlined without misrepresenting it.

### angr.analyses.decompiler.known_patterns.pattern

KnownPattern: declarative metadata around a pattern-AST.

A *KnownPattern* couples a structural pattern (see *dsl*) with the information needed to turn a match into a synthesized call: the call name, the ordered parameters (mapping captures to call arguments and types), the return type, and applicability guards.

**class** angr.analyses.decompiler.known_patterns.pattern.**CppRef**

Bases: object

A reference to a C++ class type registered in the cpp::std SimTypeCollection, keyed by its unique (mangled-style) name.

**unique_name:** *str*

**ptr:** *bool* = **True**

**resolve**(*arch*)

**Return type**
*SimType* | None

**Parameters**
**arch** (*archinfo.Arch*)

**__init__**(*unique_name*, *ptr=True*)

**Parameters**

- **unique_name** (*str*)
- **ptr** (*bool*)

**Return type**
None

angr.analyses.decompiler.known_patterns.pattern.**resolve_typeref**(*ref*, *arch*)

Resolve a TypeRef into a SimType: a C declaration string is parsed with `parse_type`; a CppRef is looked up in the cpp::std collection.

**Return type**
*SimType* | None

**Parameters**

- **ref** (TypeRef | *None*)
- **arch** (*archinfo.Arch*)

**class** angr.analyses.decompiler.known_patterns.pattern.**PatternParam**

Bases: object

One parameter of the synthesized call.

**Variables**

- **capture** (str) – Name of the pattern capture bound to this parameter.
- **type** (str | *CppRef* | None) – Argument type for the synthesized call's prototype; flows into Typehoon as a per-argument subtype constraint.
- **type_hint** – Optional cpp::std unique name emitted as a direct vvar type hint (for by-value captures where the vvar *is* the object rather than a pointer to it).

**capture:** str

**type:** str | *CppRef* | None = None

**type_hint:** str | None = None

**__init__**(*capture*, *type=None*, *type_hint=None*)

**Parameters**

- **capture** (*str*)
- **type** (*str* | CppRef | *None*)
- **type_hint** (*str* | *None*)

**Return type**
None

**class** angr.analyses.decompiler.known_patterns.pattern.**KnownPattern**

Bases: object

A known code idiom, described declaratively.

**Variables**

- **name** (str) – Identifier, e.g. "std_string_length".
- **display_name** (str) – Human-readable name, e.g. "std::string::length".
- **call_name** (str) – Target name of the synthesized Call.
- **pattern** (*PatternExpr* | *PatternStmt* | *PGraphPat*) – The structural pattern to match.
- **params** (tuple[*PatternParam*, ...]) – Ordered parameters; their captures become the call arguments, in order.
- **returnty** (str | *CppRef* | None) – Return type of the synthesized call.

- **returnty_factory** (Callable[[Arch, dict[str, int]], *SimType* | None] | None) – Optional callable building a call-site-specific return type from the values of the constant `extra_args` captures (e.g. CONTAINING_RECORD returns a pointer to a record whose layout depends on the matched field offset). Falls back to `returnty` when it returns None or when the constant values are unavailable.
- **extra_args** (tuple[str, ...]) – Names of (typically constant) captures appended to the call arguments after `params`.
- **arches** (tuple[str, ...] | None) – Allowed `archinfo.Arch.name` values; None = any.
- **platforms** (tuple[str, ...] | None) – Allowed OS names (`project.simos.name`, lowercased); None = any.
- **where** (Callable[[dict[str, *Expression*]], bool] | None) – Optional cross-capture predicate evaluated on the bindings after a structural match.
- **collapse_capture** (str | None) – Optional capture name identifying the idiom that a match belongs to: within one function, matches binding it to the same virtual variable all describe *one* source-level idiom, and only the one with the largest `collapse_max_capture` constant is kept. The compiler folds CONTAINING_RECORD's subtraction into every field displacement, so one source idiom otherwise emits a call per field, each naming a different (and mostly wrong) record base.
- **collapse_max_capture** (str | None) – Capture whose constant value orders the collapsing; required when `collapse_capture` is set.
- **binary_guard** (Callable[[*Project*], bool] | None) – Optional predicate on the Project; the pattern is only used when it returns True (e.g. require C++ evidence for STL patterns to avoid false positives on plain C binaries).
- **default_enabled** (bool) – Whether the pattern is used when the caller does not explicitly select patterns. Generic patterns prone to false positives should set this False.

**name:** str

**display_name:** str

**call_name:** str

**pattern:** *PatternExpr* | *PatternStmt* | *PGraphPat*

**params:** tuple[*PatternParam*, ...]

**returnty:** str | *CppRef* | None = None

**returnty_factory:** Callable[[Arch, dict[str, int]], *SimType* | None] | None = None

**extra_args:** tuple[str, ...] = ()

**arches:** tuple[str, ...] | None = None

**platforms:** tuple[str, ...] | None = None

**where:** Callable[[dict[str, *Expression*]], bool] | None = None

**collapse_capture:** str | None = None

**collapse_max_capture:** str | None = None

**binary_guard:** Callable[[*Project*], bool] | None = None

**default_enabled:** bool = True

**suppressed_by:** tuple[str, str, str] | None = None

Drop a match of this pattern when a pattern whose name matches the regex matched on the same object: `(name regex, my capture, their capture)`. The two captures must bind `.likes()`-equal expressions. This is how a generic accessor yields to a specific one on the same base: a bare `Load(s + 8)` is std::string::length on a string and _M_finish on a vector, and the vector's other fields say which. Judged against every match of the suppressing family, selected or not, so it cannot interact with largest-match selection.

**claims_only:** bool = False

Match only to claim a base for `suppressed_by` purposes; never outlined, never rewritten, never reported. For shapes that identify an object beyond doubt but are not worth naming: a vector's capacity check says "this is a vector" and nothing a reader wants a call for.

**pure_calls:** frozenset[str] = frozenset({})

Callees this pattern reads through *PCallResult* whose only effect is their result: once the pattern has consumed that result and nothing else does, the call goes too. Naming a callee in a pattern is already a claim about what it computes; this is the claim that it computes nothing else. `__ctype_b_loc` returns a table pointer, and a bare `__ctype_b_loc();` left behind after `isspace(c)` is noise.

**applicable**(*arch_name*, *platform*)

**Return type**
bool

**Parameters**

- **arch_name** (*str*)
- **platform** (*str | None*)

**const_args_of_call**(*call*)

Recover the `extra_args` constant values from a synthesized call's trailing arguments. Returns None when the call does not carry them.

**Return type**
dict[str, int] | None

**Parameters**
**call** (Call)

**prototype**(*arch*, *const_args=None*)

Build the synthesized call's prototype. `const_args` (the values of the constant `extra_args` captures, see *const_args_of_call()*) enables call-site-specific return types via `returnty_factory`. Returns None if any declared type fails to resolve.

**Return type**
*SimTypeFunction* | None

**Parameters**

- **arch** (*archinfo.Arch*)
- **const_args** (*dict[str, int] | None*)

**__init__**(*name*, *display_name*, *call_name*, *pattern*, *params*, *returnty=None*, *returnty_factory=None*, *extra_args=()*, *arches=None*, *platforms=None*, *where=None*, *collapse_capture=None*, *collapse_max_capture=None*, *binary_guard=None*, *default_enabled=True*, *suppressed_by=None*, *claims_only=False*, *pure_calls=frozenset({})*)

**Parameters**

- **name** (*str*)
- **display_name** (*str*)
- **call_name** (*str*)
- **pattern** (PatternExpr | PatternStmt | PGraphPat)
- **params** (*tuple[PatternParam, ...]*)
- **returnty** (TypeRef | *None*)
- **returnty_factory** (Callable[[archinfo.Arch, dict[str, int]], SimType | None] | *None*)
- **extra_args** (*tuple[str, ...]*)
- **arches** (*tuple[str, ...]* | *None*)
- **platforms** (*tuple[str, ...]* | *None*)
- **where** (Callable[[dict[str, Expression]], *bool*] | *None*)
- **collapse_capture** (*str* | *None*)
- **collapse_max_capture** (*str* | *None*)
- **binary_guard** (Callable[[Project], *bool*] | *None*)
- **default_enabled** (*bool*)
- **suppressed_by** (*tuple[str, str, str]* | *None*)
- **claims_only** (*bool*)
- **pure_calls** (*frozenset[str]*)

**Return type**
None

### angr.analyses.decompiler.known_patterns.posix_macros

Single-expression glibc/POSIX macros that the preprocessor inlines into every caller, so they survive into decompiled output as bare bit arithmetic.

<sys/stat.h> file-type predicates all expand through one helper:

```
#define __S_ISTYPE(mode, mask)  (((mode) & __S_IFMT) == (mask))
```

with `__S_IFMT == 0170000` and one of the seven `__S_IFxxx` values, so each predicate is a two-node expression `(mode & 0xf000) == <S_IFxxx>`. The mask is the same in every libc and in the Windows CRT (`_S_IFMT`), and the pairing of that mask with exactly one of the seven legal type values is self-guarding, so these are enabled by default.

<sys/wait.h> status decoders (glibc `bits/waitstatus.h`):

```
#define __WTERMSIG(status)     ((status) & 0x7f)
#define __WIFEXITED(status)    (__WTERMSIG(status) == 0)
#define __WIFSIGNALED(status)  (((signed char) (((status) & 0x7f) + 1) >> 1) > 0)
#define __WIFSTOPPED(status)   (((status) & 0xff) == 0x7f)
#define __WEXITSTATUS(status)  (((status) & 0xff00) >> 8)
```

Only the first three leave enough residue to identify. gcc rewrites `WIFSIGNALED` into `(signed char)((status & 0x7f) + 1) > 1` (the `>> 1` and the `> 0` fold together), which is what is matched here; the signed compare is required, since the `(signed char)` cast is the whole point of the idiom. `WIFSTOPPED` narrows to a bare `(char)status == 0x7f` (the `& 0xff` is absorbed by the byte-sized compare) and `WTERMSIG` is a bare `status & 0x7f`; both are common enough shapes to be opt-in. `WEXITSTATUS` / `WSTOPSIG` (identical macros in glibc) are not matchable at all on x86: gcc compiles `(status & 0xff00) >> 8` to a single `movzbl %ah` and the decompiler renders it as a plain byte-sized virtual variable, leaving no shift or mask to match.

`WIFSIGNALED` does not match on x86-32, and should not be made to. There the `(signed char)` cast lifts to an `Extract` rather than a `Convert`, and gcc takes the *inverted* branch, so the AIL reads

> Extract(((status & 0x7f) + 1), 8bits@0) CmpLE 1<8>

The missing `Extract` node in the DSL is the smaller half of the problem: that expression is `!WIFSIGNALED(status)`, and a KnownPattern replaces the matched expression by the value of its synthesized call, so there is no way to spell the negation. A pattern matching this shape and emitting `WIFSIGNALED(status)` would silently swap the two arms of every wait-status branch on 32-bit: the "child was killed by signal N" arm would become the "exited normally" one. The x86-32 sites (0 of 13 busybox functions) are therefore a deliberate gap until the pattern model can express a negated result.

<sys/sysmacros.h> `major()` is an `extern __inline` function that -O2 inlines; its glibc encoding scatters the major number over bits 8-19 and 32-63:

```
__major  = ((__dev & 0x00000000000fff00u) >>  8);
__major |= ((__dev & 0xfffff00000000000u) >> 32);
```

which gcc reassociates into `((dev >> 8) & 0xfff) | ((dev >> 32) & 0xfffff000)` on 64-bit targets, and into a funnel-shift pair on 32-bit ones (see `_build_major32`). That constant quartet is unique enough to enable by default. `minor()` and `makedev()` compile to `Insert`/`Extract` AIL expressions for which the pattern DSL has no node, so they are not defined here.

Every macro argument is matched as a virtual variable (optionally behind a compiler-inserted narrowing Convert), never as a Load. The consequence is that a caller reading the mode straight out of a `struct stat` field at the point of use does not match at all: `PVVar.match` returns None on a Load, so the finder never produces a match. (It does *not* reach `_rewrite_callsite` and fail there; that error can only occur for patterns whose parameter capture is not a bare PVVar.) Measured on real -O2 code this costs less than it sounds: struct stat is almost always a stack local, so `st.st_mode` is lifted to a stack vvar that matches; only pointer dereferences such as `inode->i_mode` stay Loads.

Calibrated against tests/x86_64/decompiler/known_patterns_glibc_macros (gcc 12.2 -O2; re-checked at -O1/-O3, and against glibc 2.36 headers).

`angr.analyses.decompiler.known_patterns.posix_macros.`**`macro_operand`**`(`*`cap`*`)`

> A macro's scalar argument: a virtual variable, possibly narrowed by the compiler, or a field read.
>
> PVVar does not see through Convert wrappers on its own, and binding the pre-narrowing vvar keeps the synthesized call argument correctly typed.
>
> The `PLoad` arm is what makes `S_ISDIR(inode->i_mode)` matchable at all. Before the outliner could lift a parameter expression into a temporary, a capture had to be a virtual variable, so the same macro was recognized when its argument was a stack local and invisible when it was a field of a struct reached through a pointer, a split with no meaning to a reader. The mask and the type constant still carry the identification; the argument's shape never did.
>
> **Return type**
> *PChoice*
>
> **Parameters**
> **cap** (*str*)

### angr.analyses.decompiler.known_patterns.protobuf_hasbits

protobuf has-bits accessors (protoc output for optional fields):

```
has_field()   -> _has_bits_[w] & mask          (Load(m) And mask)
set_has()     -> _has_bits_[w] |= mask          (Store(m, Load(m) Or mask))
clear_has()   -> _has_bits_[w] &= ~mask         (Store(m, Load(m) And ~mask))
```

The `_has_bits_` word is a 32-bit int regardless of architecture, so the load width is fixed at 4. Generic bitfield ops, so opt-in; the mask is captured as an extra call argument. Calibrated against tests/x86_64/decompiler/known_patterns_protobuf (g++ -O2).

### angr.analyses.decompiler.known_patterns.registry

The template registry: every `KnownPatternTemplate` the package defines, keyed by call name and by human name, plus the helpers that turn a user's selection or a target's gates into the list of templates to match with.

Kept apart from the package `__init__` so that the finder and the call-info helpers can import it at module load without a cycle.

angr.analyses.decompiler.known_patterns.registry.**ALL_PATTERNS = 'all'**

Value of the `known_patterns` decompilation option that force-enables every registered template, opt-in ones included.

**exception** angr.analyses.decompiler.known_patterns.registry.**UnknownPatternError**

Bases: `ValueError`

Raised when a pattern selection names a template that is not registered.

angr.analyses.decompiler.known_patterns.registry.**register_pattern_template**(*template*)

Register a KnownPatternTemplate. Call names are unique across templates (the architecture / runtime conditionals live inside each template's `build`).

**Return type**
`None`

**Parameters**
**template** (`KnownPatternTemplate`)

angr.analyses.decompiler.known_patterns.registry.**patterns_for**(*ctx*, *templates=None*, ***, *enabled_only=False*)

Instantiate the applicable templates for `ctx` into concrete KnownPatterns. `templates` defaults to the whole registry; with `enabled_only` only default-enabled templates are used.

**Return type**
`list`[*KnownPattern*]

**Parameters**

- **ctx** (`PatternContext`)
- **templates** (*Iterable[KnownPatternTemplate] | None*)
- **enabled_only** (*bool*)

angr.analyses.decompiler.known_patterns.registry.**resolve_pattern_selection**(*selection*)

Resolve a user's force-enable selection into templates.

`selection` is one of:

- `None` / empty: nothing is force-enabled (returns an empty list);

- "all": every registered template, opt-in ones included;
- an iterable of template name and/or call_name values (a comma-separated string is accepted too, for the string-valued decompilation option).

An unrecognized name raises *UnknownPatternError* rather than silently selecting nothing.

**Return type**
list[*KnownPatternTemplate*]

**Parameters**
**selection** (*str | Iterable[str] | None*)

angr.analyses.decompiler.known_patterns.registry.**partition_templates**(*gate_ctx*, *forced=()*, *templates=None*)

Split templates into (enabled, deferred) for one target.

enabled are the templates to match with right away: default-on ones, ones the caller force-enabled, and ones whose gate already opens on target evidence alone. deferred are the ones whose gate needs per-function evidence (see *CorroboratedBy*) and must be re-evaluated by the finder once the first matching stage has run.

**Return type**
tuple[list[*KnownPatternTemplate*], list[*KnownPatternTemplate*]]

**Parameters**

- **gate_ctx** (GateContext)
- **forced** (*Iterable[KnownPatternTemplate]*)
- **templates** (*Iterable[KnownPatternTemplate] | None*)

### angr.analyses.decompiler.known_patterns.serialize

JSON round-trip for the plain-data subset of the pattern DSL.

Patterns are frozen dataclasses of ints, strings, sets and other patterns, which serialize naturally, plus a few callables (PConst.pred, KnownPattern.where, binary_guard, returnty_factory) which do not. The built-in pattern library uses those callables; a pattern authored in a UI never does. The codec covers the former's data and refuses the latter by name, so a pattern that cannot round-trip says so instead of coming back subtly different.

**exception** angr.analyses.decompiler.known_patterns.serialize.**NotSerializableError**

Bases: ValueError

The pattern holds a value (a callable) that has no JSON form.

angr.analyses.decompiler.known_patterns.serialize.**node_to_dict**(*node*)

A JSON-ready dict for one pattern node and everything under it.

**Return type**
dict[str, Any]

**Parameters**
**node** (PatternNode)

angr.analyses.decompiler.known_patterns.serialize.**node_from_dict**(*data*)

The inverse of *node_to_dict()*.

**Return type**
*PatternNode*

**Parameters**
**data** (*dict[str, Any]*)

angr.analyses.decompiler.known_patterns.serialize.**known_pattern_to_dict**(*pattern*)

A JSON-ready dict for a whole KnownPattern. Refuses callables by name.

**Return type**
dict[str, Any]

**Parameters**
**pattern** (KnownPattern)

angr.analyses.decompiler.known_patterns.serialize.**known_pattern_from_dict**(*data*)

The inverse of *known_pattern_to_dict()*.

**Return type**
*KnownPattern*

**Parameters**
**data** (*dict[str, Any]*)

angr.analyses.decompiler.known_patterns.serialize.**dumps**(*pattern*, ***json_kwargs*)

**Return type**
str

**Parameters**
**pattern** (KnownPattern | PatternNode)

angr.analyses.decompiler.known_patterns.serialize.**loads**(*text*)

**Return type**
*KnownPattern* | *PatternNode*

**Parameters**
**text** (*str*)

### angr.analyses.decompiler.known_patterns.std_string_cstr

Inlined MSVC `std::string::c_str()` / `data()`: the small-string optimization (SSO) select.

The MSVC STL stores the character buffer in a 16-byte union `_Bx` at offset 0 (either an inline `_Buf[16]` or, for long strings, a heap `_Ptr`), the size at offset 16, and the capacity `_Myres` one word further on. `c_str()` returns the inline buffer address when the string is short and the heap pointer when it is long, i.e.:

```
result = &s->_Bx;                 // == s   (the buffer address)
if (s->_Myres >= 16)              // capacity past the SSO threshold?
    result = s->_Bx._Ptr;        // == *(void**)s  (the heap pointer)
```

which the compiler lowers to a control-flow diamond. In clean SSA it is:

```
entry:  if (Load(s + cap_off) < 16) goto merge else goto heap
heap:   h = Load(s)
merge:  result = Phi(h [heap], s [entry])          // Phi(*s, s)
```

so it is a `PGraphPat` (entry + heap; the phi merge is the frontier) rather than an expression idiom. This matches the SSA form before de-phi, the form the KnownPatternOutliner pass sees when it runs at BEFORE_VARIABLE_RECOVERY, so the idiom is recognized and outlined during decompilation. (SSA destruction later inserts `res = s` / `h2 = h` copies that would obscure this shape; matching the clean form avoids depending on them and needs no cross-copy unification.) The offsets are word-scaled (cap_off is 24 on x64, 20 on x86); the 16-byte SSO threshold is fixed for `char` strings.

libstdc++ `c_str()` is a bare `_M_p` load (no SSO branch) and is not matched here. Opt-in, because a control-flow select is fairly generic. Calibrated against tests/x86_64/windows/known_patterns_msvc_string_cstr.exe (MSVC 19 /O2).

### angr.analyses.decompiler.known_patterns.std_string_dtor

The inlined `std::string` destructor.

`~basic_string()` is one line of source and, at -O2, five lines of machine code that the compiler emits at every scope exit of every local string and in every destructor of every class holding one. It is by a wide margin the most common inlined idiom in C++ binaries: the DWARF inline records of the -O2 benchmark corpus put `~basic_string` / `_M_dispose` / `_M_destroy` at 5.9M sites across 245 binaries, an order of magnitude above any accessor.

libstdc++ frees the buffer only when the string is not using its small-string buffer, which is exactly the SSO test `capacity()` also uses:

```
if (_M_p != &_M_local_buf)
    operator delete(_M_p, _M_allocated_capacity + 1);
```

a triangle whose taken arm is a single call. Four things have to agree for a match: the same object address in the compare and in both loads, the local buffer's offset appearing both as an address and as a field, the `+ 1`, and the callee being `operator delete`. That is what makes this pattern self-guarding enough to be on by default. The `+ 1` is the NUL terminator: libstdc++ allocated `capacity + 1` bytes and hands the same number back to the sized `operator delete`.

Sized deallocation is a C++14 feature and a compiler switch, so the one-argument `operator delete(void *)` spelling gets its own template; the two cannot share one pattern object because a statement pattern has no PChoice.

Calibrated against tests/x86_64/decompiler/known_patterns_stl5 (g++ 12.2.0 -O2).

**angr.analyses.decompiler.known_patterns.std_string_dtor.OPERATOR_DELETE = frozenset({'??3@YAXPAX@Z', '??3@YAXPAXI@Z', '??3@YAXPEAX@Z', '??3@YAXPEAX_K@Z', '_ZdlPv', '_ZdlPvSt11align_val_t', '_ZdlPvj', '_ZdlPvjSt11align_val_t', '_ZdlPvm', '_ZdlPvmSt11align_val_t', 'operator delete(void*)', 'operator delete(void*, unsigned int)', 'operator delete(void*, unsigned long)'})**

> Every spelling of `operator delete` a compiler emits for this idiom. The mangled names are exact; the demangled ones are accepted too because *PCall* matches against both and a stripped-but-imported callee may only be known by one of them.

### angr.analyses.decompiler.known_patterns.std_string_internals

libstdc++ std::string internals that are not accessors: the SSO test and the two length-setting idioms.

`_M_set_length(n)` is what every mutating operation ends with. It stores the new length and re-terminates the buffer:

```
s->_M_string_length = n;
s->_M_p[n] = '\0';
```

768K DWARF inline sites across 242 binaries of the -O2 benchmark corpus, third after the destructor and the SSO test. It is self-guarding because `n` appears twice: once as the stored length and once as the offset added to the data pointer, against a base the two field displacements already pin down.

`clear()` is the same idiom with `n == 0`, and is a different pattern: with no offset to add there is no second occurrence of `n` to unify on, so the shape degrades to "zero a word at +8 and a byte through the pointer at +0". That is a plausible reset of any pointer-and-count pair, so it is opt-in and corroborated.

`_M_is_local()` is the SSO test on its own, `_M_p == &_M_local_buf`, the same comparison the destructor guards on and `capacity()` selects on. It is opt-in for a different reason: wherever it appears as part of one of those, the larger match wins and this one is redundant; what is left over is the handful of places where the test stands alone.

Calibrated against tests/x86_64/decompiler/known_patterns_stl5 (g++ 12.2.0 -O2).

### angr.analyses.decompiler.known_patterns.std_string_length

Inlined std::string::length() / size() and empty().

The length field is an 8- or 4-byte load of the string's size member. libstdc++ keeps `_M_string_length` one word past the data pointer; the MSVC STL keeps `_Mysize` behind a fixed 16-byte SSO buffer union (see *layouts*). One template covers all of {libstdc++, MSVC} x {32, 64}-bit.

Calibrated against tests/x86_64/decompiler/known_patterns_stl (g++ 12.2.0 -O2), tests/x86_64/windows/known_patterns_stl_msvc_17_x64.exe and tests/i386/windows/known_patterns_stl_msvc_17_x86.exe (VS 2022 /O2).

### angr.analyses.decompiler.known_patterns.std_swap

Inlined `std::swap`, the three-move exchange of two memory locations.

Three statement orders occur, and all three are common:

- as written, with the second value read inline:

```
t = *a;  *a = *b;  *b = t;
```

- as scheduled, with both loads hoisted, which is what any instruction scheduler produces, and what gcc emits for a struct assignment that swaps field by field:

```
t1 = *a;  t2 = *b;  *a = t2;  *b = t1;
```

- the same, storing in the other order:

```
t1 = *a;  t2 = *b;  *b = t1;  *a = t2;
```

  which differs from the previous one with `a` and `b` renamed: that renaming also swaps the two loads, so the sequence differs either way round. gcc emits it for consecutive field swaps, where it lets the store to one field sit next to the load of the next.

They cannot share a pattern object, since a statement sequence is one object, so each is its own template. The width is a parameter; see `_SWAP_WIDTHS`.

The addresses are *PField* captures rather than bare variables because swapping fields is the usual case (`std::swap(lhs.n, rhs.n)` inside a move assignment): the address arrives as `obj + 8`, and the outliner materializes the pointer for the call.

Calibrated against tests/x86_64/decompiler/known_patterns_multiblock (g++ -O2).

angr.analyses.decompiler.known_patterns.std_swap.**STD_SWAP = KnownPatternTemplate(call_name='std::swap (1b)', build=<function _make_swap_template.<locals>.build>, arches=frozenset({'AMD64', 'X86'}), languages=frozenset({'cpp'}), runtimes=None, platforms=None, default_enabled=False, name='std_swap_1', gate=None)**

the word-sized, as-written spelling, the one the fixture tests

### angr.analyses.decompiler.known_patterns.std_vector_size

Inlined std::vector<T>::size() and capacity().

libstdc++ and the MSVC STL both lay out std::vector as three pointers (_M_start/_M_finish/_M_end_of_storage), so both accessors are one pointer difference divided by sizeof(T):

size() == (_M_finish - _M_start) / sizeof(T) capacity() == (_M_end_of_storage - _M_start) / sizeof(T)

i.e. the same shape reading a different minuend field. The field offsets and load width come from the `PatternContext` (word-scaled), so one definition covers 32- and 64-bit.

`sizeof(T)` is not recoverable from anything but the divisor, so there is one template per element size. Three ranges of sizeof(T) need three spellings:

- a power of two up to 8: a bare shift, and there is a named C++ type of that width (short/int/long long);
- a power of two above 8: still a bare shift, but no named type, so the element is the opaque `T<N>` class (`sizeof(std::string) == 32`, and `std::vector<std::string>` is the corpus' most common element type);
- not a power of two: the exact-division magic-multiply idiom below.

`sizeof(T) == 1` is not covered for size()/capacity(): with no shift the idiom is a bare pointer difference, too generic to name.

Calibrated against the known_patterns_stl binaries (libstdc++ ELF, MSVC x64/x86).

angr.analyses.decompiler.known_patterns.std_vector_size.**exact_div_magic**(*elt_size*, *bits*)

`(shift, magic)` of the exact-division-by-`elt_size` idiom.

**Return type**
`tuple`[`int`, `int`]

**Parameters**

- **elt_size** (*int*)
- **bits** (*int*)

angr.analyses.decompiler.known_patterns.std_vector_size.**make_std_vector_size_template**(*elt_name*, *log2_elt_size*)

A power-of-two `std::vector<elt_name>::size` template.

**Parameters**

- **elt_name** (*str*)
- **log2_elt_size** (*int*)

angr.analyses.decompiler.known_patterns.std_vector_size.**make_std_vector_size_exactdiv_template**(*elt_name*, *elt_size*)

A non-power-of-two `std::vector<elt_name>::size` template.

**Parameters**

- **elt_name** (*str*)
- **elt_size** (*int*)

angr.analyses.decompiler.known_patterns.std_vector_size.**STD_VECTOR_EXACTDIV_SIZES = (3, 5, 6, 7, 9, 10, 11, 12, 13, 14, 15, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511)**

Every opaque element size, power-of-two and not. The list is wide on purpose: sizeof(T) is whatever the program's record happens to be (112 for CryptoPP::ECPPoint, say), and a size that is not covered leaves the raw magic multiply in the output, which is the shape this pattern exists to remove.

angr.analyses.decompiler.known_patterns.std_vector_size.**STD_VECTOR_STACK_TEMPLATES = [KnownPatternTemplate(call_name='std::vector<short>::size (stack)', build=<function _make_vector_div_template.<locals>.build>, arches=frozenset({'AMD64', 'X86'}), languages=frozenset({'cpp'}), runtimes=None, platforms=None, default_enabled=True, name='std_vector_short_size_stack', gate=None), KnownPatternTemplate(call_name='std::vector<int>::size (stack)', build=<function _make_vector_div_template.<locals>.build>, arches=frozenset({'AMD64', 'X86'}), languages=frozenset({'cpp'}), runtimes=None, platforms=None, default_enabled=True, name='std_vector_int_size_stack', gate=None), KnownPatternTemplate(call_name='std::vector<long long>::size (stack)', build=<function _make_vector_div_template.<locals>.build>, arches=frozenset({'AMD64', 'X86'}), languages=frozenset({'cpp'}), runtimes=None, platforms=None, default_enabled=True, name='std_vector_long_long_size_stack', gate=None)]**

same shape, slots instead of loads. Only the named element sizes; the opaque T<N> set would double a four-figure library for a shape that is only reachable where the object never escapes to a pointer.

**Type**
Stack twins of *size*()

### angr.analyses.decompiler.known_patterns.stl_accessors2

C++ STL accessors, round two: std::string capacity/back/front and std::vector<T>::back().

`std::string::capacity()` is the only control-flow idiom here. libstdc++ lays std::string out as `{ _M_p , _M_string_length , union { _M_local_buf[16] | _M_allocated_capacity } }`, so `capacity()` is the SSO select:

```
_M_p == &_M_local_buf ? 15 : _M_allocated_capacity
```

i.e. a diamond. Unlike the MSVC `c_str()` triangle (see *std_string_cstr*), both arms of this diamond assign a value, so ITERegionConverter, which runs at AFTER_GLOBAL_SIMPLIFICATION, before the KnownPatternOutliner at BEFORE_VARIABLE_RECOVERY, has already folded the region into a single `x = c ? a : b` assignment by the time patterns are matched. The idiom is therefore a *PITE* expression pattern, not a PGraphPat. (When gcc's tail duplication copies the join into both arms instead of merging them, no ITE and no single-exit region exists and the idiom is not matched; that is intended, since there is nothing to outline.)

The comparison `Load(s) == s + 16`, a loaded pointer tested against the object's own address plus the union offset, is what makes the pattern self-guarding; the SSO threshold 15 is fixed for `char` strings, and the union offset is word-scaled, so one definition covers 32- and 64-bit.

`back()`/`front()` are plain expression idioms: `*(_M_p + size - 1)` and `*_M_p`. `std::vector<T>::back()` is `*(_M_finish - sizeof(T))`.

Calibrated against tests/x86_64/decompiler/known_patterns_stl2 (g++ 12.2.0 -O2).

angr.analyses.decompiler.known_patterns.stl_accessors2.**make_std_vector_back_template**(*elt_name*, *elt_size*, *returnty*)

A `std::vector<elt_name>::back` template: `*(_M_finish - sizeof(T))`.

**Parameters**

- **elt_name** (*str*)
- **elt_size** (*int*)
- **returnty** (*str*)

### angr.analyses.decompiler.known_patterns.stl_containers

C++ STL std::vector accessors beyond size()/capacity(): empty / operator[].

The three-pointer vector layout is shared by libstdc++ and the MSVC STL, so a single template per accessor, with word-scaled offsets and pointer-sized loads from the `PatternContext`, covers 32- and 64-bit on either runtime.

`capacity()` lives in *std_vector_size* with `size()`: the two are one expression against different fields, and both need a template per element size.

Calibrated against the known_patterns_stl binaries (libstdc++ ELF, MSVC x64/x86).

angr.analyses.decompiler.known_patterns.stl_containers.**make_std_vector_index_template**(*elt_name*, *elt_size*, *returnty*)

A `std::vector<elt_name>::operator[]` template: `*(_M_start + i * sizeof(T))`.

One per element size. Only the 4-byte (int) template existed, which covers 5% of the corpus' DWARF sites for this accessor: 78% of them are 8-byte elements (`unsigned long long` alone is 30%, pointers another 14%).

The scale is matched as `Mul` *or* `Shl`: a power-of-two element size lifts from *lea (%rax,%rdx,8)* either way depending on how the index reached the address, and pinning one spelling silently halves the coverage.

**Parameters**

- **elt_name** (*str*)
- **elt_size** (*int*)
- **returnty** (*str*)

### angr.analyses.decompiler.known_patterns.symbols

Symbol names as the portable spelling of an address.

A pattern lifted from one binary pins the addresses it saw; the same global lives elsewhere in every other build. Naming the symbol instead lets the pattern match wherever the loader can find that name.

angr.analyses.decompiler.known_patterns.symbols.**symbol_name_at**(*loader*, *addr*)

The unversioned name of the symbol at `addr`, or None.

**Return type**
`str` | `None`

**Parameters**

- **loader** (*Loader*)
- **addr** (*int*)

angr.analyses.decompiler.known_patterns.symbols.**symbol_addr**(*loader*, *name*)

Where `name` lives in this binary, or None if it has no such symbol.

**Return type**
`int` | `None`

**Parameters**

- **loader** (*Loader*)
- **name** (*str*)

### angr.analyses.decompiler.known_patterns.templates

KnownPatternTemplate: a single, context-parameterized definition of an idiom that instantiates itself into a concrete `KnownPattern` for a target's `PatternContext`.

One template replaces the per-architecture / per-runtime copies of a pattern: its `build(ctx)` computes the concrete field offsets, load sizes, and return types from the context, so the same definition covers 32- and 64-bit, libstdc++ and MSVC, and so on.

**class** angr.analyses.decompiler.known_patterns.templates.**KnownPatternTemplate**

Bases: `object`

A context-aware pattern definition.

**Variables**

- **call_name** (`str`) – The synthesized call name (unique across templates).
- **build** (`Callable[[PatternContext], KnownPattern | None]`) – `build(ctx) -> KnownPattern | None`; emits the concrete pattern for `ctx` (None if it cannot).
- **arches** (`frozenset[str] | None`) – Allowed `Arch.name` values; None = any.

- **languages** (frozenset[str] | None) – Allowed languages ({"c","cpp"}); None = any.
- **runtimes** (frozenset[str] | None) – Allowed C++ runtimes ({"libstdcxx","msvc"}); None = any.
- **platforms** (frozenset[str] | None) – Allowed platforms ({"linux","windows"}); None = any.
- **default_enabled** (bool) – Whether the template is used when the caller does not explicitly select patterns.
- **gate** – Optional *PatternGate* that turns an opt-in template on for targets (or functions) where the evidence says the idiom is real; see *gating*. A gate can only open a template, never close a default-on one.

**call_name:** str

**build:** Callable[[*PatternContext*], *KnownPattern* | None]

**arches:** frozenset[str] | None = None

**languages:** frozenset[str] | None = None

**runtimes:** frozenset[str] | None = None

**platforms:** frozenset[str] | None = None

**default_enabled:** bool = False

**name:** str = ''

**gate:** *PatternGate* | None = None

**enabled_for**(*gate_ctx*)

**Return type**
bool

**Parameters**
**gate_ctx** (GateContext)

**applicable**(*ctx*)

**Return type**
bool

**Parameters**
**ctx** (PatternContext)

**instantiate**(*ctx*)

The concrete pattern for ctx, or None if this template does not apply there. Memoized: a KnownPattern is a frozen tree that depends on nothing but the context, and callers treat it read-only.

**Return type**
*KnownPattern* | None

**Parameters**
**ctx** (PatternContext)

__init__(*call_name*, *build*, *arches=None*, *languages=None*, *runtimes=None*, *platforms=None*, *default_enabled=False*, *name=''*, *gate=None*, *_cache=<factory>*)

**Parameters**

- **call_name** (*str*)
- **build** (*Callable[[PatternContext], KnownPattern | None]*)
- **arches** (*frozenset[str] | None*)
- **languages** (*frozenset[str] | None*)
- **runtimes** (*frozenset[str] | None*)

- **gate** (*PatternGate | None*)

### angr.analyses.decompiler.known_patterns.vector_claims

Claims-only std::vector fingerprints: shapes that identify a vector beyond doubt but are not worth a call of their own.

They exist for one reason. `std::string::length` is a bare word load at +8, and so is `std::vector::_M_finish`: 63% of `length`'s false positives on the benchmark corpus sit in functions with a vector at that very site. The generated `size()`/`capacity()` templates already claim a base wherever they match, but they need a shift or a magic multiply

to key on; two common vector shapes carry neither, and are matched here purely so the base counts as a vector's (see *claims_only*):

- `Load(v + 8) - Load(v)`: `size()` of a one-byte element type, which no size() template covers because there is nothing to divide by;
- `Load(v + 8) ==/!= Load(v + 16)`: `push_back`'s capacity check, `_M_finish == _M_end_of_storage`, the shape behind the review's own example of a vector named as a string.

A string never subtracts its length from its data pointer, and compares its length with its capacity only in `size() == capacity()`, which is rare enough inline to accept.

### angr.analyses.decompiler.known_patterns.vector_math

3-component float vector math (glm / DirectXMath / game-graphics code).

Scalar float arithmetic compiles to SSE mulss/addss, which the lifter lowers from their 128-bit vector form to 32-bit floating-point Mul/Add over Load(..., 4) operands. The ops must be floating point: the same shape over integer Mul/Add is an integer dot product. Intel-SSE specific (float width is 4 bytes regardless of pointer size), so these are not word-scaled. Opt-in; calibrated against tests/x86_64/decompiler/known_patterns_vecmath (g++ -O2 -fno-tree-vectorize).

### angr.analyses.decompiler.known_patterns.wdk_shared_data

Reads of `KUSER_SHARED_DATA`, the page Windows maps read-only at the fixed virtual address `0x7FFE0000` in every user-mode process (x86, x64 and ARM64 alike). ntdll, kernel32 and countless drivers read its fields through the `SharedUserData` macro of ntddk.h/wdm.h, which compiles to a bare load from an absolute constant address:

```
SharedUserData->NtMajorVersion   ==   *(volatile ULONG *)0x7FFE026C
```

Kernel-mode code reaches the same page through `KI_USER_SHARED_DATA` (`0xFFDF0000` on x86, `0xFFFFF78000000000` on x64), so each field's pattern accepts the user- and the arch-appropriate kernel-mode address.

The absolute address is the guard here: there is no plausible non-Windows meaning for a load from `0x7FFE0000 + small offset`, so these are default-on and take no parameters (`params={}`); the synthesized call is a nullary accessor whose return type is the field's type.

Field offsets are those of the WDK `ddk/ntddk.h` `KUSER_SHARED_DATA` (cross-checked with `offsetof` on i686 and x86_64, and against Geoff Chappell's version-annotated layout); only offsets that have been stable from Windows XP through Windows 11 are default-on. Calibrated against tests/x86_64/windows/known_patterns_wdk_ksud.exe (-O2, mingw).

**class** angr.analyses.decompiler.known_patterns.wdk_shared_data.**KsudField**

Bases: `object`

One KUSER_SHARED_DATA field access: its byte offset, the load width used to read it, and the accessor's name.

`stable` is False for offsets that moved between Windows versions; those templates exist but are not enabled by default.

**offset:** `int`

**name:** `str`

**size:** `int`

**stable:** `bool` = **True**

**__init__**(*offset*, *name*, *size*, *stable=True*)

**Parameters**

- **offset** (*int*)
- **name** (*str*)
- **size** (*int*)
- **stable** (*bool*)

**Return type**
None

angr.analyses.decompiler.known_patterns.wdk_shared_data.**make_shared_user_data_template**(*field*)

A `SharedUserData->` field-read template for one KUSER_SHARED_DATA field: a load of `field.size` bytes from the field's fixed address.

**Parameters**
**field** (KsudField)

angr.analyses.decompiler.known_patterns.wdk_shared_data.**make_ntstatus_severity_template**(*macro*, *severity*)

An NTSTATUS severity-predicate template: `(s >> 30) == severity`, in either the literal shift form or the mask form the compilers prefer.

**Parameters**

- **macro** (*str*)
- **severity** (*int*)

### angr.analyses.decompiler.label_collector

**class** angr.analyses.decompiler.label_collector.**LabelCollector**

Bases: object

Collect all labels.

**__init__**(*node*)

### angr.analyses.decompiler.mixins

**class** angr.analyses.decompiler.mixins.**CFAMixin**

Bases: object

Control Flow Analysis Mixin

**__init__**(*graph*, *project*)

**num_predecessors**(*block*)

**get_one_predecessor**(*block*)

**Return type**
Block

**num_successors**(*block*)

**get_one_successor**(*block*)

**Return type**
Block

**static first_non_label_stmt**(*block*)

**Return type**
*Statement* | None

**static last_stmt**(*block*)

**Return type**
*Statement* | None

**static replace_stmt**(*block*, *stmts*, *replacement*)

**terminal_call**(*block*)

**Return type**
*Call* | None

**get_call_target**(*call*)

**Return type**
str | None

**Parameters**
**call** (Call)

**match_call**(*block_or_stmt*, *expected*, *monopolize=True*, *use_trait_name=True*)

**class** angr.analyses.decompiler.mixins.**CFGTransformationMixin**

Bases: object

Mixin providing CFG graph transformation operations (block removal, splitting, etc.).

**__init__**(*graph*)

**update_block_indexes**()

**remove_jump_target**(*block*, *jump_target*, *jump_target_idx*)

**Parameters**

- **block** (*Block*)
- **jump_target** (Const | *int*)
- **jump_target_idx** (*int*)

**remove_false_branch**(*block*)

**Parameters**
**block** (*Block*)

**replace_jump_target**(*block*, *old_target*, *old_target_idx*, *new_target*, *new_target_idx*)

**Parameters**

- **old_target** (Const | *int* | *None*)
- **old_target_idx** (*int*)
- **new_target** (Const | *int*)

- **new_target_idx** (*int*)

**remove_block**(*block*)

**Parameters**
**block** (*Block*)

**split_block**(*block*, *new_head_stmt*)

**Parameters**
**block** (*Block*)

**class** angr.analyses.decompiler.mixins.**DFAMixin**

Bases: object

Data Flow Analysis Helper

**__init__**(*graph=None*)

**collect_stack_defs_at**(*block*)

Collect stack definitions at specific block

**collect_callsite_stack_defs**(*callsite_block*, *max_blocks=1*)

Collect stack variable definitions at a given callsite

**static extract_write_to_stack_vvar**(*stmt*)

**Return type**
tuple[*VirtualVariable* | None, *Expression* | None]

**static extract_stack_data_flow**(*stmt*)

**find_reg_ptr_to_reg_data_flow**(*block*, *reg_vvar*)

**find_stack_data_flow**(*block*, *src_offset*, *size*)

**static extract_stack_to_reg_data_flow**(*stmt*)

**find_stack_to_reg_data_flow**(*block*, *src_offset*, *size*)

**get_def_block_and_stmt**(*data*)

**class** angr.analyses.decompiler.mixins.**SRDAMixin**

Bases: object

Mixin providing SSA reaching definitions analysis access.

**__init__**(*subject*, *graph*, *project*, *variable_map*)

**Parameters**
**variable_map** (VariableMap)

**get_vvar_value**(*vvar*)

**Return type**
*Expression* | None

**Parameters**
**vvar** (VirtualVariable)

**get_terminal_vvar_values**(*vvar*, *visited=None*)

**get_terminal_vvar_value**(*vvar*, *visited=None*)

**get_terminal_vvar**(*vvar*, *visited=None*)

**get_stack_vvar_by_insn**(*stack_offset*, *addr*, *block_idx=0*, *size=None*, *op_type=ObservationPointType.OP_BEFORE*)

**Return type**
*VirtualVariable* | None

**Parameters**

- **stack_offset** (*int*)
- **addr** (*int*)
- **block_idx** (*int*)

**get_stack_vvars_by_insn**(*stack_offset*, *addr*, *block_idx=0*, *size=None*, *op_type=ObservationPointType.OP_BEFORE*)

All definitions of the stack slot that reach the instruction, one per varid.

**Return type**
list[*VirtualVariable*]

**Parameters**

- **stack_offset** (*int*)
- **addr** (*int*)
- **block_idx** (*int*)

**get_stack_vvar_and_offset_by_insn**(*stack_offset*, *addr*, *block_idx=0*, *op_type=ObservationPointType.OP_BEFORE*)

**Return type**
tuple[*VirtualVariable*, int] | tuple[None, None]

**Parameters**

- **stack_offset** (*int*)
- **addr** (*int*)
- **block_idx** (*int*)

**get_vvar_type**(*vvar*)

**Return type**
*SimType* | None

**get_def_by_vvar**(*vvar*)

**class** angr.analyses.decompiler.mixins.**SSAVariableMixin**

Bases: object

Mixin for creating and fixing SSA stack virtual variables.

**__init__**(*context*)

**Parameters**
**context** (OptimizationPass)

**new_stack_vvar**(*dst_offset*, *bits*, *tags*, *record=True*)

**ambiguous_new_stack_vvars**()

Varids of new stack vvars that reach a use of their slot together with a pre-existing definition, i.e., the slot's earlier value is still live where the new value arrives. No phi merges them.

**Return type**
set[int]

**fix_stack_vvar_uses**()

### Submodules

*cfa_mixin*
*cfg_transformation_mixin*
*dfa_mixin*
*srda_mixin*
*ssa_variable_mixin*

### angr.analyses.decompiler.mixins.cfa_mixin

**class** angr.analyses.decompiler.mixins.cfa_mixin.**CFAMixin**

Bases: object

Control Flow Analysis Mixin

**__init__**(*graph*, *project*)

**num_predecessors**(*block*)

**get_one_predecessor**(*block*)

**Return type**
Block

**num_successors**(*block*)

### angr.analyses.decompiler.mixins.cfg_transformation_mixin

**class** angr.analyses.decompiler.mixins.cfg_transformation_mixin.**CFGTransformationMixin**

Bases: object

Mixin providing CFG graph transformation operations (block removal, splitting, etc.).

**__init__**(*graph*)

**update_block_indexes**()

**remove_jump_target**(*block*, *jump_target*, *jump_target_idx*)

**Parameters**

- **block** (*Block*)
- **jump_target** (Const | *int*)
- **jump_target_idx** (*int*)

**remove_false_branch**(*block*)

**Parameters**
**block** (*Block*)

**replace_jump_target**(*block*, *old_target*, *old_target_idx*, *new_target*, *new_target_idx*)

**Parameters**

- **old_target** (Const | *int* | *None*)
- **old_target_idx** (*int*)
- **new_target** (Const | *int*)
- **new_target_idx** (*int*)

**remove_block**(*block*)

**Parameters**
**block** (*Block*)

**split_block**(*block*, *new_head_stmt*)

**Parameters**
**block** (*Block*)

### angr.analyses.decompiler.mixins.dfa_mixin

**class** angr.analyses.decompiler.mixins.dfa_mixin.**StackDefinition**

Bases: object

A definition of a stack variable.

**data:** *Expression*

**stmt:** *Statement*

**stmt_idx:** int

**block:** Block

**__init__**(*data*, *stmt*, *stmt_idx*, *block*)

**Parameters**

- **data** (Expression)
- **stmt** (Statement)
- **stmt_idx** (*int*)
- **block** (*Block*)

**Return type**
None

**class** angr.analyses.decompiler.mixins.dfa_mixin.**DFAMixin**

Bases: object

Data Flow Analysis Helper

**__init__**(*graph=None*)

**collect_stack_defs_at**(*block*)

Collect stack definitions at specific block

**collect_callsite_stack_defs**(*callsite_block*, *max_blocks=1*)

Collect stack variable definitions at a given callsite

**static extract_write_to_stack_vvar**(*stmt*)

**Return type**
tuple[*VirtualVariable* | None, *Expression* | None]

**static extract_stack_data_flow**(*stmt*)

**find_stack_data_flow**(*block*, *src_offset*, *size*)

**static extract_stack_to_reg_data_flow**(*stmt*)

**find_stack_to_reg_data_flow**(*block*, *src_offset*, *size*)

**get_def_block_and_stmt**(*data*)

### angr.analyses.decompiler.mixins.srda_mixin

**class** angr.analyses.decompiler.mixins.srda_mixin.**SRDAMixin**

Bases: object

Mixin providing SSA reaching definitions analysis access.

**__init__**(*subject*, *graph*, *project*, *variable_map*)

**Parameters**
**variable_map** (VariableMap)

**get_vvar_value**(*vvar*)

**Return type**
*Expression* | None

**Parameters**
**vvar** (VirtualVariable)

**get_terminal_vvar_values**(*vvar*, *visited=None*)

**get_terminal_vvar_value**(*vvar*, *visited=None*)

**get_terminal_vvar**(*vvar*, *visited=None*)

**get_stack_vvar_by_insn**(*stack_offset*, *addr*, *block_idx=0*, *size=None*, *op_type=ObservationPointType.OP_BEFORE*)

**Return type**
*VirtualVariable* | None

**Parameters**

- **stack_offset** (*int*)
- **addr** (*int*)
- **block_idx** (*int*)

**get_stack_vvars_by_insn**(*stack_offset*, *addr*, *block_idx=0*, *size=None*, *op_type=ObservationPointType.OP_BEFORE*)

All definitions of the stack slot that reach the instruction, one per varid.

**Return type**
list[*VirtualVariable*]

**Parameters**

- **stack_offset** (*int*)
- **addr** (*int*)
- **block_idx** (*int*)

**get_stack_vvar_and_offset_by_insn**(*stack_offset*, *addr*, *block_idx=0*, *op_type=ObservationPointType.OP_BEFORE*)

**Return type**
tuple[*VirtualVariable*, int] | tuple[None, None]

**Parameters**

- **stack_offset** (*int*)

- **addr** (*int*)
- **block_idx** (*int*)

**get_vvar_type**(*vvar*)

**Return type**
*SimType* | None

**get_def_by_vvar**(*vvar*)

### angr.analyses.decompiler.mixins.ssa_variable_mixin

**class** angr.analyses.decompiler.mixins.ssa_variable_mixin.**SSAVariableMixin**

Bases: object

Mixin for creating and fixing SSA stack virtual variables.

**__init__**(*context*)

**Parameters**
**context** (OptimizationPass)

**new_stack_vvar**(*dst_offset*, *bits*, *tags*, *record=True*)

**ambiguous_new_stack_vvars**()

Varids of new stack vvars that reach a use of their slot together with a pre-existing definition, i.e., the slot's earlier value is still live where the new value arrives. No phi merges them.

**Return type**
set[int]

**fix_stack_vvar_uses**()

### angr.analyses.decompiler.node_replacer

**class** angr.analyses.decompiler.node_replacer.**NodeReplacer**

Bases: *SequenceWalker*

Replaces nodes in a node with new nodes based on a mapping.

**__init__**(*root*, *replacements*)

**Parameters**

- **root** (BaseNode)
- **replacements** (*dict*)

**Return type**
None

### angr.analyses.decompiler.notes

**class** angr.analyses.decompiler.notes.**DecompilationNote**

Bases: object

Describes a note that is generated during decompilation.

Key is a unique string for the decompilation note. It is used as an index in the decompilation notes dictionary in the Decompiler class. Name is string for display by default. Content is the actual content of the note. It can be of any time, but for custom types, you must override *__str__* so that it can be displayed. Level is the level of the

note. The following values are available: DecompilationNoteLevel.DEBUG, DecompilationNoteLevel.INFO, DecompilationNoteLevel.WARNING, and DecompilationNoteLevel.CRITICAL.

**__init__**(*key*, *name*, *content*, *, *level=DecompilationNoteLevel.INFO*)

**Parameters**

- **key** (*str*)
- **name** (*str*)
- **content** (*Any*)

**key**

**name**

**content**

**level**

**to_jsonable**()

**Return type**
dict[str, Any]

**to_json**()

**Return type**
str

**classmethod from_jsonable**(*d*)

**Return type**
*DecompilationNote*

**Parameters**
**d** (*dict[str, Any]*)

**classmethod from_json**(*s*)

**Return type**
*DecompilationNote*

**Parameters**
**s** (*str*)

**class** angr.analyses.decompiler.notes.**DecompilationNoteLevel**

Bases: Enum

Enum class describing the level of each decompilation note.

**DEBUG = 0**

**INFO = 1**

**WARNING = 2**

**CRITICAL = 3**

**class** angr.analyses.decompiler.notes.**DeobfuscatedString**

Bases: object

Represents a deobfuscated string.

__init__(*value*, *obf_type*, *ref_addr=None*)

**Parameters**

- **value** (bytes)
- **obf_type** (*str*)
- **ref_addr** (*int | None*)

**value**

**type**

**ref_addr**

class angr.analyses.decompiler.notes.**DeobfuscatedStringsNote**

Bases: *DecompilationNote*

Represents a decompilation note that describes obfuscated strings found during decompilation.

__init__(*key='deobfuscated_strings'*, *name='Deobfuscated Strings'*)

**Parameters**

- **key** (*str*)
- **name** (*str*)

**strings: dict[int, *DeobfuscatedString*]**

**add_string**(*obf_type*, *value*, ***, *ref_addr*)

Add a deobfuscated string to the note.

**Parameters**

- **obf_type** (str) – The type of obfuscation (e.g., “1”, “2”).
- **value** (bytes) – The deobfuscated string value.
- **ref_addr** (int) – The address where this string is referenced, if applicable.

**to_jsonable**()

**Return type**

dict[str, Any]

**content**

**key**

**level**

**name**

## Submodules

classmethod **from_json**(*s*)

**Return type**
*DecompilationNote*

**Parameters**
**s** (*str*)

### angr.analyses.decompiler.notes.deobfuscated_strings

class angr.analyses.decompiler.notes.deobfuscated_strings.**DeobfuscatedString**

Bases: object

Represents a deobfuscated string.

**__init__**(*value*, *obf_type*, *ref_addr=None*)

**Parameters**

- **value** (bytes)
- **obf_type** (*str*)
- **ref_addr** (*int | None*)

**value**

**type**

**ref_addr**

class angr.analyses.decompiler.notes.deobfuscated_strings.**DeobfuscatedStringsNote**

Bases: *DecompilationNote*

Represents a decompilation note that describes obfuscated strings found during decompilation.

**__init__**(*key='deobfuscated_strings'*, *name='Deobfuscated Strings'*)

**Parameters**

- **key** (*str*)
- **name** (*str*)

**strings:** dict[int, *DeobfuscatedString*]

**add_string**(*obf_type*, *value*, ***, *ref_addr*)

Add a deobfuscated string to the note.

**Parameters**

- **obf_type** (str) – The type of obfuscation (e.g., “1”, “2”).
- **value** (bytes) – The deobfuscated string value.
- **ref_addr** (int) – The address where this string is referenced, if applicable.

**to_jsonable**()

**Return type**
dict[str, Any]

**content**

**key**

**level**

**name**

### angr.analyses.decompiler.optimization_pass_registry

Stable name resolution for decompiler optimization passes and peephole optimizations.

angr.analyses.decompiler.optimization_pass_registry.**name_to_pass**(*name*)

Resolve a class name back to its registered pass class. Returns None for names that are not registered at the time this method is called. Peephole passes might be defined by analyses or plugins that have not yet been imported.

**Return type**
type | None

**Parameters**
**name** (*str*)

angr.analyses.decompiler.optimization_pass_registry.**pass_to_name**(*cls*)

Return a stable string identifier (the class name) for an optimization pass or peephole class.

**Return type**
str

**Parameters**
**cls** (type)

### angr.analyses.decompiler.optimization_passes

**class** angr.analyses.decompiler.optimization_passes.**BasePointerSaveSimplifier**

Bases: *OptimizationPass*

Removes the effects of base pointer stack storage at function invocation and restoring at function return.

**ARCHES = ['X86', 'AMD64', 'ARMEL', 'ARMHF', 'ARMCortexM', 'MIPS32', 'MIPS64']**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 6**

**NAME = 'Simplify base pointer saving'**

**DESCRIPTION = 'Removes the effects of base pointer stack storage at function invocation and restoring at function return.'**

**__init__**(**args*, ***kwargs*)

**class** angr.analyses.decompiler.optimization_passes.**CallStatementRewriter**

Bases: *OptimizationPass*

Rewrite call statements to assignments if needed.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 5**

**NAME = 'Unify call statements on demand.'**

**DESCRIPTION = 'Rewrite call statements to assignments if needed.'**

**__init__**(**args*, ***kwargs*)

**class** angr.analyses.decompiler.optimization_passes.**CmpFValueLowering**

Bases: *SequenceOptimizationPass*

Lowers CmpF results that survive as values (e.g., an x87 status word stored by fnstsw) into exact IEEE C. Runs after all predicate folding, so it only sees CmpF values that no flag test consumed.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 11**

**NAME = 'Lower CmpF values'**

**DESCRIPTION = 'Lowers CmpF results that survive as values (e.g., an x87 status word stored by fnstsw) into exact IEEE C. Runs after\n all predicate folding, so it only sees CmpF values that no flag test consumed.'**

**__init__**(**args*, ***kwargs*)

**class** angr.analyses.decompiler.optimization_passes.**CodeMotionOptimization**

Bases: *OptimizationPass*

Moves common statements out of blocks that share the same predecessors or the same successors. This is done to reduce the number of statements in a block and to make the blocks more similar to each other.

As an example:

```
if (x) {
    b = 2;
    a = 1;
    c = 3;
} else {
    b = 2;
    c = 3;
}
```

Will be turned into:

```
if (x) {
    a = 1;
}
b = 2;
c = 3;
```

Current limitations (for very conservative operations):

- moving statements above conditional jumps is not supported
- only immediate children and parents are considered for moving statements
- when moving statements down, a block is only considered if already has a matching statement at the end

**ARCHES = None**

**PLATFORMS = None**

**NAME = 'Merge common statements in sub-scopes'**

**STAGE: *OptimizationPassStage* = 6**

**DESCRIPTION = '\n Moves common statements out of blocks that share the same predecessors or the same\n successors. This is done to reduce the number of statements in a block and to make the\n blocks more similar to each other.\n\n As an example::\n\n if (x) {\n b = 2;\n a = 1;\n c = 3;\n } else {\n b = 2;\n c = 3;\n }\n\n Will be turned into::\n\n if (x) {\n a = 1;\n }\n b = 2;\n c = 3;\n\n Current limitations (for very conservative operations):\n\n - moving statements above conditional jumps is not supported\n - only immediate children and parents are considered for moving statements\n - when moving statements down, a block is only considered if already has a matching statement at the end\n '**

**__init__**(**args*, *max_iters=10*, *node_idx_start=1*, ***kwargs*)

**Parameters**
**node_idx_start** (*int*)

**static update_graph_with_super_edits**(*original_graph*, *super_graph*, *updated_blocks*)

This function updates an graph when doing block edits on a supergraph version of that same graph. The updated blocks must be provided as a dictionary where the keys are original block in the supergraph and the values are the new blocks that should replace them.

The supergraph MUST be generated using the to_ail_supergraph function, since it stores the original nodes each super node represents. This is necessary to update the original graph with the new super nodes.

**Return type**
bool

**Parameters**

- **original_graph** (*DiGraph*)
- **super_graph** (*DiGraph*)
- **updated_blocks** (*dict[Block, Block]*)

**class** angr.analyses.decompiler.optimization_passes.**ConditionConstantPropagation**

Bases: *OptimizationPass*

Reason about constant propagation opportunities from conditionals and propagate constants in the graph accordingly.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 2**

**NAME = 'Propagate constants using information deduced from conditionals.'**

**DESCRIPTION = 'Reason about constant propagation opportunities from conditionals and propagate constants in the graph accordingly.'**

**__init__**(**args*, ***kwargs*)

class angr.analyses.decompiler.optimization_passes.**ConstPropOptReverter**

Bases: *OptimizationPass*

This optimization reverts the effects of constant propagation done by the compiler as discussed in the USENIX 2024 paper SAILR. This optimization's main goal is to enable later optimizations that rely on symbolic variables to be more effective. This optimization pass will convert two statements with a difference of a const and a symbolic variable into two statements with the symbolic variables.

As an example: x = 75 puts(x) puts(75)

will be converted to: x = 75 puts(x) puts(x)

**ARCHES = None**

**DESCRIPTION = 'Makes the following simplifications::\n\n *(*(const_addr)) ==>
*(value) iff *const_addr == value'**

**__init__**(**args*, ***kwargs*)

class angr.analyses.decompiler.optimization_passes.**CrossJumpReverter**

Bases: *StructuringOptimizationPass*

This is an implementation to revert the compiler optimization Cross Jumping, an ISC optimization discussed in the USENIX 2024 paper SAILR. This optimization is somewhat aggressive and as such should be run last in your decompiler deoptimization chain. This deoptimization will take any goto it finds and attempt to duplicate its target block if its target only has one outgoing edge.

There are some heuristics in place to prevent duplication everywhere. First, this deoptimization will only run a max of max_opt_iters times. Second, it will not duplicate a block with too many calls.

**STAGE: *OptimizationPassStage* = 10**

**NAME = 'Duplicate linear blocks with gotos'**

**DESCRIPTION = 'This is an implementation to revert the compiler optimization Cross Jumping, an ISC optimization discussed\nin the USENIX 2024 paper SAILR. This optimization is somewhat aggressive and as such should be run last in your\ndecompiler deoptimization chain. This deoptimization will take any goto it finds and attempt to duplicate its\ntarget block if its target only has one outgoing edge.\n\nThere are some heuristics in place to prevent duplication everywhere. First, this deoptimization will only run\na max of max_opt_iters times. Second, it will not duplicate a block with too many calls.'**

**__init__**(**args*, *node_idx_start=1*, *max_opt_iters=3*, *max_call_duplications=1*, ***kwargs*)

**Parameters**

- **node_idx_start** (*int*)
- **max_opt_iters** (*int*)
- **max_call_duplications** (*int*)

class angr.analyses.decompiler.optimization_passes.**DeadblockRemover**

Bases: *OptimizationPass*

Removes condition-unreachable blocks from the graph.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 9**

**NAME = 'Remove blocks with unsatisfiable conditions'**

**DESCRIPTION = 'Removes condition-unreachable blocks from the graph.'**

**__init__**(**args*, *node_cutoff=200*, ***kwargs*)

**Parameters**

**node_cutoff** (*int*)

class angr.analyses.decompiler.optimization_passes.**DivSimplifier**

Bases: *OptimizationPass*

Simplifies various division optimizations back to “div”.

**ARCHES = ['X86', 'AMD64', 'ARMCortexM', 'ARMHF', 'ARMEL']**

**PLATFORMS = None**

**STAGE:** *OptimizationPassStage* **= 6**

**NAME = 'Simplify arithmetic division'**

**DESCRIPTION = 'Simplifies various division optimizations back to "div".'**

**__init__**(**args*, ***kwargs*)

**class** angr.analyses.decompiler.optimization_passes.**DuplicationReverter**

Bases: *StructuringOptimizationPass*

This (de)optimization reverts the effects of many compiler optimizations that cause code duplication in the decompilation. This deoptimization is the implementation of the USENIX 2024 paper SAILR's ISD doptimization. As such, the main goal of this optimization is to remove code duplication by merging semantically similar blocks in the AIL graph.

**NAME = 'Revert Statement Duplication Optimizations'**

**DESCRIPTION = "This (de)optimization reverts the effects of many compiler optimizations that cause code duplication in\n the decompilation. This deoptimization is the implementation of the USENIX 2024 paper SAILR's ISD\n doptimization. As such, the main goal of this optimization is to remove code duplication by merging\n semantically similar blocks in the AIL graph."**

**__init__**(**args*, *max_guarding_conditions=4*, ***kwargs*)

**static boolean_operators_in_condition**(*condition*)

TODO: this entire boolean checking semantic we use needs to be removed, see how it is used for other dels needed we need to replace it with a boolean variable insertion on both branches that lead to the new block.

Say we have:

```
if (A()) {
    do_thing();
}
if (B()) {
    do_thing():
}
```

We want to translate it to:

```
int should_do_thing = 0;
if (A())
    should_do_thing = 1;
if (B())
    should_do_thing = 1;

if (should_do_thing):
    do_thing();
```

Although longer, this code can be optimized to look like:

```
int should_do_thing = A() || B();
if (should_do_thing)
    do_thing();
```

**Parameters**
**condition** (Expression)

**stmt_can_move_to**(*stmt*, *block*, *new_idx*, *io_finder=None*)

**maximize_similarity_of_blocks**(*block1*, *block2*, *graph*)

This attempts to rearrange the order of statements in block1 and block2 to maximize the similarity between them. This implementation is a little outdated since CodeMotion optimization was implemented, but it should be disabled until we have a good SSA implementation.

TODO: reimplement me when we have better SSA

**Return type**
tuple[Block, Block]

**create_merged_subgraph**(*blocks*, *graph*, *maximize_similarity=False*)

**Return type**
*AILMergeGraph*

**Parameters**
**graph** (*DiGraph*)

**similar_conditional_when_single_corrected**(*block1*, *block2*, *graph*)

**Parameters**

- **block1** (*Block*)
- **block2** (*Block*)
- **graph** (*DiGraph*)

**collect_conditions_between_nodes**(*graph*, *source*, *sinks*, *max_depth=15*)

**Parameters**

- **source** (*Block*)
- **sinks** (*list[Block]*)

**shared_common_conditional_dom**(*nodes*, *graph*)

Takes n nodes and returns True only if all the nodes are dominated by the same node, which must be a ConditionalJump

@param nodes: @param graph: @return:

**Parameters**
**graph** (*DiGraph*)

class angr.analyses.decompiler.optimization_passes.**EagerStdStringConcatenationPass**

**class** angr.analyses.decompiler.optimization_passes.**Float128PairCoalescer**

Bases: *OptimizationPass*

Coalesce binary128 (long double) values that VEX splits across a pair of 64-bit FP registers.

s390x keeps a long double in a register pair (f0:f2, f4:f6, ...). VEX reads it with F64HLtoF128(hi, lo) and writes it back with F128HItoF64 / F128LOtoF64, so every long double turns into two 64-bit halves that are concatenated at each use. This pass gives each such pair one 128-bit variable, defined by the 128-bit operation that produced the halves or by one 16-byte load, and rewrites the uses: concatenations, stores of both halves, and spills of both halves to adjacent stack slots. 128-bit constants built from two 64-bit halves are folded too.

**ARCHES = ['S390X']**

**PLATFORMS = None**

STAGE: *OptimizationPassStage* = 6

NAME = 'Coalesce binary128 register pairs'

DESCRIPTION = 'Coalesce binary128 (long double) values that VEX splits across a pair of 64-bit FP registers.\n\n s390x keeps a long double in a register pair (f0:f2, f4:f6, ...). __init__(*func*, **args*, ***kwargs*)

class angr.analyses.decompiler.optimization_passes.**FpNegation**

Bases: *OptimizationPass*

Rewrite floating-point sign-bit XORs (xorps/xorpd) into negation.

The lifter cannot tell an FP sign flip from an arbitrary 128-bit integer XOR with a sign-shaped constant; both produce the same AIL. This pass only rewrites when the XORed value is provably floating-point: it lives in an FP argument register of the prototype, or has FP provenance in the expression (FP conversions and operations, traced through local definitions).

It runs right before variable recovery, ahead of KnownPatternOutliner (which would otherwise outline the XOR as an opaque fneg() call), so Typehoon sees a floating-point negation instead of an integer XOR.

ARCHES = ['X86', 'AMD64']

PLATFORMS = ['linux', 'windows']

STAGE: *OptimizationPassStage* = 7

NAME = 'Rewrite FP sign-bit XOR to negation'

DESCRIPTION = 'Rewrite floating-point sign-bit XORs (``xorps``/``xorpd``) into negation.\n\n The lifter cannot tell an FP sign flip from an arbitrary 128-bit integer\n XOR with a sign-shaped constant; both produce the same AIL. **__init__**(*func*, *manager*, *known_patterns=None*, *recognize_known_patterns=True*, ***kwargs*)

**class** angr.analyses.decompiler.optimization_passes.**LoweredSwitchSimplifier**

Bases: *StructuringOptimizationPass*

This optimization recognizes and reverts switch cases that have been lowered and possibly split into multiple if-else statements. This optimization, discussed in the USENIX 2024 paper SAILR, aims to undo the compiler optimization known as "Switch Lowering", present in both GCC and Clang. An in-depth discussion of this optimization can be found in the paper or in our documentation of the optimization: https://github.com/mahaloz/sailr-eval/issues/14#issue-2232616411

Note, this optimization does not occur in MSVC, which uses a different optimization strategy for switch cases. As a hack for now, we only run this deoptimization on Linux binaries.

**PLATFORMS = ['linux']**

**NAME = 'Convert lowered switch-cases (if-else) to switch-cases'**

**DESCRIPTION = 'Convert lowered switch-cases (if-else) to switch-cases. Only works when the Phoenix structuring algorithm is in use.'**

__init__(**args*, ***kwargs*)

class angr.analyses.decompiler.optimization_passes.**OptimizationPassStage**

Bases: Enum

Enums about optimization pass stages.

Note that the region identification pass (RegionIdentifier) may modify existing AIL blocks *without updating the topology of the original AIL graph*. For example, loop successor refinement may modify create a new AIL block with an artificial address, and alter existing jump targets of jump statements and conditional jump statements to point to this new block. However, loop successor refinement does not update the topology of the original AIL graph, which means this new AIL block does not exist in the original AIL graph. As a result, until this behavior of RegionIdentifier changes in the future, DURING_REGION_IDENTIFICATION optimization passes should not modify existing jump targets.

a single-entry sub-run of an occurrence must cover this share of its tokens to be outlined under the pattern's name

**__init__**(*func*, *manager*, ***kwargs*)

**outlined: list[tuple[str, tuple[int, int], float]]**

(pattern name, block location of the call, share of the occurrence's tokens covered) for every occurrence outlined; the share is below 1 when only a sub-run could be

**skipped: list[tuple[str, str]]**

(pattern name, reason) for every occurrence that was found but not outlined

**lossy: list[tuple[str, tuple[int, int], int]]**

(pattern name, call location, values dropped) for every occurrence outlined although the region leaves more values live than the call can return: the output there is wrong

**new_block_addr**()

A block address no block of the graph being rewritten has.

The base class allocates from a map of the blocks built once per stage, before any pass of the stage ran, so it hands out addresses an earlier pass of this stage (the KnownPatternOutliner, say) has already given its own new blocks; the outline is then rolled back as a duplicate block location.

**Return type**
int

class angr.analyses.decompiler.optimization_passes.**RegisterSaveAreaSimplifier**

Bases: *OptimizationPass*

Optimizes away register spilling effects, including callee-saved registers.

This optimization runs between SSA-level0 and SSA-level1, which means registers are converted to vvars but stack accesses stay unchanged.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 2**

**NAME = 'Simplify register save areas'**

**DESCRIPTION = 'Optimizes away register spilling effects, including callee-saved registers.\n\n This optimization runs between SSA-level0 and SSA-level1, which means registers are converted to vvars but stack\n accesses stay unchanged.'**

**__init__**(**args*, ***kwargs*)

class angr.analyses.decompiler.optimization_passes.**RegisterSaveAreaSimplifierAdvanced**

Bases: *OptimizationPass*

Optimizes away registers that are stored to or restored on the stack space.

This analysis is more complex than RegisterSaveAreaSimplifier because it handles: (1) Registers that are stored in the stack shadow space (sp+N) according to the Windows x64 calling convention. (2) Registers that are aliases of sp.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 5**

**NAME = 'Simplify register save areas (advanced)'**

**DESCRIPTION = 'Optimizes away registers that are stored to or restored on the stack space.\n\n This analysis is more complex than RegisterSaveAreaSimplifier because it handles:\n (1) Registers that are stored in the stack shadow space (sp+N) according to the Windows x64 calling convention.\n (2) Registers that are aliases of sp.'**

**__init__**(**args*, ***kwargs*)

class angr.analyses.decompiler.optimization_passes.**RetAddrSaveSimplifier**

Bases: *OptimizationPass*

Removes code in function prologues and epilogues for saving and restoring return address registers (ra, lr, etc.), generally seen in non-leaf functions.

**ARCHES = ['MIPS32', 'MIPS64']**

**PLATFORMS = ['linux']**

**STAGE: *OptimizationPassStage* = 6**

**NAME = 'Simplify return address storage'**

**DESCRIPTION = 'Removes code in function prologues and epilogues for saving and restoring return address registers (ra, lr, etc.),\n generally seen in non-leaf functions.'**

**__init__**(**args*, ***kwargs*)

**class** angr.analyses.decompiler.optimization_passes.**ReturnDeduplicator**

Bases: *OptimizationPass*

Transforms: - if (cond) { … return x; } return x;

into: - if (cond) { … } return x;

TODO: its possible that this can be expanded to all rets that are equivalent. Testing needed.

**ARCHES = ['X86', 'AMD64', 'ARMEL', 'ARMHF', 'ARMCortexM', 'MIPS32', 'MIPS64']**

**PLATFORMS = ['windows', 'linux', 'cgc']**

**STAGE: *OptimizationPassStage* = 10**

**NAME = 'Deduplicates return statements that may have been duplicated'**

**DESCRIPTION = 'Transforms:\n - if (cond) { ... return x; } return x;\n\n into:\n - if (cond) { ... } return x;\n\n TODO: its possible that this can be expanded to all rets that are equivalent. Testing needed.'**

**STRUCTURING: list[str] | None = ['sailr', 'dream']**

**__init__**(**args*, ***kwargs*)

**class** angr.analyses.decompiler.optimization_passes.**ReturnDuplicatorHigh**

Bases: *OptimizationPass*, *ReturnDuplicatorBase*

This is a light-level goto-less version of the ReturnDuplicator optimization pass. It will only duplicate return-only blocks.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 6**

**NAME = 'Duplicate return-only blocks (high)'**

**DESCRIPTION = '\n This is a light-level goto-less version of the ReturnDuplicator optimization pass. It will only\n duplicate return-only blocks.\n '**

**STRUCTURING: list[str] | None = ['sailr', 'dream']**

**__init__**(**args*, *vvar_id_start*, *max_calls_in_regions=2*, *minimize_copies_for_regions=True*, *scratch=None*, ***kwargs*)

**Parameters**

- **max_calls_in_regions** (*int*)
- **minimize_copies_for_regions** (*bool*)
- **scratch** (*dict[str, Any] | None*)

class angr.analyses.decompiler.optimization_passes.**ReturnDuplicatorLow**

Bases: *StructuringOptimizationPass*, *ReturnDuplicatorBase*

An optimization pass that reverts a subset of Irreducible Statement Condensing (ISC) optimizations, as described in the USENIX 2024 paper SAILR. This is the heavy/goto version of the ReturnDuplicator optimization pass.

Some compilers, including GCC, Clang, and MSVC, apply various optimizations to reduce the number of statements in code. These optimizations will take equivalent statements, or a subset of them, and replace them with a single copy that is jumped to by gotos – optimizing for space and sometimes speed.

This optimization pass will revert those gotos by re-duplicating the condensed blocks. Since Return statements are the most common, we use this optimization pass to revert only gotos to return statements. Additionally, we perform some additional readability fixups, like not re-duplicating returns to shared components.

**Parameters**

- **func** – The function to optimize.
- **node_idx_start** – The index to start at when creating new nodes. This is used by Clinic to ensure that node indices are unique across multiple passes.
- **max_opt_iters** (int) – The maximum number of optimization iterations to perform.
- **max_calls_in_regions** (int) – The maximum number of calls that can be in a region. This is used to prevent duplicating too much code.
- **prevent_new_gotos** (bool) – If True, this optimization pass will prevent new gotos from being created.
- **minimize_copies_for_regions** (bool) – If True, this optimization pass will minimize the number of copies by doing only a single copy for connected in_edges that form a region.

**ARCHES = None**

**PLATFORMS = None**

**NAME = 'Duplicate returns connect with gotos (low)'**

### angr.analyses.decompiler.optimization_passes.base_ptr_save_simplifier

**class** angr.analyses.decompiler.optimization_passes.base_ptr_save_simplifier.**BasePointerSaveSimplifier**

Bases: *OptimizationPass*

Removes the effects of base pointer stack storage at function invocation and restoring at function return.

**ARCHES = ['X86', 'AMD64', 'ARMEL', 'ARMHF', 'ARMCortexM', 'MIPS32', 'MIPS64']**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 6**

**NAME = 'Simplify base pointer saving'**

**DESCRIPTION = 'Removes the effects of base pointer stack storage at function invocation and restoring at function return.'**

**__init__**(**args*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.call_stmt_rewriter

**class** angr.analyses.decompiler.optimization_passes.call_stmt_rewriter.**CallStatementRewriter**

Bases: *OptimizationPass*

Rewrite call statements to assignments if needed.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 5**

**NAME = 'Unify call statements on demand.'**

**DESCRIPTION = 'Rewrite call statements to assignments if needed.'**

**__init__**(**args*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.cmpf_value_lowering

**class** angr.analyses.decompiler.optimization_passes.cmpf_value_lowering.**CmpFValueLowering**

Bases: *SequenceOptimizationPass*

Lowers CmpF results that survive as values (e.g., an x87 status word stored by fnstsw) into exact IEEE C. Runs after all predicate folding, so it only sees CmpF values that no flag test consumed.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 11**

**NAME = 'Lower CmpF values'**

**DESCRIPTION = 'Lowers CmpF results that survive as values (e.g., an x87 status word stored by fnstsw) into exact IEEE C. Runs after\n all predicate folding, so it only sees CmpF values that no flag test consumed.'**

**__init__**(**args*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.code_motion

**class** angr.analyses.decompiler.optimization_passes.code_motion.**CodeMotionOptimization**

Bases: *OptimizationPass*

Moves common statements out of blocks that share the same predecessors or the same successors. This is done to reduce the number of statements in a block and to make the blocks more similar to each other.

As an example:

```
if (x) {
    b = 2;
    a = 1;
    c = 3;
} else {
    b = 2;
```

(continues on next page)

(continued from previous page)

```
    c = 3;
}
```

Will be turned into:

```
if (x) {
    a = 1;
}
b = 2;
c = 3;
```

Current limitations (for very conservative operations):

- moving statements above conditional jumps is not supported
- only immediate children and parents are considered for moving statements
- when moving statements down, a block is only considered if already has a matching statement at the end

**ARCHES = None**

**PLATFORMS = None**

**NAME = 'Merge common statements in sub-scopes'**

**STAGE: *OptimizationPassStage* = 6**

**DESCRIPTION = '\n Moves common statements out of blocks that share the same predecessors or the same\n successors. This is done to reduce the number of statements in a block and to make the\n blocks more similar to each other.\n\n As an example::\n\n if (x) {\n b = 2;\n a = 1;\n c = 3;\n } else {\n b = 2;\n c = 3;\n }\n\n Will be turned into::\n\n if (x) {\n a = 1;\n }\n b = 2;\n c = 3;\n\n Current limitations (for very conservative operations):\n\n - moving statements above conditional jumps is not supported\n - only immediate children and parents are considered for moving statements\n - when moving statements down, a block is only considered if already has a matching statement at the end\n '**

**__init__**(**args*, *max_iters=10*, *node_idx_start=1*, ***kwargs*)

**Parameters**
**node_idx_start** (*int*)

**static update_graph_with_super_edits**(*original_graph*, *super_graph*, *updated_blocks*)

This function updates an graph when doing block edits on a supergraph version of that same graph. The updated blocks must be provided as a dictionary where the keys are original block in the supergraph and the values are the new blocks that should replace them.

The supergraph MUST be generated using the to_ail_supergraph function, since it stores the original nodes each super node represents. This is necessary to update the original graph with the new super nodes.

**Return type**
bool

**Parameters**

- **original_graph** (*DiGraph*)
- **super_graph** (*DiGraph*)
- **updated_blocks** (*dict[Block, Block]*)

### angr.analyses.decompiler.optimization_passes.combo_register_rewriter

**class** angr.analyses.decompiler.optimization_passes.combo_register_rewriter.**ComboRegisterRewriter**

Bases: *OptimizationPass*, *SRDAMixin*

Rewrite return expressions for calls to functions returning several values via multiple registers.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Rewrite return expressions for calls to functions returning several values via multiple registers'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.condition_constprop

**class** angr.analyses.decompiler.optimization_passes.condition_constprop.**ConstantCondition**

Bases: object

Describes an opportunity for replacing a vvar with a constant value.

**__init__**(*vvar_id*, *value*, *block_addr*, *block_idx*)

**Parameters**

- **vvar_id** (*int*)
- **value** (Const)
- **block_addr** (*int*)
- **block_idx** (*int*)

**class** angr.analyses.decompiler.optimization_passes.condition_constprop.**CCondPropBlockWalker**

Bases: *AILBlockRewriter*

Block walker for ConditionConstantPropagation to replace vvars with constant values.

**__init__**(*vvar_id*, *const_value*)

**Parameters**

- **vvar_id** (*int*)
- **const_value** (Const)

**class** angr.analyses.decompiler.optimization_passes.condition_constprop.**ConditionConstantPropagation**

Bases: *OptimizationPass*

Reason about constant propagation opportunities from conditionals and propagate constants in the graph accordingly.

**ARCHES = None**

**PLATFORMS = None**

**STAGE:** *OptimizationPassStage* **= 2**

**NAME = 'Propagate constants using information deduced from conditionals.'**

**DESCRIPTION = 'Reason about constant propagation opportunities from conditionals and propagate constants in the graph accordingly.'**

**__init__**(**args*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.const_derefs

**class** angr.analyses.decompiler.optimization_passes.const_derefs.**BlockWalker**

Bases: *AILBlockRewriter*

AIL Block walker in order to perform const deref substitution

**__init__**(*project*, *manager*)

**Parameters**

- **project** (Project)
- **manager** (*Manager*)

**class** angr.analyses.decompiler.optimization_passes.const_derefs.**ConstantDereferencesSimplifier**

Bases: *OptimizationPass*

Makes the following simplifications:

```
*(*(const_addr))  ==>  *(value) iff  *const_addr == value
```

**ARCHES = None**

**PLATFORMS = None**

**STAGE:** *OptimizationPassStage* **= 2**

**NAME = 'Simplify constant dereferences'**

**DESCRIPTION = 'Makes the following simplifications::\n\n *(*(const_addr)) ==> *(value) iff *const_addr == value'**

**__init__**(**args*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.const_prop_reverter

**class** angr.analyses.decompiler.optimization_passes.const_prop_reverter.**BlockWalker**

Bases: *AILBlockViewer*

**__init__**(*walked_objs*)

**Parameters**

**walked_objs** (*dict*[type, *set*[SideEffectStatement | Assignment | Return | Store]])

class angr.analyses.decompiler.optimization_passes.const_prop_reverter.**ConstPropOptReverter**

Bases: *OptimizationPass*

This optimization reverts the effects of constant propagation done by the compiler as discussed in the USENIX 2024 paper SAILR. This optimization's main goal is to enable later optimizations that rely on symbolic variables to be more effective. This optimization pass will convert two statements with a difference of a const and a symbolic variable into two statements with the symbolic variables.

As an example: x = 75 puts(x) puts(75)

will be converted to: x = 75 puts(x) puts(x)

**ARCHES = None**

**PLATFORMS = None**

**STRUCTURING: list[str] | None = ['sailr', 'dream']**

**STAGE: *OptimizationPassStage* = 10**

**NAME = 'Revert Constant Propagation Optimizations'**

**DESCRIPTION = "This optimization reverts the effects of constant propagation done by the compiler as discussed in the\n USENIX 2024 paper SAILR. **__init__**(**args*, *region_identifier=None*, *reaching_definitions=None*, ***kwargs*)

**static find_conflicting_call_args**(*call0*, *call1*)

**Parameters**

- **call0** (Call)
- **call1** (Call)

## angr.analyses.decompiler.optimization_passes.cross_jump_reverter

class angr.analyses.decompiler.optimization_passes.cross_jump_reverter.**CrossJumpReverter**

Bases: *StructuringOptimizationPass*

This is an implementation to revert the compiler optimization Cross Jumping, an ISC optimization discussed in the USENIX 2024 paper SAILR. This optimization is somewhat aggressive and as such should be run last in your decompiler deoptimization chain. This deoptimization will take any goto it finds and attempt to duplicate its target block if its target only has one outgoing edge.

There are some heuristics in place to prevent duplication everywhere. First, this deoptimization will only run a max of max_opt_iters times. Second, it will not duplicate a block with too many calls.

**STAGE: *OptimizationPassStage* = 10**

**NAME = 'Duplicate linear blocks with gotos'**

DESCRIPTION = 'This is an implementation to revert the compiler optimization Cross Jumping, an ISC optimization discussed\nin the USENIX 2024 paper SAILR. This optimization is somewhat aggressive and as such should be run last in your\ndecompiler deoptimization chain. This deoptimization will take any goto it finds and attempt to duplicate its\ntarget block if its target only has one outgoing edge.\n\nThere are some heuristics in place to prevent duplication everywhere. First, this deoptimization will only run\na max of max_opt_iters times. Second, it will not duplicate a block with too many calls.'

__init__(**args*, *node_idx_start=1*, *max_opt_iters=3*, *max_call_duplications=1*, ***kwargs*)

**Parameters**

- **node_idx_start** (*int*)
- **max_opt_iters** (*int*)
- **max_call_duplications** (*int*)

### angr.analyses.decompiler.optimization_passes.deadblock_remover

class angr.analyses.decompiler.optimization_passes.deadblock_remover.**DeadblockRemover**

Bases: *OptimizationPass*

Removes condition-unreachable blocks from the graph.

ARCHES = None

PLATFORMS = None

STAGE: *OptimizationPassStage* = 9

NAME = 'Remove blocks with unsatisfiable conditions'

DESCRIPTION = 'Removes condition-unreachable blocks from the graph.'

__init__(**args*, *node_cutoff=200*, ***kwargs*)

**Parameters**

**node_cutoff** (*int*)

### angr.analyses.decompiler.optimization_passes.determine_load_sizes

class angr.analyses.decompiler.optimization_passes.determine_load_sizes.**LoadSizeRewriter**

Bases: *AILBlockRewriter*

Rewrite Load expressions whose sizes are undetermined into loads of the strings they point to.

__init__(*project*)

**Parameters**

**project** (Project)

class angr.analyses.decompiler.optimization_passes.determine_load_sizes.**DetermineLoadSizes**

Bases: *OptimizationPass*

Determine the sizes of Load expressions whose sizes are undetermined.

ARCHES = None

PLATFORMS = None

STAGE: *OptimizationPassStage* = 6

NAME = 'Determine sizes of loads whose sizes are undetermined'

DESCRIPTION = 'Determine the sizes of Load expressions whose sizes are undetermined.'

__init__(**args*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.div_simplifier

class angr.analyses.decompiler.optimization_passes.div_simplifier.**DivSimplifierAILEngine**

Bases: *SimplifierAILEngine*

An AIL pass for the div simplifier

__init__(*project*, *manager*)

class angr.analyses.decompiler.optimization_passes.div_simplifier.**DivSimplifier**

Bases: *OptimizationPass*

Simplifies various division optimizations back to "div".

ARCHES = ['X86', 'AMD64', 'ARMCortexM', 'ARMHF', 'ARMEL']

PLATFORMS = None

STAGE: *OptimizationPassStage* = 6

NAME = 'Simplify arithmetic division'

DESCRIPTION = 'Simplifies various division optimizations back to "div".'

__init__(**args*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.duplication_reverter

class angr.analyses.decompiler.optimization_passes.duplication_reverter.**DuplicationReverter**

Bases: *StructuringOptimizationPass*

This (de)optimization reverts the effects of many compiler optimizations that cause code duplication in the decompilation. This deoptimization is the implementation of the USENIX 2024 paper SAILR's ISD doptimization. As such, the main goal of this optimization is to remove code duplication by merging semantically similar blocks in the AIL graph.

NAME = 'Revert Statement Duplication Optimizations'

DESCRIPTION = "This (de)optimization reverts the effects of many compiler optimizations that cause code duplication in\n the decompilation. This deoptimization is the implementation of the USENIX 2024 paper SAILR's ISD\n doptimization. As such, the main goal of this optimization is to remove code duplication by merging\n semantically similar blocks in the AIL graph."

__init__(**args*, *max_guarding_conditions=4*, ***kwargs*)

**write_graph:** DiGraph | None

**read_graph:** DiGraph | None

**static boolean_operators_in_condition**(*condition*)

TODO: this entire boolean checking semantic we use needs to be removed, see how it is used for other dels needed we need to replace it with a boolean variable insertion on both branches that lead to the new block.

Say we have:

```
if (A()) {
    do_thing();
}
if (B()) {
    do_thing():
}
```

We want to translate it to:

```
int should_do_thing = 0;
if (A())
    should_do_thing = 1;
if (B())
    should_do_thing = 1;

if (should_do_thing):
    do_thing();
```

Although longer, this code can be optimized to look like:

```
int should_do_thing = A() || B();
if (should_do_thing)
    do_thing();
```

**Parameters**
**condition** (Expression)

**stmt_can_move_to**(*stmt*, *block*, *new_idx*, *io_finder=None*)

**maximize_similarity_of_blocks**(*block1*, *block2*, *graph*)

This attempts to rearrange the order of statements in block1 and block2 to maximize the similarity between them. This implementation is a little outdated since CodeMotion optimization was implemented, but it should be disabled until we have a good SSA implementation.

TODO: reimplement me when we have better SSA

**Return type**
tuple[Block, Block]

**create_merged_subgraph**(*blocks*, *graph*, *maximize_similarity=False*)

**Return type**
*AILMergeGraph*

**Parameters**
**graph** (*DiGraph*)

**similar_conditional_when_single_corrected**(*block1*, *block2*, *graph*)

**Parameters**

- **block1** (*Block*)
- **block2** (*Block*)
- **graph** (*DiGraph*)

**collect_conditions_between_nodes**(*graph*, *source*, *sinks*, *max_depth=15*)

**Parameters**

- **source** (*Block*)
- **sinks** (*list[Block]*)

**shared_common_conditional_dom**(*nodes*, *graph*)

Takes n nodes and returns True only if all the nodes are dominated by the same node, which must be a ConditionalJump

@param nodes: @param graph: @return:

**Parameters**
**graph** (*DiGraph*)

## Submodules

*ail_merge_graph*
*duplication_reverter*
*errors*
*similarity*
*utils*

### angr.analyses.decompiler.optimization_passes.duplication_reverter.ail_merge_graph

**class** angr.analyses.decompiler.optimization_passes.duplication_reverter.ail_merge_graph.**AILBlockSplit**

Bases: object

This class represents a block that has been split into three parts, which is best explained in the AILMergeGraph class example. See that class for more information.

The up_split, is all statements above the matched Longest Common Sequence (LCS), the match_split is the LCS, and the down_split is all statements below the matched LCS. This class should only be used in the context of the AILMergeGraph class.

**__init__**(*original=None*, *up_split=None*, *match_split=None*, *down_split=None*)

**Parameters**

- **original**
- **up_split** – The block split above the matched LCS
- **match_split** – The block containing only the matched LCS
- **down_split** – The block split below the matched LCS

**classmethod from_block_lcs**(*original_block*, *idx*, *len_*)

**Parameters**
**original_block** (*Block*)

**static split_ail_block**(*block*, *split_idx*, *split_len*)

**Return type**
tuple[Block | None, Block | None, Block | None]

**class** angr.analyses.decompiler.optimization_passes.duplication_reverter.ail_merge_graph.**AILMergeGraph**

Bases: object

This class represents the merged results of two AIL graphs that have been found to be similar. We can reference these graphs as G1 and G2. The two graphs are of the following form, where any node other than D can be empty:

```
  A
 /           B   C
\  /
 D
/          E   F
```

The D node can be a subgraph, but in both G1 and G2, this D-subgraph are exact duplicates of each other, except their top and bottom statements. This class is the result of merging those two D subgraphs.

To explain that last part about statements differing at the ends, see this example:

```
D1:
-----
a = 10;
puts(a);
puts("bye");
-----

D2:
-----
a = 11;
puts(a);
puts("cya");
-----
```

In this case, the merged D would contain just `puts(a)`. The statements above it, referred to as up_split in the code, and the statements below it, referred to as down_split in the code, would be moved out of the block and bounded by the conditions that lead to those statements. This creates a graph even in the case of a single block being the original D.

Lastly, since this class will deal a lot with splitting blocks into pieces, we keep a mapping of how the original blocks turned into the new ones and vice versa.

**__init__**(*graph=None*, *original_graph=None*, *conditional_block=None*, *original_blocks=None*, *original_split_blocks=None*)

**create_conditionless_graph**(*starting_blocks*, *graph_lcs*)

**Return type**
dict[Block, Block] | None

**Parameters**
**starting_blocks** (*list[Block]*)

**add_edges_to_condition**(*conditional_block*, *true_target*, *merge_end_pairs*)

**create_mapping_to_merge_graph**(*updated_blocks*, *start_blocks*)

**Parameters**

- **updated_blocks** (*dict[Block, Block]*)
- **start_blocks** (*list[Block]*)

**merged_is_split_type**(*merge_block*, *split_type*)

**Parameters**

- **merge_block** (*Block*)
- **split_type** (*str*)

**static clone_graph_replace_splits**(*graph*, *split_map*)

**Parameters**

- **graph** (*DiGraph*)
- **split_map** (*dict[Block, Block]*)

### angr.analyses.decompiler.optimization_passes.duplication_reverter.duplication_reverter

**class** angr.analyses.decompiler.optimization_passes.duplication_reverter.duplication_reverter.**DuplicationReverter**

Bases: *StructuringOptimizationPass*

This (de)optimization reverts the effects of many compiler optimizations that cause code duplication in the decompilation. This deoptimization is the implementation of the USENIX 2024 paper SAILR's ISD doptimization. As such, the main goal of this optimization is to remove code duplication by merging semantically similar blocks in the AIL graph.

**NAME = 'Revert Statement Duplication Optimizations'**

**DESCRIPTION = "This (de)optimization reverts the effects of many compiler optimizations that cause code duplication in\n the decompilation. - **sinks** (*list[Block]*)

**shared_common_conditional_dom**(*nodes*, *graph*)

Takes n nodes and returns True only if all the nodes are dominated by the same node, which must be a ConditionalJump

@param nodes: @param graph: @return:

**Parameters**
**graph** (*DiGraph*)

### angr.analyses.decompiler.optimization_passes.duplication_reverter.errors

**exception** angr.analyses.decompiler.optimization_passes.duplication_reverter.errors.**SAILRSemanticError**

Bases: Exception

These types of errors may not kill the entire analysis, but they do kill the current working round. They are caused when some non-expected state happens, like a ConditionalJump that is not the last statement in a block.

**exception** angr.analyses.decompiler.optimization_passes.duplication_reverter.errors.**UnsupportedAILNodeError**

Bases: *SAILRSemanticError*

These type of errors are raised when an AIL node is not supported by the current implementation. Most common with Switch heads.

### angr.analyses.decompiler.optimization_passes.duplication_reverter.similarity

angr.analyses.decompiler.optimization_passes.duplication_reverter.similarity.**longest_ail_graph_subseq**(*bl*
*gr*

angr.analyses.decompiler.optimization_passes.duplication_reverter.similarity.**ail_graph_similarity**(*block0*
*block1*
*graph*,
*only_b*

**Parameters**

- **block1** (*Block*)
- **graph** (*DiGraph*)

angr.analyses.decompiler.optimization_passes.duplication_reverter.similarity.**ail_similarity_to_orig_bloc**

angr.analyses.decompiler.optimization_passes.duplication_reverter.similarity.**find_block_by_similarity**(*bl*
*gr*
*no*

### angr.analyses.decompiler.optimization_passes.duplication_reverter.utils

angr.analyses.decompiler.optimization_passes.duplication_reverter.utils.**find_block_in_successors_by_addr**

**Return type**
Block | None

**Parameters**

- **addr** (*int*)
- **block** (*Block*)
- **graph** (*DiGraph*)

angr.analyses.decompiler.optimization_passes.duplication_reverter.utils.**replace_node_in_graph**(*graph*, *node*, *replace_with*)

**Parameters**
**graph** (*DiGraph*)

angr.analyses.decompiler.optimization_passes.duplication_reverter.utils.**bfs_list_blocks**(*start_block*, *graph*)

**Parameters**

- **start_block** (*Block*)
- **graph** (*DiGraph*)

angr.analyses.decompiler.optimization_passes.duplication_reverter.utils.**copy_graph_and_nodes**(*graph*)

**Parameters**
**graph** (*DiGraph*)

angr.analyses.decompiler.optimization_passes.duplication_reverter.utils.**ail_block_from_stmts**(*stmts*, *idx=None*, *block_addr=*

**Return type**
Block | None

angr.analyses.decompiler.optimization_passes.duplication_reverter.utils.**deepcopy_ail_jump**(*stmt*, *idx=1*)

**Parameters**
**stmt** (Jump)

angr.analyses.decompiler.optimization_passes.duplication_reverter.utils.**deepcopy_ail_condjump**(*stmt*, *idx=1*)

**Parameters**
**stmt** (ConditionalJump)

angr.analyses.decompiler.optimization_passes.duplication_reverter.utils.**deepcopy_ail_anyjump**(*stmt*, *idx=1*)

**Parameters**
**stmt** (Jump | ConditionalJump)

angr.analyses.decompiler.optimization_passes.duplication_reverter.utils.**correct_jump_targets**(*stmt*, *replacement_map*, *new_stmt=Tr*

**Parameters**
**replacement_map** (*dict[int, int]*)

### angr.analyses.decompiler.optimization_passes.eager_std_string_concatenation

**class** angr.analyses.decompiler.optimization_passes.eager_std_string_concatenation.**EagerStdStringConcatenationPass**

Bases: *OptimizationPass*

Concatenate multiple constant std::string creation calls into one when possible.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Condense multiple constant std::string creation calls into one when possible'**

**DESCRIPTION = 'Concatenate multiple constant std::string creation calls into one when possible.'**

**__init__**(**args*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.eager_std_string_eval

**class** angr.analyses.decompiler.optimization_passes.eager_std_string_eval.**RewriteStdStringCallWalker**

Bases: *AILBlockRewriter*

**__init__**(*str_defs*, *kb*, *manager*, ***kwargs*)

**Parameters**

- **str_defs** (*dict[int, bytes]*)
- **manager** (*Manager*)

**class** angr.analyses.decompiler.optimization_passes.eager_std_string_eval.**EagerStdStringEvalPass**

Bases: *OptimizationPass*

Eagerly evaluate std::string methods for constant std::string instances.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Eagerly evaluate std::string methods for constant std::string instances'**

**DESCRIPTION = 'Eagerly evaluate std::string methods for constant std::string instances.'**

**__init__**(**args*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.engine_base

**class** angr.analyses.decompiler.optimization_passes.engine_base.**SimplifierAILState**

Bases: object

The abstract state used in SimplifierAILEngine.

**__init__**(*arch*, *variables=None*)

**copy**()

**merge**(**others*)

**store_variable**(*old*, *new*)

**Parameters**
**old** (VirtualVariable)

**get_variable**(*old*)

**Parameters**
**old** (VirtualVariable)

**remove_variable**(*old*)

**class** angr.analyses.decompiler.optimization_passes.engine_base.**SimplifierAILEngine**

Bases: *SimEngineLightAIL*[*SimplifierAILState*, *Expression*, *Statement*, Block]

Essentially implements a peephole optimization engine for AIL statements (because we do not perform memory or register loads).

### angr.analyses.decompiler.optimization_passes.expr_op_swapper

**class** angr.analyses.decompiler.optimization_passes.expr_op_swapper.**OuterWalker**

Bases: *SequenceWalker*

A sequence walker that finds nodes and invokes expression replacer to replace expressions.

**__init__**(*desc*)

**desc:** dict[*OpDescriptor*, str]

**class** angr.analyses.decompiler.optimization_passes.expr_op_swapper.**ExpressionReplacer**

Bases: *AILBlockRewriter*

Replace expressions.

**__init__**(*block_addr*, *target_expr_predicate*, *callback*)

**class** angr.analyses.decompiler.optimization_passes.expr_op_swapper.**OpDescriptor**

Bases: object

Describes a specific operator. Serializes to JSON.

**__init__**(*block_addr*, *stmt_idx*, *ins_addr*, *op*)

**Parameters**

- **block_addr** (*int*)
- **stmt_idx** (*int*)
- **ins_addr** (*int*)

- **op** (*str*)

**to_jsonable**()

**Return type**
dict[str, Any]

**to_json**()

**Return type**
str

**classmethod from_jsonable**(*d*)

**Return type**
*OpDescriptor*

**Parameters**
**d** (*dict[str, Any]*)

**classmethod from_json**(*s*)

**Return type**
*OpDescriptor*

**Parameters**
**s** (*str*)

**class** angr.analyses.decompiler.optimization_passes.expr_op_swapper.**ExprOpSwapper**

Bases: *SequenceOptimizationPass*

Swap operands (and the operator accordingly) in a BinOp expression.

**ARCHES = ['X86', 'AMD64', 'ARMEL', 'ARMHF', 'ARMCortexM', 'MIPS32', 'MIPS64']**

**PLATFORMS = ['windows', 'linux', 'cgc']**

**STAGE: *OptimizationPassStage* = 11**

**NAME = 'Swap operands of expressions as requested'**

**DESCRIPTION = 'Swap operands (and the operator accordingly) in a BinOp expression.'**

**__init__**(**args*, *binop_operators=None*, ***kwargs*)

**Parameters**
**binop_operators** (*dict[OpDescriptor, str] | None*)

### angr.analyses.decompiler.optimization_passes.flip_boolean_cmp

**class** angr.analyses.decompiler.optimization_passes.flip_boolean_cmp.**FlipBooleanWalker**

Bases: *SequenceWalker*

Walks a SequenceNode and handles every sequence. Uses the flip_size to determine when to flip the condition on large if-statement bodies.

**__init__**(*graph*, *manager*, *flip_size=9*, *last_node=None*)

**Parameters**
**manager** (*Manager*)

class angr.analyses.decompiler.optimization_passes.flip_boolean_cmp.**FlipBooleanCmp**

Bases: *SequenceOptimizationPass*

In the scenario in which a false node has no apparent successors, flip the condition on that if-stmt. This is only useful when StructuredCodeGenerator has simplify_else_scopes enabled, as this will allow the flipped if-stmt to remove the redundant else.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 11**

**NAME = 'Flip small ret booleans'**

**DESCRIPTION = 'When false node has no successors, flip condition so else scope can be simplified later'**

**__init__**(**args*, *flip_size=9*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.float128_pair_coalescer

class angr.analyses.decompiler.optimization_passes.float128_pair_coalescer.**Float128PairCoalescer**

Bases: *OptimizationPass*

Coalesce binary128 (long double) values that VEX splits across a pair of 64-bit FP registers.

s390x keeps a long double in a register pair (f0:f2, f4:f6, ...). VEX reads it with F64HLtoF128(hi, lo) and writes it back with F128HItoF64 / F128LOtoF64, so every long double turns into two 64-bit halves that are concatenated at each use. This pass gives each such pair one 128-bit variable, defined by the 128-bit operation that produced the halves or by one 16-byte load, and rewrites the uses: concatenations, stores of both halves, and spills of both halves to adjacent stack slots. 128-bit constants built from two 64-bit halves are folded too.

**ARCHES = ['S390X']**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 6**

**NAME = 'Coalesce binary128 register pairs'**

**DESCRIPTION = 'Coalesce binary128 (long double) values that VEX splits across a pair of 64-bit FP registers.\n\n s390x keeps a long double in a register pair (f0:f2, f4:f6, ...). VEX reads it with F64HLtoF128(hi, lo) and writes\n it back with F128HItoF64 / F128LOtoF64, so every long double turns into two 64-bit halves that are concatenated at\n each use. This pass gives each such pair one 128-bit variable, defined by the 128-bit operation that produced the\n halves or by one 16-byte load, and rewrites the uses:  concatenations, stores of both halves, and spills of both\n halves to adjacent stack slots. 128-bit constants built from two 64-bit halves are folded too.'**

**__init__**(*func*, **args*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.fp_negation

class angr.analyses.decompiler.optimization_passes.fp_negation.**FpNegation**

Bases: *OptimizationPass*

Rewrite floating-point sign-bit XORs (xorps/xorpd) into negation.

The lifter cannot tell an FP sign flip from an arbitrary 128-bit integer XOR with a sign-shaped constant; both produce the same AIL. This pass only rewrites when the XORed value is provably floating-point: it lives in an FP argument register of the prototype, or has FP provenance in the expression (FP conversions and operations, traced through local definitions).

It runs right before variable recovery, ahead of KnownPatternOutliner (which would otherwise outline the XOR as an opaque fneg() call), so Typehoon sees a floating-point negation instead of an integer XOR.

**ARCHES = ['X86', 'AMD64']**

**PLATFORMS = ['linux', 'windows']**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Rewrite FP sign-bit XOR to negation'**

**DESCRIPTION = 'Rewrite floating-point sign-bit XORs (``xorps``/``xorpd``) into negation.\n\n The lifter cannot tell an FP sign flip from an arbitrary 128-bit integer\n XOR with a sign-shaped constant; both produce the same AIL. This pass only\n rewrites when the XORed value is provably floating-point:  it lives in an FP\n argument register of the prototype, or has FP provenance in the expression\n (FP conversions and operations, traced through local definitions).\n\n It runs right before variable recovery, ahead of KnownPatternOutliner (which\n would otherwise outline the XOR as an opaque ``fneg()`` call), so Typehoon\n sees a floating-point negation instead of an integer XOR.'**

**__init__**(*func*, **args*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.inlined_memcpy_simplifier

class angr.analyses.decompiler.optimization_passes.inlined_memcpy_simplifier.**InlinedMemcpySimplifier**

Bases: *OptimizationPass*

Simplifies inlined data copying logic into calls to memcpy.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 3**

**NAME = 'Simplify inlined memcpy'**

**DESCRIPTION = 'Simplify inlined memcpy patterns into memcpy calls'**

**__init__**(**args*, ***kwargs*)

class angr.analyses.decompiler.optimization_passes.inlined_memcpy_simplifier.**InlinedMemcpySimplifierLate**

Bases: *InlinedMemcpySimplifier*

Same as InlinedMemcpySimplifier but runs after SSA level 1 transformation.

**STAGE**: *OptimizationPassStage* = 4

**NAME** = 'Simplify inlined memcpy (late)'

### angr.analyses.decompiler.optimization_passes.inlined_memset_simplifier

**class** angr.analyses.decompiler.optimization_passes.inlined_memset_simplifier.**ConstAssignmentInfo**

Bases: object

Holds information about a constant assignment.

**__init__**(*kind*, *base*, *offset*, *value*, *bits*, *count=1*)

**Parameters**

- **kind** (*Literal['stack', 'heap', 'global']*)
- **base** (*Any*)
- **offset** (*int*)
- **value** (*int*)
- **bits** (*int*)
- **count** (*int*)

**kind**: Literal['stack', 'heap', 'global']

**base**

**offset**

**value**

**bits**

**count**

**class** angr.analyses.decompiler.optimization_passes.inlined_memset_simplifier.**InlinedMemsetSimplifier**

Bases: *OptimizationPass*

Simplifies inlined memory setting logic into calls to memset.

**ARCHES** = None

**PLATFORMS** = None

**STAGE**: *OptimizationPassStage* = 3

**NAME** = 'Simplify inlined memset'

**DESCRIPTION** = 'Simplify inlined memset patterns into memset calls'

**MIN_ASSIGNMENTS** = 2

**__init__**(**args*, ***kwargs*)

**class** angr.analyses.decompiler.optimization_passes.inlined_memset_simplifier.**InlinedMemsetSimplifierLate**

Bases: *InlinedMemsetSimplifier*

Same as InlinedMemsetSimplifier but runs after SSA level 1 transformation.

**STAGE: *OptimizationPassStage* = 4**

**NAME = 'Simplify inlined memset (late)'**

### angr.analyses.decompiler.optimization_passes.inlined_strcpy_simplifier

**class** angr.analyses.decompiler.optimization_passes.inlined_strcpy_simplifier.**InlinedStrcpySimplifier**

Bases: *InlinedStringCopySimplifierBase*

Simplifies inlined string copying logic into calls to strcpy/strncpy, and consolidates multiple consecutive inlined strcpy calls.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 3**

**NAME = 'Simplify inlined strcpy'**

**DESCRIPTION = 'Simplify inlined strcpy patterns and consolidate multiple inlined strcpy calls'**

**__init__**(**args*, ***kwargs*)

**static is_integer_likely_a_string**(*v*, *size*, *endness*, *min_length=4*)

Check if an integer of *size* bytes stored with *endness* holds a string, optionally followed by zero bytes. On success, return all *size* bytes in memory order, including the terminator and padding.

**is_inlined_strcpy**(*stmt*)

**class** angr.analyses.decompiler.optimization_passes.inlined_strcpy_simplifier.**InlinedStrcpySimplifierLate**

Bases: *InlinedStrcpySimplifier*

Same as InlinedStrcpySimplifier but runs after SSA level 1 transformation.

**STAGE: *OptimizationPassStage* = 4**

**NAME = 'Simplify inlined strcpy (late)'**

### angr.analyses.decompiler.optimization_passes.inlined_string_transformation_simplifier

**class** angr.analyses.decompiler.optimization_passes.inlined_string_transformation_simplifier.**FasterMemory**

Bases: *SimpleInterfaceMixin*, *DefaultFillerMixin*, *UltraPagesMixin*, *PagedMemoryMixin*

A fast memory model used in InlinedStringTransformationState.

**class** angr.analyses.decompiler.optimization_passes.inlined_string_transformation_simplifier.**StackAccess**

Bases: NamedTuple

A byte-sized stack access recorded by InlinedStringTransformationAILEngine. For stores, deps holds the stack addresses that the stored value was computed from.

**kind:** str

Alias for field number 0

**codeloc:** *CodeLocation*

Alias for field number 1

**value:** BV

Alias for field number 2

**deps:** frozenset[int]

Alias for field number 3

**static __new__**(*_cls*, *kind*, *codeloc*, *value*, *deps=frozenset({})*)

Create new instance of StackAccess(kind, codeloc, value, deps)

**Parameters**

- **kind** (*str*)
- **codeloc** (CodeLocation)
- **value** (*claripy.ast.BV*)
- **deps** (*frozenset[int]*)

**class** angr.analyses.decompiler.optimization_passes.inlined_string_transformation_simplifier.**InlinedStringTransformationState**

Bases: object

The abstract state used in InlinedStringTransformationAILEngine.

**__init__**(*project*)

**stack_pointer_vvars:** set[int]

**vvar_deps:** dict[int, frozenset[int]]

**erased_bytes:** set[int]

**reg_store**(*reg*, *value*)

**Return type**
None

**Parameters**

- **reg** (Register)
- **value** (*BV*)

**reg_load**(*reg*)

**Return type**
BV | None

**Parameters**
**reg** (Register)

**mem_store**(*addr*, *value*, *endness*)

**Return type**
None

**Parameters**

- **addr** (*int*)
- **value** (*Bits*)
- **endness** (*str*)

**mem_erase**(*addr*, *size*)

**Return type**
None

**Parameters**

- **addr** (*int*)
- **size** (*int*)

**mem_load**(*addr*, *size*, *endness*)

**Return type**
BV | None

**Parameters**

- **addr** (*int*)
- **size** (*int*)

**vvar_store**(*vvar*, *value*, *is_stack_pointer*)

**Return type**
None

**Parameters**

- **vvar** (VirtualVariable)
- **value** (*Bits | None*)
- **is_stack_pointer** (*bool*)

**vvar_load**(*vvar*)

**Return type**
BV | None

**Parameters**
**vvar** (VirtualVariable)

**class** angr.analyses.decompiler.optimization_passes.inlined_string_transformation_simplifier.**InlinedStringTransformationAILEngine**

Bases: *SimEngineNostmtAIL*[*InlinedStringTransformationState*, BV | None, None, None]

A simple AIL execution engine

__init__(*project*, *nodes*, *start*, *end*, *step_limit*)

**Parameters**

- **nodes** (*dict[int, Any]*)
- **start** (*int*)
- **end** (*int*)
- **step_limit** (*int*)

**nodes:** dict[int, Any]

**start:** int

**end:** int

**step_limit:** int

**stack_accesses:** defaultdict[int, list[*StackAccess*]]

**effects:** defaultdict[int, set[str]]

**finished:** bool

class angr.analyses.decompiler.optimization_passes.inlined_string_transformation_simplifier.**InlineStringTransformationDescriptor**

Bases: object

Describes an instance of inline string transformation.

__init__(*store_block*, *loop_body*, *stack_accesses*, *beginning_stack_offset*, *removable_stmt_indices*, *live_out_values*)

**Parameters**

- **stack_accesses** (*list[list[StackAccess]]*)
- **beginning_stack_offset** (*int*)
- **removable_stmt_indices** (*set[int]*)
- **live_out_values** (*list[tuple[VirtualVariable, int, bool]]*)

class angr.analyses.decompiler.optimization_passes.inlined_string_transformation_simplifier.**InlinedStringTransformationSimplifier**

Bases: *OptimizationPass*

Simplifies inlined string transformation routines.

**ARCHES = None**

**PLATFORMS = None**

**STAGE:** *OptimizationPassStage* **= 3**

**NAME = 'Simplify string transformations'**

**DESCRIPTION = 'Simplify string transformations that are commonly used in obfuscated functions.'**

__init__(**args*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.inlined_string_utils

**class** angr.analyses.decompiler.optimization_passes.inlined_string_utils.**MemoryAccessFinder**

Bases: *AILBlockViewer*

Determines if a statement may read memory, reference the stack, or have side effects.

**__init__**()

**class** angr.analyses.decompiler.optimization_passes.inlined_string_utils.**VVarValueUseCounter**

Bases: *AILBlockViewer*

Counts value uses of virtual variables. Taking the address of a virtual variable is not a value use.

**__init__**()

**counts:** defaultdict[int, int]

**class** angr.analyses.decompiler.optimization_passes.inlined_string_utils.**InlinedStringCopySimplifierBase**

Bases: *OptimizationPass*

Helpers shared by the passes that fold constant writes into inlined string copy calls.

**__init__**(**args*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.inlined_strlen_simplifier

**class** angr.analyses.decompiler.optimization_passes.inlined_strlen_simplifier.**InlinedStrlenSimplifier**

Bases: *OptimizationPass*

Abstracts inlined strlen functions into strlen() calls.

**ARCHES = None**

**PLATFORMS = None**

**STAGE:** *OptimizationPassStage* **= 6**

**NAME = 'Identify and simplify inlined strlen() functions'**

**DESCRIPTION = 'Identify and simplify inlined strlen() functions'**

**__init__**(**args*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.inlined_wcscpy_simplifier

**class** angr.analyses.decompiler.optimization_passes.inlined_wcscpy_simplifier.**InlinedWcscpySimplifier**

Bases: *InlinedStringCopySimplifierBase*

Simplifies inlined wide string copying logic into calls to wcsncpy, and consolidates multiple consecutive inlined wcsncpy calls.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 3**

**NAME = 'Simplify inlined wcscpy'**

**DESCRIPTION = 'Simplify inlined wcscpy patterns and consolidate multiple inlined wcsncpy calls'**

**__init__**(**args*, ***kwargs*)

**static even_offsets_are_zero**(*lst*)

**static odd_offsets_are_zero**(*lst*)

**static is_integer_likely_a_wide_string**(*v*, *size*, *endness*, *min_length=4*, *char_endness=None*)

Check if an integer of *size* bytes stored with *endness* holds a wide string. *char_endness* is the byte order of each wide character (both orders are accepted if it is None). On success, return all *size* bytes in memory order, including any trailing terminator.

**is_inlined_wcscpy**(*stmt*)

**is_inlined_wcsncpy**(*stmt*)

**class** angr.analyses.decompiler.optimization_passes.inlined_wcscpy_simplifier.**InlinedWcscpySimplifierLate**

Bases: *InlinedWcscpySimplifier*

Same as InlinedWcscpySimplifier but runs after SSA level 1 transformation.

**STAGE: *OptimizationPassStage* = 4**

**NAME = 'Simplify inlined wcscpy (late)'**

### angr.analyses.decompiler.optimization_passes.insert_extract_reverter

Function-level optimization pass that collapses Insert/Extract round-trips.

On i386 cdecl at O0, double parameters are decomposed into 4-byte halves and reassembled via Insert/Extract chains that may span multiple blocks:

```
Block A:
    vvar_56 = Extract(a1, 32bits@0)
    vvar_57 = Extract(a1, 32bits@4)

Block B:
    vvar_61 = Insert(base, 0x4, vvar_57)
    vvar_62 = Insert(vvar_61, 0x0, vvar_56)
    call(vvar_62)
```

This pass resolves VVar references to their definitions across blocks and replaces the Insert chain with a direct reference to the source variable:

```
Block B:
    call(a1)
```

When the two Inserts overwrite the whole base but their values are not halves of one source (MSVC spilling two dword arguments into a qword slot for `fild qword`), the pair becomes `hi Concat lo` (except in Go binaries).

The Extract definitions (and any copies between them and the Inserts, or the overwritten base) are dropped once the collapse leaves them without uses. They are O0 spills of the parameter halves into stack locals; the generic dead-assignment removal keeps unused stack variables, so they would otherwise survive as `v0 = *((unsigned int *)&a0)`.

**class** angr.analyses.decompiler.optimization_passes.insert_extract_reverter.**InsertExtractReverter**

Bases: *OptimizationPass*

Collapse cross-block Insert(Extract()) round-trips into direct variable references.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 5**

**NAME = 'Collapse Insert/Extract round-trips'**

**DESCRIPTION = 'Collapse cross-block Insert(Extract()) round-trips into direct variable references.'**

**__init__**(*func*, *manager=None*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.ireg_replacer

**class** angr.analyses.decompiler.optimization_passes.ireg_replacer.**IRegReplacerEngine**

Bases: *SimplifierAILEngine*

**__init__**(*project*, *ail_manager=None*)

**class** angr.analyses.decompiler.optimization_passes.ireg_replacer.**IRegReplacer**

Bases: *OptimizationPass*

Replaces IRegister expressions (from GetI/PutI) with concrete Register expressions when the index has been resolved to a constant.

**ARCHES = ['X86', 'AMD64', 'ARMCortexM', 'ARMHF', 'ARMEL']**

**PLATFORMS = ['linux', 'windows']**

**STAGE: *OptimizationPassStage* = 6**

**NAME = 'Resolve IRegister to Register'**

**DESCRIPTION = 'Replaces IRegister expressions (from GetI/PutI) with concrete Register\n expressions when the index has been resolved to a constant.'**

**__init__**(*func*, **args*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.ite_expr_converter

**exception** angr.analyses.decompiler.optimization_passes.ite_expr_converter.**NodeFoundNotification**

Bases: Exception

A notification that the target node has been found.

class angr.analyses.decompiler.optimization_passes.ite_expr_converter.**BlockLocator**

Bases: *RegionWalker*

Recursively locate block in a RegionOverlay instance.

It might be reasonable to move this class into its own file.

**__init__**(*block*)

**walk_node**(*region*, *node*)

class angr.analyses.decompiler.optimization_passes.ite_expr_converter.**ExpressionReplacer**

Bases: *AILBlockRewriter*

Replace expressions.

**__init__**(*block_addr*, *target_expr*, *callback*)

class angr.analyses.decompiler.optimization_passes.ite_expr_converter.**ITEExprConverter**

Bases: *OptimizationPass*

Transform specific expressions into If-Then-Else expressions, or tertiary expressions in C when given a single-use expression address. Requires outside analysis to provide the target expressions.

**ARCHES = ['X86', 'AMD64', 'ARMEL', 'ARMHF', 'ARMCortexM', 'MIPS32', 'MIPS64']**

**PLATFORMS = ['windows', 'linux', 'cgc']**

**STAGE: *OptimizationPassStage* = 10**

**NAME = 'Transform single-use expressions that were assigned to in different If-Else branches into ternary expressions'**

**DESCRIPTION = 'Transform specific expressions into If-Then-Else expressions, or tertiary expressions in C when\n given a single-use expression address. Requires outside analysis to provide the target expressions.'**

**__init__**(**args*, *ite_exprs=None*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.ite_region_converter

class angr.analyses.decompiler.optimization_passes.ite_region_converter.**ITERegionConverter**

Bases: *OptimizationPass*

Transform regions of the form *if (c) {x = a} else {x = b}* into $x = c\ ?\ a : b$.

**ARCHES = ['X86', 'AMD64', 'ARMEL', 'ARMHF', 'ARMCortexM', 'MIPS32', 'MIPS64']**

**PLATFORMS = ['windows', 'linux', 'cgc']**

**STAGE: *OptimizationPassStage* = 6**

**NAME = 'Transform ITE-assignment regions into ternary expression assignments'**

**DESCRIPTION = 'Transform regions of the form `if (c) {x = a} else {x = b}` into `x = c ? a :  b`.'**

**__init__**(**args*, *max_updates=10*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.ite_simplifier

**class** angr.analyses.decompiler.optimization_passes.ite_simplifier.**ITESimplifierAILEngine**

Bases: *SimplifierAILEngine*

**class** angr.analyses.decompiler.optimization_passes.ite_simplifier.**ITESimplifier**

Bases: *OptimizationPass*

Simplify ITE expressions with constant condition.

**ARCHES = ['X86', 'AMD64', 'ARMCortexM', 'ARMHF', 'ARMEL']**

**PLATFORMS = ['linux', 'windows']**

**STAGE: *OptimizationPassStage* = 6**

**NAME = 'Simplify optimized ite forms'**

**DESCRIPTION = 'Simplify ITE expressions with constant condition.'**

**__init__**(*func*, **args*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.known_pattern_outliner

**class**
angr.analyses.decompiler.optimization_passes.known_pattern_outliner.**KnownPatternOutliner**

Bases: *OptimizationPass*

Automatically finds occurrences of KnownPatterns (inlined library idioms such as std::string::length() or std::vector<int>::size(); see angr.analyses.decompiler.known_patterns) in the AIL graph and outlines them into calls via the KnownPatternFinder analysis.

Runs right before variable recovery so that the synthesized calls' argument types flow into Typehoon within the same decompilation run.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Outline known code patterns into calls'**

**DESCRIPTION = "Automatically finds occurrences of KnownPatterns (inlined library idioms\n such as std::string::length() or std::vector<int>::size(); see\n angr.analyses.decompiler.known_patterns) in the AIL graph and outlines them\n into calls via the KnownPatternFinder analysis.\n\n Runs right before variable recovery so that the synthesized calls' argument\n types flow into Typehoon within the same decompilation run."**

**MAX_ROUNDS = 8**

**__init__**(*func*, *manager*, *known_patterns=None*, *recognize_known_patterns=True*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.lowered_switch_simplifier

**class** angr.analyses.decompiler.optimization_passes.lowered_switch_simplifier.**Case**

Bases: object

Describes a case in a switch-case construct.

**__init__**(*original_node*, *node_type*, *variable_hash*, *expr*, *value*, *target*, *target_idx*, *next_addr*)

**Parameters**

- **node_type** (*str | None*)
- **value** (*int | str*)
- **target** (*int*)
- **target_idx** (*int*)

**original_node**

**node_type**

**variable_hash**

**expr**

**value**

**target**

**target_idx**

**next_addr**

**class** angr.analyses.decompiler.optimization_passes.lowered_switch_simplifier.**StableVarExprHasher**

Bases: *AILBlockViewer*

Obtain a stable hash of an AIL expression with respect to all variables and all operations applied on variables.

**__init__**(*expr*, *variable_map*)

**Parameters**

**expr** (Expression)

**class** angr.analyses.decompiler.optimization_passes.lowered_switch_simplifier.**LoweredSwitchSimplifier**

Bases: *StructuringOptimizationPass*

This optimization recognizes and reverts switch cases that have been lowered and possibly split into multiple if-else statements. This optimization, discussed in the USENIX 2024 paper SAILR, aims to undo the compiler optimization known as "Switch Lowering", present in both GCC and Clang. An in-depth discussion of this optimization can be found in the paper or in our documentation of the optimization: https://github.com/mahaloz/sailr-eval/issues/14#issue-2232616411

Note, this optimization does not occur in MSVC, which uses a different optimization strategy for switch cases. As a hack for now, we only run this deoptimization on Linux binaries.

**PLATFORMS = ['linux']**

**NAME = 'Convert lowered switch-cases (if-else) to switch-cases'**

DESCRIPTION = 'Convert lowered switch-cases (if-else) to switch-cases. Only works when the Phoenix structuring algorithm is in use.'

__init__(**args*, *min_distinct_cases=2*, ***kwargs*)

static restore_graph(*node*, *last_stmt*, *graph*, *full_graph*)

**Parameters**

- **last_stmt** (IncompleteSwitchCaseHeadStatement)
- **graph** (*DiGraph*)
- **full_graph** (*DiGraph*)

static cases_issubset(*cases_0*, *cases_1*)

Test if cases_0 is a subset of cases_1.

**Return type**
bool

**Parameters**

- **cases_0** (*list[Case]*)
- **cases_1** (*list[Case]*)

### angr.analyses.decompiler.optimization_passes.mips_gp_setting_simplifier

class angr.analyses.decompiler.optimization_passes.mips_gp_setting_simplifier.MipsGpSettingSimplifier

Bases: *OptimizationPass*

Removes $gp-setting statements at the beginning of MIPS functions.

ARCHES = ['MIPS32', 'MIPS64']

PLATFORMS = ['linux']

STAGE: *OptimizationPassStage* = 6

NAME = 'Remove MIPS $gp-setting statements'

DESCRIPTION = 'Removes $gp-setting statements at the beginning of MIPS functions.'

__init__(**args*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.mod_simplifier

class angr.analyses.decompiler.optimization_passes.mod_simplifier.ModSimplifierAILEngine

Bases: *SimplifierAILEngine*

class angr.analyses.decompiler.optimization_passes.mod_simplifier.ModSimplifier

Bases: *OptimizationPass*

Simplifies optimized forms of modulo computation back to “mod”.

ARCHES = ['X86', 'AMD64', 'ARMCortexM', 'ARMHF', 'ARMEL']

PLATFORMS = ['linux', 'windows']

**STAGE:** *OptimizationPassStage* **= 6**

**NAME = 'Simplify optimized mod forms'**

**DESCRIPTION = 'Simplifies optimized forms of modulo computation back to "mod".'**

**__init__**(**args*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.nan_guard_remover

**class** angr.analyses.decompiler.optimization_passes.nan_guard_remover.**NaNGuardRemover**

Bases: *OptimizationPass*

Removes a NaN test that every predecessor has already ruled out. x86 float branches test the parity flag after the comparison, e.g., `if (a == b) { if (isunordered(a, b)) goto X; ... } else goto X`: the second jump is never taken. Left alone, return duplication splits the two jumps to X into an extra `else if` branch.

**ARCHES = None**

**PLATFORMS = None**

**STAGE:** *OptimizationPassStage* **= 6**

**NAME = 'Remove NaN tests that dominating float comparisons rule out'**

**DESCRIPTION = 'Removes a NaN test that every predecessor has already ruled out. x86 float branches test the parity flag after\n the comparison, e.g., ``if (a == b) { if (isunordered(a, b)) goto X; ... } else goto X``:  the second jump is\n never taken. Left alone, return duplication splits the two jumps to X into an extra ``else if`` branch.'**

**__init__**(**args*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.optimization_pass

**class** angr.analyses.decompiler.optimization_passes.optimization_pass.**BlockCache**

Bases: tuple

BlockCache(prop,)

**static __new__**(*_cls*, *prop*)

Create new instance of BlockCache(prop,)

**prop**

Alias for field number 0

**exception**
angr.analyses.decompiler.optimization_passes.optimization_pass.**MultipleBlocksException**

Bases: Exception

An exception that is raised in _get_block() where multiple blocks satisfy the criteria but only one block was requested.

**class**
angr.analyses.decompiler.optimization_passes.optimization_pass.**OptimizationPassStage**

Bases: Enum

Enums about optimization pass stages.

Note that the region identification pass (RegionIdentifier) may modify existing AIL blocks *without updating the topology of the original AIL graph*. For example, loop successor refinement may modify create a new AIL block with an artificial address, and alter existing jump targets of jump statements and conditional jump statements to point to this new block. However, loop successor refinement does not update the topology of the original AIL graph, which means this new AIL block does not exist in the original AIL graph. As a result, until this behavior of RegionIdentifier changes in the future, DURING_REGION_IDENTIFICATION optimization passes should not modify existing jump targets.

**AFTER_AIL_GRAPH_CREATION = 0**

**BEFORE_SSA_LEVEL0_TRANSFORMATION = 1**

**AFTER_SINGLE_BLOCK_SIMPLIFICATION = 2**

**BEFORE_SSA_LEVEL1_TRANSFORMATION = 3**

**AFTER_SSA_LEVEL1_TRANSFORMATION = 4**

**AFTER_MAKING_CALLSITES = 5**

**AFTER_GLOBAL_SIMPLIFICATION = 6**

**BEFORE_VARIABLE_RECOVERY = 7**

**AFTER_VARIABLE_RECOVERY = 8**

**BEFORE_REGION_IDENTIFICATION = 9**

**DURING_REGION_IDENTIFICATION = 10**

**AFTER_STRUCTURING = 11**

**class** angr.analyses.decompiler.optimization_passes.optimization_pass.**BaseOptimizationPass**

Bases: object

The base class for any optimization pass.

**ARCHES = []**

**PLATFORMS = []**

**STAGE:** *OptimizationPassStage*

**STRUCTURING:** list[str] | None = **None**

**NAME = 'N/A'**

**DESCRIPTION = 'N/A'**

**__init__**(*func*, *manager*)

**Parameters**
**manager** (*Manager*)

**property project:** *Project*

**property kb**

**analyze**()

class angr.analyses.decompiler.optimization_passes.optimization_pass.**OptimizationPass**

Bases: *BaseOptimizationPass*

The base class for any function-level graph optimization pass.

**__init__**(*func*, *manager*, *, *graph*, *blocks_by_addr=None*, *blocks_by_addr_and_idx=None*, *kb=None*, *region_identifier=None*, *reaching_definitions=None*, *vvar_id_start=0*, *entry_node_addr=None*, *scratch=None*, *force_loop_single_exit=True*, *refine_loops_with_single_successor=False*, *expose_loop_head_backedges=False*, *force_single_loop_entry=False*, *fold_expressions=True*, *avoid_vvar_ids=None*, *arg_vvars=None*, *peephole_optimizations=None*, *stack_pointer_tracker=None*, *notes=None*, **kwargs*)

**Parameters**

- **vvar_id_start** (*int*)
- **scratch** (*dict[str, Any] | None*)
- **force_loop_single_exit** (*bool*)
- **refine_loops_with_single_successor** (*bool*)
- **expose_loop_head_backedges** (*bool*)
- **force_single_loop_entry** (*bool*)
- **fold_expressions** (*bool*)
- **avoid_vvar_ids** (*set[int] | None*)
- **arg_vvars** (*dict[int, tuple[ailment.Expr.VirtualVariable, SimVariable]] | None*)
- **notes** (*dict | None*)

**entry_node_addr**: tuple[int, int]

**out_graph**: DiGraph | None

**stack_items**: dict[int, *StackItem*]

**analyze**()

**property blocks_by_addr**: dict[int, set[Block]]

**property blocks_by_addr_and_idx**: dict[tuple[int, int], Block]

**bfs_nodes**(*depth=None*, *start_node=None*)

**Return type**
Generator[Block]

**Parameters**

- **depth** (*int | None*)
- **start_node** (*Block | None*)

**new_block_addr**()

Return a block address that does not conflict with any existing blocks.

**Return type**
int

**Returns**
The block address.

**class** angr.analyses.decompiler.optimization_passes.optimization_pass.**SequenceOptimizationPass**

Bases: *BaseOptimizationPass*

The base class for any sequence node optimization pass.

**__init__**(*func*, *manager*, *seq=None*, ***kwargs*)

**class** angr.analyses.decompiler.optimization_passes.optimization_pass.**StructuringOptimizationPass**

Bases: *OptimizationPass*

The base class for any optimization pass that requires structuring. Optimization passes that inherit from this class should directly depend on structuring artifacts, such as regions and gotos. Otherwise, they should use OptimizationPass. This is the heaviest (computation time) optimization pass class.

By default this type of optimization should work: - on any architecture - on any platform - during region identification (to have iterative structuring) - only with the SAILR structuring algorithm

**ARCHES = None**

**PLATFORMS = None**

**STRUCTURING: list[str] | None = ['sailr']**

**STAGE: *OptimizationPassStage* = 10**

**__init__**(*func*, *manager*, *require_structurable_graph=True*, *prevent_new_gotos=True*, *strictly_less_gotos=False*, *recover_structure_fails=True*, *must_improve_rel_quality=True*, *max_opt_iters=1*, *simplify_ail=True*, *require_gotos=True*, *readd_labels=False*, *edges_to_remove=None*, ***kwargs*)

**Parameters**

- **require_structurable_graph** (*bool*)
- **prevent_new_gotos** (*bool*)
- **strictly_less_gotos** (*bool*)
- **recover_structure_fails** (*bool*)
- **must_improve_rel_quality** (*bool*)
- **max_opt_iters** (*int*)
- **simplify_ail** (*bool*)
- **require_gotos** (*bool*)
- **readd_labels** (*bool*)
- **edges_to_remove** (*list[tuple[tuple[int, int], tuple[int, int]]] | None*)

**analyze**()

### angr.analyses.decompiler.optimization_passes.pattern_outliner

**class** angr.analyses.decompiler.optimization_passes.pattern_outliner.**PatternOutliner**

Bases: *OptimizationPass*

Finds occurrences of the user's patterns (kb.patterns) in the AIL graph and outlines each into a call named after its pattern.

Where the KnownPatternOutliner matches library idioms exactly, this pass aligns a pattern the user selected and edited, so an occurrence may differ from it in the ways the pattern allows: a different operator of the same class, a statement it marked optional, an extra statement in between. An occurrence is outlined when it verifies structurally and reaches the pattern's similarity threshold. Runs right before variable recovery so the calls' declared types flow into Typehoon.

**ARCHES = None**

**PLATFORMS = None**

**STAGE = 7**

**NAME = "Outline the user's patterns into calls"**

**DESCRIPTION = "Finds occurrences of the user's patterns (kb.patterns) in the AIL\n graph and outlines each into a call named after its pattern.\n\n Where the KnownPatternOutliner matches library idioms exactly, this pass aligns a\n pattern the user selected and edited, so an occurrence may differ from it in the\n ways the pattern allows:  a different operator of the same class, a statement it\n marked optional, an extra statement in between. An occurrence is outlined when it\n verifies structurally and reaches the pattern's similarity threshold. Runs right\n before variable recovery so the calls' declared types flow into Typehoon."**

**MAX_ROUNDS = 32**

**MAX_AUTO_BLOCKS = 3**

with a derived frontier, reject a callee larger than this many times the region

**MIN_AUTO_RATIO = 0.5**

…or smaller than this fraction of it

**MIN_SUBRUN_RATIO = 0.5**

a single-entry sub-run of an occurrence must cover this share of its tokens to be outlined under the pattern's name

**__init__**(*func*, *manager*, ***kwargs*)

**outlined: list[tuple[str, tuple[int, int], float]]**

(pattern name, block location of the call, share of the occurrence's tokens covered) for every occurrence outlined; the share is below 1 when only a sub-run could be

**skipped: list[tuple[str, str]]**

(pattern name, reason) for every occurrence that was found but not outlined

**lossy: list[tuple[str, tuple[int, int], int]]**

(pattern name, call location, values dropped) for every occurrence outlined although the region leaves more values live than the call can return: the output there is wrong

**new_block_addr**()

A block address no block of the graph being rewritten has.

The base class allocates from a map of the blocks built once per stage, before any pass of the stage ran, so it hands out addresses an earlier pass of this stage (the KnownPatternOutliner, say) has already given its own new blocks; the outline is then rolled back as a duplicate block location.

**Return type**
int

### angr.analyses.decompiler.optimization_passes.peephole_simplifier

**class** angr.analyses.decompiler.optimization_passes.peephole_simplifier.**ExpressionSequenceWalker**

Bases: *SequenceWalker*

Walks sequences with generic expression handling.

**class** angr.analyses.decompiler.optimization_passes.peephole_simplifier.**PostStructuringPeepholeOptimizationPass**

Bases: *SequenceOptimizationPass*

Perform a post-structuring peephole optimization pass to simplify node statements and expressions.

**ARCHES = None**

**PLATFORMS = None**

**STAGE:** *OptimizationPassStage* **= 11**

**NAME = 'Post-Structuring Peephole Optimization'**

**DESCRIPTION = 'Perform a post-structuring peephole optimization pass to simplify node statements and expressions.'**

**__init__**(**args*, *peephole_optimizations=None*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.register_save_area_simplifier

**class** angr.analyses.decompiler.optimization_passes.register_save_area_simplifier.**RegisterSaveAreaSimplifier**

Bases: *OptimizationPass*

Optimizes away register spilling effects, including callee-saved registers.

This optimization runs between SSA-level0 and SSA-level1, which means registers are converted to vvars but stack accesses stay unchanged.

**ARCHES = None**

**PLATFORMS = None**

**STAGE:** *OptimizationPassStage* **= 2**

**NAME = 'Simplify register save areas'**

**DESCRIPTION = 'Optimizes away register spilling effects, including callee-saved registers.\n\n This optimization runs between SSA-level0 and SSA-level1, which means registers are converted to vvars but stack\n accesses stay unchanged.'**

__init__(*args, **kwargs)

### angr.analyses.decompiler.optimization_passes.register_save_area_simplifier_adv

class angr.analyses.decompiler.optimization_passes.register_save_area_simplifier_adv.RegisterSaveAreaSimplifierAdvanced

Bases: *OptimizationPass*

Optimizes away registers that are stored to or restored on the stack space.

This analysis is more complex than RegisterSaveAreaSimplifier because it handles: (1) Registers that are stored in the stack shadow space (sp+N) according to the Windows x64 calling convention. (2) Registers that are aliases of sp.

ARCHES = None

PLATFORMS = None

STAGE: *OptimizationPassStage* = 5

NAME = 'Simplify register save areas (advanced)'

DESCRIPTION = 'Optimizes away registers that are stored to or restored on the stack space.\n\n This analysis is more complex than RegisterSaveAreaSimplifier because it handles:\n (1) Registers that are stored in the stack shadow space (sp+N) according to the Windows x64 calling convention.\n (2) Registers that are aliases of sp.'

__init__(*args, **kwargs)

### angr.analyses.decompiler.optimization_passes.ret_addr_save_simplifier

class angr.analyses.decompiler.optimization_passes.ret_addr_save_simplifier.RetAddrSaveSimplifier

Bases: *OptimizationPass*

Removes code in function prologues and epilogues for saving and restoring return address registers (ra, lr, etc.), generally seen in non-leaf functions.

ARCHES = ['MIPS32', 'MIPS64']

PLATFORMS = ['linux']

STAGE: *OptimizationPassStage* = 6

NAME = 'Simplify return address storage'

DESCRIPTION = 'Removes code in function prologues and epilogues for saving and restoring return address registers (ra, lr, etc.),\n generally seen in non-leaf functions.'

__init__(*args, **kwargs)

### angr.analyses.decompiler.optimization_passes.ret_deduplicator

class angr.analyses.decompiler.optimization_passes.ret_deduplicator.**ReturnDeduplicator**

Bases: *OptimizationPass*

Transforms: - if (cond) { … return x; } return x;

into: - if (cond) { … } return x;

TODO: its possible that this can be expanded to all rets that are equivalent. Testing needed.

**ARCHES = ['X86', 'AMD64', 'ARMEL', 'ARMHF', 'ARMCortexM', 'MIPS32', 'MIPS64']**

**PLATFORMS = ['windows', 'linux', 'cgc']**

**STAGE: *OptimizationPassStage* = 10**

**NAME = 'Deduplicates return statements that may have been duplicated'**

**DESCRIPTION = 'Transforms:\n - if (cond) { ... return x; } return x;\n\n into:\n - if (cond) { ... } return x;\n\n TODO: its possible that this can be expanded to all rets that are equivalent. Testing needed.'**

**STRUCTURING: list[str] | None = ['sailr', 'dream']**

**__init__**(**args*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.ret_expr_rewriter

class angr.analyses.decompiler.optimization_passes.ret_expr_rewriter.**RetExprRewriter**

Bases: *OptimizationPass*

Rewrite return expressions for calls to functions returning several values via multiple registers.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 1**

**NAME = 'Rewrite return expressions for calls to functions returning several values via multiple registers'**

**FLAVOR = 'rust'**

**__init__**(*func*, *manager*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.return_duplicator_base

class angr.analyses.decompiler.optimization_passes.return_duplicator_base.**FreshVirtualVariableRewriter**

Bases: *AILBlockRewriter*

Helper class to rewrite virtual variables so that they will use fresh virtual variables.

**__init__**(*vvar_id_start*, *vvar_mapping*)

**Parameters**

- **vvar_id_start** (*int*)
- **vvar_mapping** (*dict[int, int]*)

class angr.analyses.decompiler.optimization_passes.return_duplicator_base.**ReturnDuplicatorBase**

Bases: object

The base class for implementing Return Duplication as described in the SAILR paper. This base class describes the general algorithm for duplicating return regions in a graph.

**__init__**(*func*, *manager*, ***, *vvar_id_start*, *max_calls_in_regions=2*, *minimize_copies_for_regions=True*, *ri=None*, *scratch=None*, *max_func_blocks=1500*)

**Parameters**

- **vvar_id_start** (*int*)
- **max_calls_in_regions** (*int*)
- **minimize_copies_for_regions** (*bool*)
- **ri** (*RegionIdentifier | None*)
- **scratch** (*dict[str, Any] | None*)
- **max_func_blocks** (*int*)

**next_node_idx**(*addr*, *graph*)

**Return type**
int

**Parameters**

- **addr** (*int*)
- **graph** (*DiGraph*)

**static unwrap_conv**(*expr*)

### angr.analyses.decompiler.optimization_passes.return_duplicator_high

class angr.analyses.decompiler.optimization_passes.return_duplicator_high.**ReturnDuplicatorHigh**

Bases: *OptimizationPass*, *ReturnDuplicatorBase*

This is a light-level goto-less version of the ReturnDuplicator optimization pass. It will only duplicate return-only blocks.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 6**

**NAME = 'Duplicate return-only blocks (high)'**

**DESCRIPTION = '\n This is a light-level goto-less version of the ReturnDuplicator optimization pass. It will only\n duplicate return-only blocks.\n '**

**STRUCTURING: list[str] | None = ['sailr', 'dream']**

__init__(**args*, *vvar_id_start*, *max_calls_in_regions=2*, *minimize_copies_for_regions=True*, *scratch=None*, ***kwargs*)

**Parameters**

- **vvar_id_start** (*int*)
- **max_calls_in_regions** (*int*)
- **minimize_copies_for_regions** (*bool*)
- **scratch** (*dict[str, Any] | None*)

### angr.analyses.decompiler.optimization_passes.return_duplicator_low

**class** angr.analyses.decompiler.optimization_passes.return_duplicator_low.**ReturnDuplicatorLow**

Bases: *StructuringOptimizationPass*, *ReturnDuplicatorBase*

An optimization pass that reverts a subset of Irreducible Statement Condensing (ISC) optimizations, as described in the USENIX 2024 paper SAILR. This is the heavy/goto version of the ReturnDuplicator optimization pass.

Some compilers, including GCC, Clang, and MSVC, apply various optimizations to reduce the number of statements in code. These optimizations will take equivalent statements, or a subset of them, and replace them with a single copy that is jumped to by gotos – optimizing for space and sometimes speed.

This optimization pass will revert those gotos by re-duplicating the condensed blocks. Since Return statements are the most common, we use this optimization pass to revert only gotos to return statements. Additionally, we perform some additional readability fixups, like not re-duplicating returns to shared components.

**Parameters**

- **func** – The function to optimize.
- **node_idx_start** – The index to start at when creating new nodes. This is used by Clinic to ensure that node indices are unique across multiple passes.
- **max_opt_iters** (int) – The maximum number of optimization iterations to perform.
- **max_calls_in_regions** (int) – The maximum number of calls that can be in a region. This is used to prevent duplicating too much code.
- **prevent_new_gotos** (bool) – If True, this optimization pass will prevent new gotos from being created.
- **minimize_copies_for_regions** (bool) – If True, this optimization pass will minimize the number of copies by doing only a single copy for connected in_edges that form a region.

**ARCHES = None**

**PLATFORMS = None**

**NAME = 'Duplicate returns connect with gotos (low)'**

DESCRIPTION = 'An optimization pass that reverts a subset of Irreducible Statement Condensing (ISC) optimizations, as described\nin the USENIX 2024 paper SAILR. ### angr.analyses.decompiler.optimization_passes.rewriter_utils

angr.analyses.decompiler.optimization_passes.rewriter_utils.**extract_callee**(*obj*, *kb*)

angr.analyses.decompiler.optimization_passes.rewriter_utils.**extract_str**(*project*, *str_ptr*, *str_len*)

Extract Rust string literal with given ptr and len

angr.analyses.decompiler.optimization_passes.rewriter_utils.**extract_str_from_addr**(*project*, *addr*)

**class** angr.analyses.decompiler.optimization_passes.rewriter_utils.**SideEffectStatementRewriter**

Bases: *AILBlockRewriter*

Rewrite SideEffectStatement nodes via a callback.

__init__(*callback*)

**class** angr.analyses.decompiler.optimization_passes.rewriter_utils.**CallRewriter**

Bases: *AILBlockRewriter*

Rewrite Call expressions and SideEffectStatements via a callback.

__init__(*callback*)

angr.analyses.decompiler.optimization_passes.rewriter_utils.**replace_argument_pairs**(*call*, *callback*)

**Return type**
*Call*

**Parameters**
**call** (Call)

### angr.analyses.decompiler.optimization_passes.stack_canary_simplifier

**class** angr.analyses.decompiler.optimization_passes.stack_canary_simplifier.**StackCanarySimplifier**

Bases: *OptimizationPass*

Removes stack canary checks from decompilation results.

**ARCHES = ['X86', 'AMD64']**

**PLATFORMS = ['cgc', 'linux']**

**STAGE: *OptimizationPassStage* = 6**

**NAME = 'Simplify stack canaries'**

**DESCRIPTION = 'Removes stack canary checks from decompilation results.'**

**__init__**(**args*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.static_vvar_rewriter

**class** angr.analyses.decompiler.optimization_passes.static_vvar_rewriter.**FixedBuffer**

Bases: object

A fixed-size buffer with known content.

**__init__**(*ident*, *size*, *content*)

**Parameters**
- **ident** (*str | None*)
- **size** (*int*)
- **content** (bytes)

**class** angr.analyses.decompiler.optimization_passes.static_vvar_rewriter.**FixedBufferPtr**

Bases: object

A pointer to a fixed-size buffer.

**__init__**(*buffer_ident*, *offset=0*)

**Parameters**
- **buffer_ident** (*str*)
- **offset** (*int*)

class angr.analyses.decompiler.optimization_passes.static_vvar_rewriter.**Offset**

Bases: object

Describes an offset value.

**__init__**(*value*, *bits*)

**Parameters**

- **value** (*int*)
- **bits** (*int*)

class angr.analyses.decompiler.optimization_passes.static_vvar_rewriter.**VVarRewritingVisitor**

Bases: *AILBlockRewriter*

The visitor that rewrites vvars and their reads.

**__init__**(*static_buffers*, *static_vvars*, *kb*, *manager*)

**Parameters**

- **static_buffers** (*dict[str, FixedBuffer]*)
- **static_vvars** (*dict[int, FixedBufferPtr | Const]*)
- **manager** (*Manager*)

class angr.analyses.decompiler.optimization_passes.static_vvar_rewriter.**VVarAliasVisitor**

Bases: *AILBlockViewer*

The visitor that discovers const assignments and aliases of existing static vvars.

**__init__**(*static_buffers*, *static_vvars*, *kb*, *manager*)

**Parameters**

- **static_buffers** (*dict[str, FixedBuffer]*)
- **static_vvars** (*dict[int, FixedBufferPtr | Const]*)
- **manager** (*Manager*)

class angr.analyses.decompiler.optimization_passes.static_vvar_rewriter.**StaticVVarRewriter**

Bases: *OptimizationPass*

Rewrite user-specified vvars as static values or fix-sized buffers. Also rewrites reads from pointers derived off of such vvars.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 7**

**NAME = 'Static virtual variable rewriter'**

**DESCRIPTION = 'Rewrite user-specified vvars as static values or fix-sized buffers. Also rewrites reads from pointers derived off\n of such vvars.'**

__init__(*args*, *static_buffers=None*, *static_vvars=None*, ***kwargs*)

**Parameters**

- **static_buffers** (*dict[str, FixedBuffer] | None*)
- **static_vvars** (*dict[int, FixedBufferPtr | Const] | None*)

### angr.analyses.decompiler.optimization_passes.switch_default_case_duplicator

**class** angr.analyses.decompiler.optimization_passes.switch_default_case_duplicator.**SwitchDefaultCaseDuplicator**

Bases: *OptimizationPass*

For each switch-case construct (identified by jump tables), duplicate the default-case node when we detect situations where the default-case node is seemingly reused by edges outside the switch-case construct. This code reuse is usually caused by compiler code deduplication.

Ideally this pass should be implemented as an ISC optimization reversion.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 0**

**NAME = 'Duplicate default-case nodes to undo default-case node reuse caused by compiler code deduplication'**

**DESCRIPTION = 'For each switch-case construct (identified by jump tables), duplicate the default-case node when we detect\n situations where the default-case node is seemingly reused by edges outside the switch-case construct. This code\n reuse is usually caused by compiler code deduplication.\n\n Ideally this pass should be implemented as an ISC optimization reversion.'**

__init__(**args*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.switch_reused_entry_rewriter

**class** angr.analyses.decompiler.optimization_passes.switch_reused_entry_rewriter.**SwitchReusedEntryRewriter**

Bases: *OptimizationPass*

For each switch-case construct (identified by jump tables), rewrite the entry into a goto block when we detect situations where an entry node is reused by edges in switch-case constructs that are not the current one. This code reuse is usually caused by compiler code deduplication.

The *max_entry_reuse_count* parameter controls the maximum number of times an entry can be reused in different jump tables in the same function; exceeding this threshold probably indicates that the jump table recovery is incorrect and thus creating jump tables with too many duplicate entries.

The *max_reused_entries* parameter controls the maximum number of reused entries that can be found in a function before aborting this optimization.

**ARCHES = None**

**PLATFORMS = None**

**STAGE: *OptimizationPassStage* = 0**

NAME = 'Rewrite switch-case entry nodes with multiple predecessors into goto statements.'

DESCRIPTION = 'For each switch-case construct (identified by jump tables), rewrite the entry into a goto block when we detect\n situations where an entry node is reused by edges in switch-case constructs that are not the current one. This code\n reuse is usually caused by compiler code deduplication.\n\n The `max_entry_reuse_count` parameter controls the maximum number of times an entry can be reused in different jump\n tables in the same function; exceeding this threshold probably indicates that the jump table recovery is incorrect\n and thus creating jump tables with too many duplicate entries.\n\n The `max_reused_entries` parameter controls the maximum number of reused entries that can be found in a function\n before aborting this optimization.'

__init__(**args*, *max_entry_reuse_count=10*, *max_reused_entries=20*, ***kwargs*)

**Parameters**

- **max_entry_reuse_count** (*int*)
- **max_reused_entries** (*int*)

### angr.analyses.decompiler.optimization_passes.tag_slicer

class angr.analyses.decompiler.optimization_passes.tag_slicer.**TagSlicer**

Bases: *OptimizationPass*

Removes unmarked statements from the graph.

ARCHES = None

PLATFORMS = None

STAGE: *OptimizationPassStage* = 8

NAME = 'Remove unmarked statements from the graph.'

DESCRIPTION = 'Removes unmarked statements from the graph.'

__init__(**args*, ***kwargs*)

### angr.analyses.decompiler.optimization_passes.win_stack_canary_simplifier

class angr.analyses.decompiler.optimization_passes.win_stack_canary_simplifier.**WinStackCanarySimplifier**

Bases: *OptimizationPass*

Removes stack canary checks from decompilation results for Windows PE files.

we need to run this pass before performing any full-function simplification. Otherwise the effects of _security_cookie will be propagated.

ARCHES = ['X86', 'AMD64']

PLATFORMS = ['windows']

STAGE: *OptimizationPassStage* = 2

NAME = 'Simplify stack canaries in Windows PE files'

DESCRIPTION = 'Removes stack canary checks from decompilation results for Windows PE files.\n\n we need to run this pass before performing any full-function simplification. Otherwise the effects of\n _security_cookie will be propagated.'

__init__(*args, **kwargs)

### angr.analyses.decompiler.optimization_passes.x86_gcc_getpc_simplifier

class angr.analyses.decompiler.optimization_passes.x86_gcc_getpc_simplifier.X86GccGetPcSimplifier

Bases: *OptimizationPass*

Simplifies __x86.get_pc_thunk calls.

ARCHES = ['X86']

PLATFORMS = ['linux']

STAGE: *OptimizationPassStage* = 1

NAME = 'Simplify getpc()'

DESCRIPTION = 'Simplifies __x86.get_pc_thunk calls.'

__init__(*args, **kwargs)

### angr.analyses.decompiler.optimization_passes.x87_fprem_loop

class angr.analyses.decompiler.optimization_passes.x87_fprem_loop.X87FpremLoopSimplifier

Bases: *OptimizationPass*

Collapse the x87 remainder loop `L: fprem[1]; fnstsw ax; sahf; jp L` into a single fmod() / remainder().

fprem and fprem1 only reduce the exponent difference by up to 63 per step and set C2 while the remainder is partial; the loop repeats them until C2 is clear, which yields the complete IEEE remainder. The self-loop block is turned into a straight-line block: PRem/PRem1 already stand for the complete operation, and C2 is clear when the loop exits. The status intrinsic stays only where something after the loop reads its quotient bits.

ARCHES = ['X86', 'AMD64']

PLATFORMS = None

STAGE: *OptimizationPassStage* = 6

NAME = 'Collapse x87 fprem/fprem1 loops'

DESCRIPTION = 'Collapse the x87 remainder loop ``L: fprem[1]; fnstsw ax; sahf; jp L`` into a single fmod() / remainder().\n\n fprem and fprem1 only reduce the exponent difference by up to 63 per step and set C2 while the remainder is\n partial; the loop repeats them until C2 is clear, which yields the complete IEEE remainder. The self-loop block is\n turned into a straight-line block: PRem/PRem1 already stand for the complete operation, and C2 is clear when the\n loop exits. The status intrinsic stays only where something after the loop reads its quotient bits.'

__init__(*args, **kwargs)

### angr.analyses.decompiler.pattern_match

Fuzzy repeated-code discovery for decompiled functions.

Inlined duplicated code – obfuscator decryption stubs, expanded macros, copies of an inlined helper – is almost never byte-identical: constants differ per site and the optimizer reorders and reassociates around them. Exact matching therefore finds nothing useful, which is why this package canonicalizes an AIL graph into a token stream (*tokenizer*) and runs a sparse local self-alignment over it (*align*) to recover the near-duplicate families.

Families alone cannot be merged: members that align at 90% still differ somewhere. *exact* therefore extracts the sub-ranges on which a family agrees exactly modulo constants, and *dedup* outlines those into a single shared function with the differing constants lifted into parameters.

**class** angr.analyses.decompiler.pattern_match.**AILCanonicalizer**

Bases: object

Renders AIL statements into canonical shape strings.

**__init__**(*, *max_depth=5*, *keep_vvar_category=True*, *keep_sizes=True*, *const_mode='abstract'*, *kb=None*, *block_pos=None*, *loader=None*, *skip_conversions=False*)

**Parameters**

- **max_depth** (*int*)
- **keep_vvar_category** (*bool*)
- **keep_sizes** (*bool*)
- **const_mode** (*str*)
- **kb** (KnowledgeBase | *None*)
- **block_pos** (*dict[Address, int] | None*)
- **skip_conversions** (*bool*)

**statement**(*stmt*, *cur_pos=None*)

**Return type**
str

**Parameters**

- **stmt** (Statement)
- **cur_pos** (*int | None*)

**bag**(*stmt*, *max_depth=8*)

**Return type**
Counter

**Parameters**

- **stmt** (Statement)
- **max_depth** (*int*)

**static klass_of**(*shape*)

Fold operator names in a shape string into operator classes, and variables of any category (VR, VS, ...) into V: the same idiom keeps a value in a register in one copy and on the stack in another.

**Return type**
str

**Parameters**
**shape** (*str*)

class angr.analyses.decompiler.pattern_match.**AlignParams**

Bases: object

Knobs for the whole pipeline.

**k:** int = 4

**window:** int = 0

**max_seed_multiplicity:** int = 80

**min_anchors:** int = 4

**max_gap:** int = 30

**band:** int = 16

**pad:** int = 40

**match:** float = 3.0

**klass_match:** float = 1.0

**mismatch:** float = -2.0

**gap_open:** float = -4.0

**gap_extend:** float = -1.0

**min_score:** float = 40.0

**min_identity:** float = 0.5

**min_size:** int = 8

**min_occurrences:** int = 2

**max_candidates:** int = 4000

**overlap_ratio:** float = 0.5

**allow_tandem:** bool = False

**min_votes:** int = 5

a diagonal needs this many statements of the template voting for it to be aligned, or a quarter of the template's concrete statements if that is fewer, so small templates are never pruned

**Type**
template search

**__init__**(*k=4*, *window=0*, *max_seed_multiplicity=80*, *min_anchors=4*, *max_gap=30*, *band=16*, *pad=40*, *match=3.0*, *klass_match=1.0*, *mismatch=-2.0*, *gap_open=-4.0*, *gap_extend=-1.0*, *min_score=40.0*, *min_identity=0.5*, *min_size=8*, *min_occurrences=2*, *max_candidates=4000*, *overlap_ratio=0.5*, *allow_tandem=False*, *min_votes=5*)

**Parameters**

- **k** (*int*)

- **window** (*int*)
- **max_seed_multiplicity** (*int*)
- **min_anchors** (*int*)
- **max_gap** (*int*)
- **band** (*int*)
- **pad** (*int*)
- **match** (*float*)
- **klass_match** (*float*)
- **mismatch** (*float*)

- **min_size** (*int*)
- **min_occurrences** (*int*)
- **max_candidates** (*int*)
- **overlap_ratio** (*float*)
- **allow_tandem** (*bool*)
- **min_votes** (*int*)

**Return type**
None

**class** angr.analyses.decompiler.pattern_match.**Alignment**

Bases: object

One fuzzy match between two token ranges.

**a:** *Interval*

**b:** *Interval*

**score:** float

**matched:** int

**columns:** int

**property identity:** float

**__init__**(*a*, *b*, *score*, *matched*, *columns*)

**Parameters**

- **a** (Interval)
- **b** (Interval)
- **score** (*float*)
- **matched** (*int*)

- **columns** (*int*)

**Return type**
None

class angr.analyses.decompiler.pattern_match.**Checkpoint**

Bases: object

Called from inside hot loops, as often as is convenient.

Every `freq` calls it looks at the clock, and at most once per `interval` seconds it sleeps for `sleep` seconds to let other threads take the GIL, as the CFG's low-priority mode does, and then runs `callback`. The callback may raise to abort the analysis; a UI uses that to cancel.

**__init__**(*low_priority=True*, *callback=None*, *freq=1*, *interval=0.02*, *sleep=0.001*)

**Parameters**

- **low_priority** (*bool*)
- **callback** (*Callable[[], None] | None*)
- **freq** (*int*)
- **interval** (*float*)
- **sleep** (*float*)

**low_priority**

**callback**

**freq**

**interval**

**sleep**

class angr.analyses.decompiler.pattern_match.**DedupResult**

Bases: object

What `PatternDeduplicator` did.

**graph: networkx.DiGraph[Block]**

**outlined: list[*OutlinedRegion*]**

**groups: list[*MergeGroup*]**

**skipped: list[tuple[*Interval*, str]]**

**property statements_removed: int**

Statements actually moved out of the parent.

**__init__**(*graph*, *outlined=<factory>*, *groups=<factory>*, *skipped=<factory>*)

**Parameters**

- **graph** (*networkx.DiGraph[Block]*)
- **outlined** (*list[OutlinedRegion]*)
- **groups** (*list[MergeGroup]*)
- **skipped** (*list[tuple[Interval, str]]*)

**Return type**
None

class angr.analyses.decompiler.pattern_match.**ExactCore**

Bases: object

A range on which several occurrences agree exactly on canonical shapes.

**occurrences:** list[*Interval*]

**length:** int

**property support:** int

**property savings:** int

**__init__**(*occurrences*, *length*)

**Parameters**

- **occurrences** (*list[Interval]*)
- **length** (*int*)

**Return type**
None

class angr.analyses.decompiler.pattern_match.**Fit**

Bases: IntEnum

How well a node fits a shape. Ordered so `min` combines children.

**NONE = 0**

**KLASS = 1**

**EXACT = 2**

**__new__**(*value*)

class angr.analyses.decompiler.pattern_match.**FuzzyPattern**

Bases: object

A family of near-duplicate regions, plus the sub-ranges they share exactly.

**cluster:** *PatternCluster*

**occurrences:** list[*PatternOccurrence*]

**cores:** list[*ExactCore*]

**core_occurrences:** list[list[*PatternOccurrence*]]

**property identity:** float

**property size:** int

**property savings:** float

**property sound_savings:** int

Tokens removable without changing semantics, i.e. via the exact cores.

property outlinable_occurrences: list[*PatternOccurrence*]

__init__(*cluster*, *occurrences*, *cores=<factory>*, *core_occurrences=<factory>*)

**Parameters**

- **cluster** (PatternCluster)
- **occurrences** (*list[*PatternOccurrence*]*)
- **cores** (*list[*ExactCore*]*)
- **core_occurrences** (*list[list[*PatternOccurrence*]]*)

**Return type**
None

class angr.analyses.decompiler.pattern_match.**FuzzyPatternFinder**

Bases: *Analysis*

Find fuzzy repeated code in an AIL graph.

Duplicated inlined code (obfuscator-generated decryption stubs, expanded macros, copies of an inlined helper) is rarely byte-identical: constants differ per site and optimizers reorder and reassociate. Exact matching finds nothing, so this analysis linearizes the graph into a canonical token stream and runs a sparse local self-alignment over it (see *align*).

Two tiers of result are produced. `patterns` holds the fuzzy families, which is what you want to understand a function. Each family also carries `cores`: the sub-ranges its members agree on *exactly*, which is what you can soundly merge into a single shared function.

**Parameters**

- **func** (*Function*) – The function being analyzed.
- **ail_graph** (networkx.DiGraph[Block]) – Its AIL graph, e.g. `Decompiler.ail_graph`.
- **params** (*AlignParams* | None) – Alignment knobs; see *AlignParams*.
- **disjoint** (bool) – Keep only a non-overlapping subset of families (what outlining needs). `all_patterns` always has the full list.
- **min_core_len** (int) – Shortest exact core worth reporting.
- **resolve_calls** (bool) – Render call targets by callee name, which makes calls strong anchors for the aligner.

__init__(*func*, *ail_graph*, ***, *params=None*, *disjoint=True*, *min_core_len=4*, *min_core_support=2*, *max_depth=5*, *const_mode='abstract'*, *skip_labels=True*, *skip_phis=True*, *skip_dephi=True*, *resolve_calls=True*, *entry=None*, *low_priority=False*, *checkpoint=None*, *statements='any'*)

**Parameters**

- **func** (Function)
- **ail_graph** (*networkx.DiGraph[*Block*]*)
- **params** (AlignParams | *None*)
- **disjoint** (*bool*)
- **min_core_len** (*int*)
- **min_core_support** (*int*)
- **max_depth** (*int*)

- **const_mode** (*str*)
- **skip_labels** (*bool*)
- **skip_phis** (*bool*)
- **skip_dephi** (*bool*)
- **resolve_calls** (*bool*)
- **entry** (Block | *None*)
- **low_priority** (*bool*)
- **checkpoint** (Callable[[], *None*] | *None*)
- **statements** (*str*)

**statements**

how the statements of one occurrence may follow each other; see STATEMENTS_MODES

**stream:** *TokenStream*

**all_patterns:** list[*FuzzyPattern*]

**patterns:** list[*FuzzyPattern*]

**summary**(*limit=20*)

A human-readable report of what was found.

**Return type**
str

**Parameters**
**limit** (*int*)

**class** angr.analyses.decompiler.pattern_match.**Interval**

Bases: object

A half-open token range [start, end).

**start:** int

**end:** int

**overlaps**(*other*)

**Return type**
bool

**Parameters**
**other** (Interval)

**overlap_len**(*other*)

**Return type**
int

**Parameters**
**other** (Interval)

__init__(*start*, *end*)

**Parameters**

- **start** (*int*)
- **end** (*int*)

**Return type**
None

class angr.analyses.decompiler.pattern_match.**MergeGroup**

Bases: object

Several outlined regions folded into one shared function.

**name:** str

**members:** list[*OutlinedRegion*]

**lifted_const_indices:** list[int]

**property size:** int

__init__(*name*, *members*, *lifted_const_indices=<factory>*)

**Parameters**

- **name** (*str*)
- **members** (*list[OutlinedRegion]*)
- **lifted_const_indices** (*list[int]*)

**Return type**
None

class angr.analyses.decompiler.pattern_match.**PatternCluster**

Bases: object

A group of occurrences of one fuzzy pattern.

**occurrences:** list[*Interval*]

**score:** float

**identity:** float

**alignments:** list[*Alignment*]

**property size:** int

**property savings:** float

every occurrence but one disappears.

**Type**
Tokens removed by outlining

**spans**()

**Return type**
list[*Interval*]

__init__(*occurrences*, *score*, *identity*, *alignments=<factory>*)

**Parameters**

- **occurrences** (*list[Interval]*)
- **score** (*float*)
- **identity** (*float*)
- **alignments** (*list[Alignment]*)

**Return type**
None

class angr.analyses.decompiler.pattern_match.**PatternDeduplicator**

Bases: *Analysis*

Outline fuzzy patterns out of a function and merge the provably equal ones.

**Parameters**

- **func** (*Function*) – The function being rewritten.
- **ail_graph** (networkx.DiGraph[Block]) – Its AIL graph. Not mutated; a copy is rewritten.
- **patterns** (list[*FuzzyPattern*]) – Patterns from *FuzzyPatternFinder*.
- **granularity** (str) – "core" (default, always mergeable) or "occurrence" (maximum bulk removal).
- **merge** (bool) – Fold provably identical callees into one function.
- **frontier_mode** (str) – "region" outlines exactly the discovered interval; "fallback" (default) additionally retries regions that are not single-entry by letting the Outliner derive its own frontier.
- **max_auto_blocks** (int) – Bound, as a multiple of the region's block count, on how large a derived frontier may grow.
- **min_auto_ratio** (float) – Smallest fraction of the region a derived frontier may cover before the outline is judged unrelated to the pattern and rolled back.
- **name_prefix** (str) – Prefix for synthesized function names.

__init__(*func*, *ail_graph*, *patterns*, *stream*, ***, *granularity='core'*, *merge=True*, *name_prefix='fuzzy'*, *vvar_id_start=53248*, *block_addr_start=2882338816*, *const_param_stack_base=-65536*, *min_group_size=2*, *validate=True*, *frontier_mode='fallback'*, *max_auto_blocks=3*, *min_auto_ratio=0.5*)

**Parameters**

- **func** (Function)
- **ail_graph** (*networkx.DiGraph[Block]*)
- **patterns** (*list[FuzzyPattern]*)
- **stream** (TokenStream)
- **granularity** (*str*)
- **merge** (*bool*)
- **name_prefix** (*str*)
- **vvar_id_start** (*int*)

- **block_addr_start** (*int*)
- **const_param_stack_base** (*int*)
- **min_group_size** (*int*)
- **validate** (*bool*)
- **frontier_mode** (*str*)
- **max_auto_blocks** (*int*)
- **min_auto_ratio** (*float*)

**summary**()

**Return type**
str

class angr.analyses.decompiler.pattern_match.**PatternOccurrence**

Bases: object

One occurrence of a discovered pattern, with its outlining verdict.

**interval:** *Interval*

**region:** *Region*

**property outlinable:** bool

**property block_locs:** list[tuple[int, int]]

**__init__**(*interval*, *region*)

**Parameters**
- **interval** (Interval)
- **region** (Region)

**Return type**
None

class angr.analyses.decompiler.pattern_match.**Region**

Bases: object

An interval mapped onto AIL blocks, with its outlinability verdict.

**interval:** *Interval*

**block_locs:** list[tuple[int, int]]

**src_loc:** tuple[int, int]

**frontier:** set[tuple[int, int]]

**head_split:** int = 0

**tail_split:** int = 0

**outlinable:** bool = False

**reason:** str = ''

property needs_split: bool

__init__(*interval*, *block_locs*, *src_loc*, *frontier=<factory>*, *head_split=0*, *tail_split=0*, *outlinable=False*, *reason=''*)

**Parameters**

- **interval** (Interval)
- **block_locs** (*list[tuple[int, int]]*)
- **src_loc** (*tuple[int, int]*)
- **frontier** (*set[tuple[int, int]]*)
- **head_split** (*int*)
- **tail_split** (*int*)
- **outlinable** (*bool*)
- **reason** (*str*)

**Return type**
None

class angr.analyses.decompiler.pattern_match.**TemplateColumn**

Bases: object

One leaf of the template and what it landed on.

token is the stream position, or None when the leaf was skipped. verified is None until verify() runs, then whether the node's own structural match accepted the statement.

leaf: int

token: int | None

fit: *Fit*

verified: bool | None = None

__init__(*leaf*, *token*, *fit*, *verified=None*)

**Parameters**

- **leaf** (*int*)
- **token** (*int | None*)
- **fit** (Fit)
- **verified** (*bool | None*)

**Return type**
None

class angr.analyses.decompiler.pattern_match.**TemplateMatch**

Bases: object

One occurrence of a template in a stream.

interval: *Interval*

score: float

**similarity:** float

score over the best score the required leaves could reach, clamped to 1

**identity:** float

fraction of required leaves that fit exactly

**columns:** list[TemplateColumn]

**verified:** bool | None = None

every required leaf passed its structural match

**Type**
after verify()

**captures:** dict[str, object]

the capture bindings, by name

**Type**
after verify()

**property placed_leaves:** int

**__init__**(*interval*, *score*, *similarity*, *identity*, *columns*, *verified=None*, *captures=<factory>*)

**Parameters**

- **interval** (*Interval*)
- **score** (*float*)
- **similarity** (*float*)
- **identity** (*float*)
- **columns** (*list[TemplateColumn]*)
- **verified** (*bool | None*)
- **captures** (*dict[str, object]*)

**Return type**
None

**class** angr.analyses.decompiler.pattern_match.**TokenLoc**

Bases: object

Where a token came from.

**block_addr:** int

**block_idx:** int

**stmt_idx:** int

**block_pos:** int

**ins_addr:** int | None

**property block_loc:** tuple[int, int]

__init__(*block_addr*, *block_idx*, *stmt_idx*, *block_pos*, *ins_addr*)

**Parameters**

- **block_addr** (*int*)
- **block_idx** (*int*)
- **stmt_idx** (*int*)
- **block_pos** (*int*)
- **ins_addr** (*int | None*)

**Return type**
None

class angr.analyses.decompiler.pattern_match.**TokenStream**

Bases: object

A linearized, canonicalized view of an AIL graph.

**blocks:** list[Block]

**block_span:** dict[tuple[int, int], tuple[int, int]]

**locs:** list[*TokenLoc*]

**shapes:** list[str]

**klasses:** list[str]

**bags:** list[Counter]

**shape_ids:** list[int]

**klass_ids:** list[int]

**shape_vocab:** list[str]

**klass_vocab:** list[str]

**klass_of_shape:** list[int]

**kb:** *KnowledgeBase* | None = None

the knowledge base the callee names were resolved against, for a verifier to reuse

**block_locs_in**(*start*, *end*)

Block locations touched by tokens [start, end), in linearization order.

**Return type**
list[tuple[int, int]]

**Parameters**

- **start** (*int*)
- **end** (*int*)

**covers_whole_block**(*start*, *end*, *block_loc*)

**Return type**
bool

**Parameters**

- **start** (*int*)
- **end** (*int*)
- **block_loc** (*tuple[int, int]*)

**addr_range**(*start*, *end*)

**Return type**
tuple[int | None, int | None]

**Parameters**

- **start** (*int*)
- **end** (*int*)

**__init__**(*blocks*, *block_span*, *locs*, *shapes*, *klasses*, *bags*, *shape_ids*, *klass_ids*, *shape_vocab=<factory>*, *klass_vocab=<factory>*, *klass_of_shape=<factory>*, *kb=None*)

**Parameters**

- **blocks** (*list[Block]*)
- **block_span** (*dict[Address, tuple[int, int]]*)
- **locs** (*list[TokenLoc]*)
- **shapes** (*list[str]*)
- **klasses** (*list[str]*)
- **bags** (*list[Counter]*)
- **shape_ids** (*list[int]*)
- **klass_ids** (*list[int]*)
- **shape_vocab** (*list[str]*)
- **klass_vocab** (*list[str]*)
- **klass_of_shape** (*list[int]*)
- **kb** (KnowledgeBase | *None*)

**Return type**
None

angr.analyses.decompiler.pattern_match.**discover**(*ids*, *klass_of_shape*, *params=None*, *checkpoint=None*, *segment=None*, *glue=frozenset({})*)

Full pipeline: seed -> chain -> align -> cluster. `checkpoint` is called from the alignment loops, where the time goes; see *priority.Checkpoint*. `segment` gives each token a segment number that no occurrence may cross out of, and `glue` the shape ids of unconditional jumps, which score nothing and cost nothing to skip.

**Return type**
list[*PatternCluster*]

**Parameters**

- **ids** (*list[int]*)
- **klass_of_shape** (*list[int]*)
- **params** (AlignParams | *None*)
- **checkpoint** (Callable[[], None] | *None*)

- **segment** (*list[int] | None*)
- **glue** (*frozenset[int]*)

angr.analyses.decompiler.pattern_match.**find_exact_cores**(*ids*, *occurrences*, ***, *min_len=4*, *min_support=2*, *max_cores=32*)

Greedily extract maximal exactly-shared cores from a fuzzy family.

**Return type**
list[*ExactCore*]

**Parameters**

- **ids** (*list[int]*)
- **occurrences** (*list[Interval]*)
- **min_len** (*int*)
- **min_support** (*int*)
- **max_cores** (*int*)

angr.analyses.decompiler.pattern_match.**find_template_occurrences**(*pattern*, *graph*, *entry*, ***, *kb=None*, *params=None*, *ctx=None*, *checkpoint=None*)

Tokenize `graph`, search it for `pattern`, and verify every hit.

**Return type**
tuple[*TokenStream*, list[TemplateMatch]]

**Parameters**

- **pattern** (KnownPattern | dsl.PatternNode)
- **graph** (*networkx.DiGraph[Block]*)
- **entry** (Block)
- **kb** (KnowledgeBase | *None*)
- **params** (AlignParams | *None*)
- **ctx** (MatchCtx | *None*)
- **checkpoint** (*Callable[[], None] | None*)

angr.analyses.decompiler.pattern_match.**linearize**(*graph*, *entry*)

Reverse post-order from `entry`, deterministic, with unreachable blocks appended.

RPO keeps single-entry regions contiguous, which is what the Outliner needs. Successors are visited highest address first: the one visited first ends up last, so the body of an `if (err) { ...; return; }`, usually the fall-through at the lower address, comes right after its condition instead of at the end of the function.

**Return type**
list[Block]

**Parameters**

- **graph** (*networkx.DiGraph[Block]*)
- **entry** (Block)

angr.analyses.decompiler.pattern_match.**match_shape**(*node*, *tree*)

How well node fits the shape tree of one token.

**Return type**
*Fit*

**Parameters**

- **node** (PatternNode)
- **tree** (*tuple[str, tuple[ShapeTree, ...]]*)

angr.analyses.decompiler.pattern_match.**materialize**(*graph*, *stream*, *region*, *block_addr_alloc*, ***, *split_tail=True*, *idx_alloc=None*)

Split the boundary blocks in place so region becomes block-aligned.

Returns the (src_loc, frontier) pair to hand to the Outliner. graph is mutated. With split_tail=False only the head is split, which is what the caller wants when it intends to let the Outliner derive its own frontier: the tail boundary is then chosen by liveness, not by the interval.

**Return type**
tuple[tuple[int, int], set[tuple[int, int]]]

**Parameters**

- **graph** (*networkx.DiGraph[Block]*)
- **stream** (TokenStream)
- **region** (Region)
- **block_addr_alloc** (*Callable[[], int]*)
- **split_tail** (*bool*)
- **idx_alloc** (*Callable[[], int] | None*)

angr.analyses.decompiler.pattern_match.**parse_shape**(*shape*)

"Asn(V,Add(V,C))" -> ("Asn", (("V", ()), ("Add", (("V", ()), ("C", ())))))).

**Return type**
tuple[str, tuple[ShapeTree, ...]]

**Parameters**
**shape** (*str*)

angr.analyses.decompiler.pattern_match.**search**(*pattern*, *stream*, *params=None*, *checkpoint=None*)

Every non-overlapping occurrence of pattern in stream scoring at least params.min_identity in similarity, best first. checkpoint is called from the alignment loops; see *priority.Checkpoint*.

The stream must come from tokenize_for_templates() (or an equivalent *TEMPLATE_TOKENIZER* configuration), or shapes will not line up with the template's rendering.

**Return type**
list[TemplateMatch]

**Parameters**

- **pattern** (KnownPattern | dsl.PatternNode)
- **stream** (TokenStream)
- **params** (AlignParams | *None*)
- **checkpoint** (*Callable[[], None] | None*)

angr.analyses.decompiler.pattern_match.**select_disjoint**(*clusters*, *overlap_ratio=0.25*)

Greedily pick the highest-savings clusters whose occurrences do not collide.

Repeat finding legitimately reports the same code at several granularities (the whole inlined region, and the hot loop inside it). Outlining needs one decision per token, so callers that want to rewrite the graph take this subset while keeping the full list for reporting.

**Return type**
list[*PatternCluster*]

**Parameters**

- **clusters** (*list[PatternCluster]*)
- **overlap_ratio** (*float*)

angr.analyses.decompiler.pattern_match.**shape_of**(*node*)

The shape a fully concrete node renders to, or None if it has a wildcard.

**Return type**
str | None

**Parameters**
**node** (PatternNode)

angr.analyses.decompiler.pattern_match.**snap**(*stream*, *graph*, *interval*, ***, *allow_split=True*, *entry_loc=None*)

Map `interval` onto blocks and decide whether the Outliner can take it.

**Return type**
*Region*

**Parameters**

- **stream** (TokenStream)
- **graph** (*networkx.DiGraph[Block]*)
- **interval** (Interval)
- **allow_split** (*bool*)
- **entry_loc** (*Address | None*)

angr.analyses.decompiler.pattern_match.**template_leaves**(*pattern*)

The template's leaf statements in stream order.

A statement sequence is already in order. A graph pattern is flattened the way the tokenizer linearizes a function, reverse post-order from the entry, so that a template lifted from a selection lines up with the stream that produced it.

**Return type**
list[*PAssign* | *PStore* | *PCallStmt* | *PCondJump* | *PReturn* | *PAnyStmt*]

**Parameters**
**pattern** (KnownPattern | PatternNode)

angr.analyses.decompiler.pattern_match.**tokenize**(*graph*, *entry*, ***, *kb=None*, *loader=None*, *max_depth=5*, *keep_vvar_category=True*, *keep_sizes=True*, *const_mode='abstract'*, *skip_labels=False*, *skip_phis=False*, *compute_bags=False*, *skip_conversions=False*, *skip_dephi=False*)

Linearize graph from entry and canonicalize every statement into a token.

skip_dephi leaves out the copies SSA destruction adds (tagged dephi): they appear after the stage the pattern pass runs at, so a pattern must not depend on them.

**Return type**
*TokenStream*

**Parameters**

- **graph** (*networkx.DiGraph[Block]*)
- **entry** (Block)
- **kb** (KnowledgeBase | *None*)
- **max_depth** (*int*)
- **keep_vvar_category** (*bool*)
- **keep_sizes** (*bool*)
- **const_mode** (*str*)
- **skip_labels** (*bool*)
- **skip_phis** (*bool*)
- **compute_bags** (*bool*)
- **skip_conversions** (*bool*)
- **skip_dephi** (*bool*)

angr.analyses.decompiler.pattern_match.**tokenize_for_templates**(*graph*, *entry*, ***, *kb=None*, *loader=None*)

A stream a template can be searched in: the tokenizer under the template settings.

**Return type**
*TokenStream*

**Parameters**

- **graph** (*networkx.DiGraph[Block]*)
- **entry** (Block)
- **kb** (KnowledgeBase | *None*)

angr.analyses.decompiler.pattern_match.**verify**(*match*, *pattern*, *stream*, *ctx=None*, *checkpoint=None*)

Run every placed leaf's structural match on its statement, sharing one binding environment, and record the outcome on the match.

Shapes erase constants, variable identity and sizes below the statement, so a leaf can fit a token's shape while its PConst(value=...) or a repeated capture name does not hold. A required leaf that fails leaves the match unverified; an optional one is merely noted on its column.

**Return type**
TemplateMatch

**Parameters**

- **match** (*TemplateMatch*)
- **pattern** (KnownPattern | dsl.PatternNode)

- **stream** (TokenStream)
- **ctx** (MatchCtx | None)
- **checkpoint** (Callable[[], None] | None)

### Submodules

| | |
|---|---|
| *align* | Fuzzy common-substring discovery over a token stream. |
| *dedup* | `PatternDeduplicator`: outline discovered patterns and merge the sound ones. |
| *exact* | Tier 2: maximal *exactly* shared sub-ranges inside a fuzzy family. |
| *finder* | `FuzzyPatternFinder`: discover fuzzy repeated code in a decompiled function. |
| *priority* | Keeping the pattern analyses from starving other threads, a GUI's in particular. |
| *region* | Turn a token interval into something `Outliner` accepts. |
| `search`(pattern, stream[, params, checkpoint]) | Every non-overlapping occurrence of `pattern` in `stream` scoring at least `params.min_identity` in similarity, best first. |
| *template* | Bridge between pattern-DSL nodes and the tokenizer's shape alphabet. |
| *tokenizer* | Turn an AIL graph into a linear token stream suitable for string algorithms. |

### angr.analyses.decompiler.pattern_match.align

Fuzzy common-substring discovery over a token stream.

The algorithm is sparse local self-alignment, the BLAST/MUMmer family:

1. **Seed** – index every k-gram of the token stream. Buckets whose multiplicity exceeds `max_seed_multiplicity` are masked out; without this low-complexity filter, ubiquitous tokens generate a quadratic number of seed pairs. Optional winnowing (Schleimer et al., SIGMOD'03) keeps only the minimum hash in each window of `window` consecutive k-grams, which thins the seed set while still guaranteeing that any exact match of length `>= k + window - 1` produces a seed.
2. **Chain** – every seed pair `(i, j)` votes for diagonal `d = j - i`. Per diagonal the seed positions are cut into runs separated by more than `max_gap`, and runs on nearby diagonals are fused only when they really overlap (see `_merge_diagonals()`).
3. **Align** – each candidate is refined by a banded Smith-Waterman with affine gaps over the substitution model, yielding exact boundaries and an identity ratio. The band absorbs indels, so a repeat whose seeds landed on two diagonals is still recovered as a single match.
4. **Cluster** – surviving alignments are merged into groups of `>= 2` occurrences by union-find over overlapping intervals, then de-overlapped by a weight-maximizing interval-scheduling pass.

Everything here is pure: it operates on lists of integer token ids and knows nothing about angr. *finder* supplies the ids.

**class** angr.analyses.decompiler.pattern_match.align.**Interval**

Bases: object

A half-open token range `[start, end)`.

**start:** int

**end:** int

**overlaps**(*other*)

**Return type**
bool

**Parameters**
**other** (Interval)

**overlap_len**(*other*)

**Return type**
int

**Parameters**
**other** (Interval)

**__init__**(*start*, *end*)

**Parameters**

- **start** (*int*)
- **end** (*int*)

**Return type**
None

class angr.analyses.decompiler.pattern_match.align.**Alignment**

Bases: object

One fuzzy match between two token ranges.

**a:** *Interval*

**b:** *Interval*

**score:** float

**matched:** int

**columns:** int

**property identity:** float

**__init__**(*a*, *b*, *score*, *matched*, *columns*)

**Parameters**

- **a** (Interval)
- **b** (Interval)
- **score** (*float*)
- **matched** (*int*)
- **columns** (*int*)

**Return type**
None

class angr.analyses.decompiler.pattern_match.align.**PatternCluster**

Bases: object

A group of occurrences of one fuzzy pattern.

**occurrences:** list[*Interval*]

**score:** float

**identity:** float

**alignments:** list[*Alignment*]

**property size:** int

**property savings:** float

every occurrence but one disappears.

**Type**
Tokens removed by outlining

**spans**()

**Return type**
list[*Interval*]

**__init__**(*occurrences*, *score*, *identity*, *alignments=<factory>*)

**Parameters**

- **occurrences** (*list[Interval]*)
- **score** (*float*)
- **identity** (*float*)
- **alignments** (*list[Alignment]*)

**Return type**
None

class angr.analyses.decompiler.pattern_match.align.**AlignParams**

Bases: object

Knobs for the whole pipeline.

**k:** int = 4

**window:** int = 0

**max_seed_multiplicity:** int = 80

**min_anchors:** int = 4

**max_gap:** int = 30

**band:** int = 16

**pad:** int = 40

**match:** float = 3.0

**klass_match:** float = 1.0

**mismatch:** float = -2.0

**gap_open:** float = -4.0

**gap_extend:** float = -1.0

**min_score:** float = 40.0

**min_identity:** float = 0.5

**min_size:** int = 8

**min_occurrences:** int = 2

**max_candidates:** int = 4000

**overlap_ratio:** float = 0.5

**allow_tandem:** bool = False

**min_votes:** int = 5

a diagonal needs this many statements of the template voting for it to be aligned, or a quarter of the template's concrete statements if that is fewer, so small templates are never pruned

**Type**
template search

**__init__**(*k=4*, *window=0*, *max_seed_multiplicity=80*, *min_anchors=4*, *max_gap=30*, *band=16*, *pad=40*, *match=3.0*, *klass_match=1.0*, *mismatch=-2.0*, *gap_open=-4.0*, *gap_extend=-1.0*, *min_score=40.0*, *min_identity=0.5*, *min_size=8*, *min_occurrences=2*, *max_candidates=4000*, *overlap_ratio=0.5*, *allow_tandem=False*, *min_votes=5*)

**Parameters**

- **k** (*int*)
- **window** (*int*)
- **max_seed_multiplicity** (*int*)
- **min_anchors** (*int*)
- **max_gap** (*int*)
- **band** (*int*)
- **pad** (*int*)
- **match** (*float*)
- **klass_match** (*float*)
- **mismatch** (*float*)
- **gap_open** (*float*)
- **gap_extend** (*float*)
- **min_score** (*float*)
- **min_identity** (*float*)
- **min_size** (*int*)
- **min_occurrences** (*int*)

- **max_candidates** (*int*)
- **overlap_ratio** (*float*)
- **allow_tandem** (*bool*)
- **min_votes** (*int*)

**Return type**
None

**class** angr.analyses.decompiler.pattern_match.align.**ScoreModel**

Bases: object

Substitution score between two shape ids.

**__init__**(*klass_of_shape*, *params*, *glue=frozenset({})*)

**Parameters**

- **klass_of_shape** (*list[int]*)
- **params** (AlignParams)
- **glue** (*frozenset[int]*)

**glue**

control glue between blocks, which neither makes two stretches of code alike nor keeps them apart

**Type**
shape ids of unconditional jumps

angr.analyses.decompiler.pattern_match.align.**find_seeds**(*ids*, *params*, *segment=None*, *glue=frozenset({})*)

k-gram index, low-complexity-masked and optionally winnowed. With `segment`, a k-gram that crosses from one segment into another is not a seed; nor is one made of unconditional jumps alone.

**Return type**
dict[tuple[int, ...], list[int]]

**Parameters**

- **ids** (*list[int]*)
- **params** (AlignParams)
- **segment** (*list[int] | None*)
- **glue** (*frozenset[int]*)

angr.analyses.decompiler.pattern_match.align.**chain_seeds**(*buckets*, *params*, *segment=None*)

Group seed pairs by diagonal and cut them into colinear runs. With `segment`, a run also ends where either copy would cross into another segment.

Returns `(diagonal, start, end, anchors)` candidates, where `[start, end)` is the range in the *first* (lower-index) copy.

**Return type**
list[tuple[int, int, int, int]]

**Parameters**

- **buckets** (*dict[tuple[int, ...], list[int]]*)
- **params** (AlignParams)

- **segment** (*list[int] | None*)

angr.analyses.decompiler.pattern_match.align.**banded_sw**(*ids*, *a0*, *a1*, *b0*, *b1*, *band*, *score*, *params*, *checkpoint=None*)

Banded local alignment with affine gaps, restricted to `|i - j| <= band`.

Two unconditional jumps (`score.glue`) lined up score nothing, and such a column counts toward neither the matched columns nor the columns. Skipping one is free when the statements after it on both sides are equal, and costs the usual gap otherwise: free skips everywhere let an alignment run on from one copy into the next, since reverse post-order often places copies side by side.

**Return type**
*Alignment* | None

**Parameters**

- **ids** (*list[int]*)
- **a0** (*int*)
- **a1** (*int*)
- **b0** (*int*)
- **b1** (*int*)
- **band** (*int*)
- **score** (ScoreModel)
- **params** (AlignParams)
- **checkpoint** (Callable[[], None] | None)

angr.analyses.decompiler.pattern_match.align.**refine_candidates**(*ids*, *candidates*, *score*, *params*, *checkpoint=None*, *segment=None*)

Run banded Smith-Waterman on every chained candidate and keep the good ones. With `segment`, each copy's window is clipped to the segment its seed lies in.

**Return type**
list[*Alignment*]

**Parameters**

- **ids** (*list[int]*)
- **candidates** (*list[tuple[int, int, int, int]]*)
- **score** (ScoreModel)
- **params** (AlignParams)
- **checkpoint** (Callable[[], None] | None)
- **segment** (*list[int] | None*)

angr.analyses.decompiler.pattern_match.align.**cluster_alignments**(*alignments*, *params*)

Merge pairwise alignments into groups of >= `min_occurrences` occurrences.

Alignments are clustered separately per length class (powers of two). Clustered together, a long alignment that runs through several neighbouring copies absorbed the short alignments of each copy: its interval replaced theirs, and one family came out with a few long occurrences instead of many short ones.

**Return type**
list[*PatternCluster*]

**Parameters**

- **alignments** (*list[Alignment]*)
- **params** (AlignParams)

angr.analyses.decompiler.pattern_match.align.**select_disjoint**(*clusters*, *overlap_ratio=0.25*)

Greedily pick the highest-savings clusters whose occurrences do not collide.

Repeat finding legitimately reports the same code at several granularities (the whole inlined region, and the hot loop inside it). Outlining needs one decision per token, so callers that want to rewrite the graph take this subset while keeping the full list for reporting.

**Return type**
list[*PatternCluster*]

**Parameters**

- **clusters** (*list[PatternCluster]*)
- **overlap_ratio** (*float*)

angr.analyses.decompiler.pattern_match.align.**discover**(*ids*, *klass_of_shape*, *params=None*, *checkpoint=None*, *segment=None*, *glue=frozenset({})*)

Full pipeline: seed -> chain -> align -> cluster. `checkpoint` is called from the alignment loops, where the time goes; see *priority.Checkpoint*. `segment` gives each token a segment number that no occurrence may cross out of, and `glue` the shape ids of unconditional jumps, which score nothing and cost nothing to skip.

**Return type**
list[*PatternCluster*]

**Parameters**

- **ids** (*list[int]*)
- **klass_of_shape** (*list[int]*)
- **params** (AlignParams | *None*)
- **checkpoint** (Callable[[], *None*] | *None*)
- **segment** (*list[int]* | *None*)
- **glue** (*frozenset[int]*)

### angr.analyses.decompiler.pattern_match.dedup

`PatternDeduplicator`: outline discovered patterns and merge the sound ones.

Extraction happens in two steps.

*Outlining* lifts every selected region into its own function via `Outliner`. This always applies and is what removes the duplicated bulk from the parent.

*Merging* then folds several outlined callees into a single shared function. This is only sound when the callees are identical modulo constants, so each group is re-verified at unlimited canonicalization depth (the shapes used for discovery are depth-limited and would not prove it), the argument lists are put into a canonical order, and the constants that actually differ are lifted into extra parameters passed by each call site. Anything that fails a check is left outlined but unmerged and reported, never merged approximately.

`granularity` selects what gets outlined:

**"occurrence"**
Each fuzzy occurrence becomes its own function. Maximum bulk removal from the parent; merging usually finds nothing, because near-duplicates that align at 90% are not identical.

**"core"**
Only the exactly-shared cores are outlined. Every member of a core group is identical modulo constants by construction, so these always merge.

**class** angr.analyses.decompiler.pattern_match.dedup.**OutlinedRegion**

Bases: object

One region that was successfully lifted into its own function.

**group_key:** tuple

**interval:** *Interval*

**src_loc:** tuple[int, int]

**call_loc:** tuple[int, int]

**child_func:** *Function*

**child_graph:** networkx.DiGraph[Block]

**child_args:** list[*VirtualVariable*]

**consts:** list[int]

**const_bits:** list[int]

**jump_target_consts:** set[int]
indices into `consts` that are block addresses, meaningless across copies

**call_target_consts:** set[int]
indices into `consts` that name a callee, which copies must agree on

**shape:** tuple[str, ...] = ()

**auto_frontier:** bool = False

**property statements:** int
Statements actually moved into the callee.

With a derived frontier this is not the interval length: the Outliner picks its own boundary, so the region it lifts can be smaller (or larger) than the interval that pointed at it.

**__init__**(*group_key*, *interval*, *src_loc*, *call_loc*, *child_func*, *child_graph*, *child_args*, *consts=<factory>*, *const_bits=<factory>*, *jump_target_consts=<factory>*, *call_target_consts=<factory>*, *shape=()*, *auto_frontier=False*)

**Parameters**

- **group_key** (*tuple*)
- **interval** (Interval)
- **src_loc** (*Address*)
- **call_loc** (*Address*)
- **child_func** (Function)

- **child_graph** (*networkx.DiGraph[Block]*)
- **child_args** (*list[VirtualVariable]*)
- **consts** (*list[int]*)
- **const_bits** (*list[int]*)
- **jump_target_consts** (*set[int]*)
- **call_target_consts** (*set[int]*)
- **shape** (*tuple[str, ...]*)
- **auto_frontier** (*bool*)

**Return type**
None

**class** angr.analyses.decompiler.pattern_match.dedup.**MergeGroup**

Bases: object

Several outlined regions folded into one shared function.

**name:** str

**members:** list[*OutlinedRegion*]

**lifted_const_indices:** list[int]

**property size:** int

**__init__**(*name*, *members*, *lifted_const_indices=<factory>*)

**Parameters**

- **name** (*str*)
- **members** (*list[OutlinedRegion]*)
- **lifted_const_indices** (*list[int]*)

**Return type**
None

**class** angr.analyses.decompiler.pattern_match.dedup.**DedupResult**

Bases: object

What *PatternDeduplicator* did.

**graph:** networkx.DiGraph[Block]

**outlined:** list[*OutlinedRegion*]

**groups:** list[*MergeGroup*]

**skipped:** list[tuple[*Interval*, str]]

**property statements_removed:** int

Statements actually moved out of the parent.

__init__(*graph*, *outlined=<factory>*, *groups=<factory>*, *skipped=<factory>*)

**Parameters**

- **graph** (*networkx.DiGraph[Block]*)
- **outlined** (*list[OutlinedRegion]*)
- **groups** (*list[MergeGroup]*)
- **skipped** (*list[tuple[Interval, str]]*)

**Return type**
None

angr.analyses.decompiler.pattern_match.dedup.**graph_problems**(*graph*, *func_addr=None*)

Structural invariants the decompiler relies on, checked after an outline.

Three things go wrong in practice, and all three surface far downstream as an unrelated crash, so they are caught here instead:

- A phi keeps sourcing a block that is gone. The Outliner keeps the source block's phis in the caller, moves every block the region reaches into the callee, and rewrites frontier phis to the call or dispatcher block; `materialize` splits a head's phis off so a loop back to it exits the region. What is left is a frontier phi reached through several new predecessors at once, which `_update_phi_stmts` leaves alone.
- Two blocks end up sharing `(addr, idx)`. `GraphDephicationVVarMapping` keys blocks by that pair in a plain dict, so one silently shadows the other and statement-index lookups land in the wrong block.
- A vvar gains a second definition. Definition locations are keyed by varid in a plain dict too, so the second write wins and the recorded index then points at an unrelated statement.

Outlines that introduce any of these are rolled back rather than handed on.

**Return type**
list[str]

**Parameters**

- **graph** (*networkx.DiGraph[Block]*)
- **func_addr** (*int | None*)

angr.analyses.decompiler.pattern_match.dedup.**normalize_call_width**(*graph*, *call_loc*)

Rebuild a synthesized call at the width of the variable it is assigned to.

The Outliner mints the callsite at return-register width, then overwrites the destination with the region's live-out variable, which is often narrower. Variable recovery later evaluates the assignment and dies on the width mismatch ("args' length must all be equal"), so fix it at the source.

**Return type**
bool

**Parameters**

- **graph** (*networkx.DiGraph[Block]*)
- **call_loc** (*Address*)

angr.analyses.decompiler.pattern_match.dedup.**callee_shape**(*graph*)

Full-depth canonical shape of a callee body, for merge verification.

Discovery uses depth-limited shapes, which cannot prove two bodies equal: anything below the depth cut renders as `?`. Merging re-derives the shape with no depth limit so equality really means identical modulo constants.

**Return type**
tuple[str, ...]

**Parameters**
**graph** (*networkx.DiGraph[Block]*)

angr.analyses.decompiler.pattern_match.dedup.**callee_consts**(*graph*)

Const values and widths of a callee body, ordered as in *callee_shape()*, with the indices that are jump targets and those that are call targets.

**Return type**
tuple[list[int], list[int], set[int], set[int]]

**Parameters**
**graph** (*networkx.DiGraph[Block]*)

angr.analyses.decompiler.pattern_match.dedup.**canonical_arg_order**(*graph*, *args*)

Order `args` by first use in the callee body.

The Outliner derives its interface from a dict of definitions, so two structurally identical callees can end up with their parameters in different orders. Sorting by first use makes the k-th parameter mean the same thing in every member of a merge group.

**Return type**
list[*VirtualVariable*]

**Parameters**

- **graph** (*networkx.DiGraph[Block]*)
- **args** (*list[VirtualVariable]*)

**class** angr.analyses.decompiler.pattern_match.dedup.**PatternDeduplicator**

Bases: *Analysis*

Outline fuzzy patterns out of a function and merge the provably equal ones.

**Parameters**

- **func** (*Function*) – The function being rewritten.
- **ail_graph** (networkx.DiGraph[Block]) – Its AIL graph. Not mutated; a copy is rewritten.
- **patterns** (list[*FuzzyPattern*]) – Patterns from *FuzzyPatternFinder*.
- **granularity** (str) – `"core"` (default, always mergeable) or `"occurrence"` (maximum bulk removal).
- **merge** (bool) – Fold provably identical callees into one function.
- **frontier_mode** (str) – `"region"` outlines exactly the discovered interval; `"fallback"` (default) additionally retries regions that are not single-entry by letting the Outliner derive its own frontier.
- **max_auto_blocks** (int) – Bound, as a multiple of the region's block count, on how large a derived frontier may grow.
- **min_auto_ratio** (float) – Smallest fraction of the region a derived frontier may cover before the outline is judged unrelated to the pattern and rolled back.
- **name_prefix** (str) – Prefix for synthesized function names.

**__init__**(*func*, *ail_graph*, *patterns*, *stream*, *, *granularity='core'*, *merge=True*, *name_prefix='fuzzy'*, *vvar_id_start=53248*, *block_addr_start=2882338816*, *const_param_stack_base=-65536*, *min_group_size=2*, *validate=True*, *frontier_mode='fallback'*, *max_auto_blocks=3*, *min_auto_ratio=0.5*)

**Parameters**

- **func** (Function)
- **ail_graph** (*networkx.DiGraph[Block]*)
- **patterns** (*list[FuzzyPattern]*)
- **stream** (TokenStream)
- **granularity** (*str*)
- **merge** (*bool*)
- **name_prefix** (*str*)
- **vvar_id_start** (*int*)
- **block_addr_start** (*int*)
- **const_param_stack_base** (*int*)
- **min_group_size** (*int*)
- **validate** (*bool*)
- **frontier_mode** (*str*)
- **max_auto_blocks** (*int*)
- **min_auto_ratio** (*float*)

**summary**()

**Return type**
str

### angr.analyses.decompiler.pattern_match.exact

Tier 2: maximal *exactly* shared sub-ranges inside a fuzzy family.

Tier 1 (*align*) discovers that a set of regions are near-duplicates. That is enough to understand a binary, but not enough to merge them: two regions that align at 90% still differ somewhere, and collapsing them into one function would be wrong.

This module finds the sub-ranges on which the occurrences agree *exactly* on canonical shapes. Because *tokenizer* already abstracts constants out of a shape, "exactly equal shapes" means "identical modulo constants" – the classic Type-2 clone. Those ranges can be outlined into a single shared function with the differing constants lifted into extra parameters, without changing semantics.

Cores are extracted greedily longest-first; each accepted core masks the token ranges it consumed, and the search continues on the surviving fragments.

**class** angr.analyses.decompiler.pattern_match.exact.**ExactCore**

Bases: object

A range on which several occurrences agree exactly on canonical shapes.

**occurrences:** list[*Interval*]

**length:** *int*

**property support:** *int*

**property savings:** *int*

**__init__**(*occurrences*, *length*)

**Parameters**

- **occurrences** (*list[Interval]*)
- **length** (*int*)

**Return type**
None

angr.analyses.decompiler.pattern_match.exact.**find_exact_cores**(*ids*, *occurrences*, *, *min_len=4*, *min_support=2*, *max_cores=32*)

Greedily extract maximal exactly-shared cores from a fuzzy family.

**Return type**
list[*ExactCore*]

**Parameters**

- **ids** (*list[int]*)
- **occurrences** (*list[Interval]*)
- **min_len** (*int*)
- **min_support** (*int*)
- **max_cores** (*int*)

### angr.analyses.decompiler.pattern_match.finder

FuzzyPatternFinder: discover fuzzy repeated code in a decompiled function.

class angr.analyses.decompiler.pattern_match.finder.**PatternOccurrence**

Bases: object

One occurrence of a discovered pattern, with its outlining verdict.

**interval:** *Interval*

**region:** *Region*

**property outlinable:** *bool*

**property block_locs:** *list[tuple[int, int]]*

**__init__**(*interval*, *region*)

**Parameters**

- **interval** (Interval)
- **region** (Region)

**Return type**
None

angr.analyses.decompiler.pattern_match.finder.**STATEMENTS_ANY = 'any'**
statements of an occurrence may come from anywhere in the function's block order

angr.analyses.decompiler.pattern_match.finder.**STATEMENTS_FOLLOW = 'follow'**
an occurrence continues only into a block that follows in the control flow

angr.analyses.decompiler.pattern_match.finder.**STATEMENTS_CONSECUTIVE = 'consecutive'**
consecutive lines of the pseudocode

**Type**
an occurrence is one straight run of code

**class** angr.analyses.decompiler.pattern_match.finder.**FuzzyPattern**
Bases: object

A family of near-duplicate regions, plus the sub-ranges they share exactly.

**cluster:** *PatternCluster*

**occurrences:** list[*PatternOccurrence*]

**cores:** list[*ExactCore*]

**core_occurrences:** list[list[*PatternOccurrence*]]

**property identity:** float

**property size:** int

**property savings:** float

**property sound_savings:** int
Tokens removable without changing semantics, i.e. via the exact cores.

**property outlinable_occurrences:** list[*PatternOccurrence*]

**__init__**(*cluster*, *occurrences*, *cores=<factory>*, *core_occurrences=<factory>*)

**Parameters**
- **cluster** (PatternCluster)
- **occurrences** (*list[*PatternOccurrence*]*)
- **cores** (*list[*ExactCore*]*)
- **core_occurrences** (*list[list[*PatternOccurrence*]]*)

**Return type**
None

**class** angr.analyses.decompiler.pattern_match.finder.**FuzzyPatternFinder**
Bases: *Analysis*

Find fuzzy repeated code in an AIL graph.

Duplicated inlined code (obfuscator-generated decryption stubs, expanded macros, copies of an inlined helper) is rarely byte-identical: constants differ per site and optimizers reorder and reassociate. Exact matching finds nothing, so this analysis linearizes the graph into a canonical token stream and runs a sparse local self-alignment over it (see *align*).

Two tiers of result are produced. `patterns` holds the fuzzy families, which is what you want to understand a function. Each family also carries `cores`: the sub-ranges its members agree on *exactly*, which is what you can soundly merge into a single shared function.

**Parameters**

- **func** (*Function*) – The function being analyzed.
- **ail_graph** (networkx.DiGraph[Block]) – Its AIL graph, e.g. `Decompiler.ail_graph`.
- **params** (*AlignParams* | None) – Alignment knobs; see *AlignParams*.
- **disjoint** (bool) – Keep only a non-overlapping subset of families (what outlining needs). `all_patterns` always has the full list.
- **min_core_len** (int) – Shortest exact core worth reporting.
- **resolve_calls** (bool) – Render call targets by callee name, which makes calls strong anchors for the aligner.

**__init__**(*func*, *ail_graph*, ***, *params=None*, *disjoint=True*, *min_core_len=4*, *min_core_support=2*, *max_depth=5*, *const_mode='abstract'*, *skip_labels=True*, *skip_phis=True*, *skip_dephi=True*, *resolve_calls=True*, *entry=None*, *low_priority=False*, *checkpoint=None*, *statements='any'*)

**Parameters**

- **func** (Function)
- **ail_graph** (*networkx.DiGraph[Block]*)
- **params** (AlignParams | *None*)
- **disjoint** (*bool*)
- **min_core_len** (*int*)
- **min_core_support** (*int*)
- **max_depth** (*int*)
- **const_mode** (*str*)
- **skip_labels** (*bool*)
- **skip_phis** (*bool*)
- **skip_dephi** (*bool*)
- **resolve_calls** (*bool*)
- **entry** (Block | *None*)
- **low_priority** (*bool*)
- **checkpoint** (Callable[[], None] | *None*)
- **statements** (*str*)

**statements**

how the statements of one occurrence may follow each other; see STATEMENTS_MODES

**stream:** *TokenStream*

**all_patterns:** list[*FuzzyPattern*]

**patterns:** list[*FuzzyPattern*]

**summary**(*limit=20*)

A human-readable report of what was found.

**Return type**
str

**Parameters**
**limit** (*int*)

### angr.analyses.decompiler.pattern_match.priority

Keeping the pattern analyses from starving other threads, a GUI's in particular.

angr.analyses.decompiler.pattern_match.priority.**YIELD_INTERVAL = 0.02**

seconds between two yields

angr.analyses.decompiler.pattern_match.priority.**YIELD_SLEEP = 0.001**

how long a yield sleeps; a microsecond is too short for the OS to wake the GUI thread before this one takes the GIL back

**class** angr.analyses.decompiler.pattern_match.priority.**Checkpoint**

Bases: object

Called from inside hot loops, as often as is convenient.

Every `freq` calls it looks at the clock, and at most once per `interval` seconds it sleeps for `sleep` seconds to let other threads take the GIL, as the CFG's low-priority mode does, and then runs `callback`. The callback may raise to abort the analysis; a UI uses that to cancel.

**__init__**(*low_priority=True*, *callback=None*, *freq=1*, *interval=0.02*, *sleep=0.001*)

**Parameters**

- **low_priority** (*bool*)
- **callback** (*Callable[[], None] | None*)
- **freq** (*int*)
- **interval** (*float*)
- **sleep** (*float*)

**low_priority**

**callback**

**freq**

**interval**

**sleep**

### angr.analyses.decompiler.pattern_match.region

Turn a token interval into something `Outliner` accepts.

The Outliner takes a single entry location plus a frontier and lifts everything between them into a new function. A token interval discovered by *align* does not automatically satisfy that: it may start or end in the middle of a block, and the blocks it covers may be entered from outside.

*snap()* reports whether an interval can be outlined and why not when it cannot; *materialize()* performs the block splits and returns the final `(src_loc, frontier)`.

class angr.analyses.decompiler.pattern_match.region.**Region**

Bases: object

An interval mapped onto AIL blocks, with its outlinability verdict.

**interval:** *Interval*

**block_locs:** list[tuple[int, int]]

**src_loc:** tuple[int, int]

**frontier:** set[tuple[int, int]]

**head_split:** int = 0

**tail_split:** int = 0

**outlinable:** bool = False

**reason:** str = ''

property **needs_split:** bool

**__init__**(*interval*, *block_locs*, *src_loc*, *frontier=<factory>*, *head_split=0*, *tail_split=0*, *outlinable=False*, *reason=''*)

**Parameters**

- **interval** (Interval)
- **block_locs** (*list[tuple[int, int]]*)
- **src_loc** (*tuple[int, int]*)
- **frontier** (*set[tuple[int, int]]*)
- **head_split** (*int*)
- **tail_split** (*int*)
- **outlinable** (*bool*)
- **reason** (*str*)

**Return type**
None

angr.analyses.decompiler.pattern_match.region.**snap**(*stream*, *graph*, *interval*, ***, *allow_split=True*, *entry_loc=None*)

Map `interval` onto blocks and decide whether the Outliner can take it.

**Return type**
*Region*

**Parameters**

- **stream** (TokenStream)
- **graph** (*networkx.DiGraph[Block]*)
- **interval** (Interval)
- **allow_split** (*bool*)
- **entry_loc** (*Address | None*)

angr.analyses.decompiler.pattern_match.region.**largest_single_entry_subrun**(*stream*, *graph*, *interval*, ***, *entry_loc=None*, *min_ratio=0.0*)

The largest outlinable region inside `interval`, made of whole consecutive blocks of it, or None.

A run of tokens is not always a single-entry region: reverse post-order interleaves blocks from different parts of the CFG, so one copy of an idiom can still be jumped into from elsewhere. Some consecutive sub-run of its blocks usually is single-entry, and the largest one is what can be outlined under the pattern's name. `min_ratio` is the smallest share of the interval's tokens the sub-run must cover to count.

**Return type**
*Region* | None

**Parameters**

- **stream** (TokenStream)
- **graph** (*networkx.DiGraph[Block]*)
- **interval** (Interval)
- **entry_loc** (*Address | None*)
- **min_ratio** (*float*)

angr.analyses.decompiler.pattern_match.region.**fallback_idx_alloc**(*graph*)

An AIL index allocator for a caller without a Manager: seeded past every index already in `graph`, since a rebuilt statement must not reuse one an existing expression holds.

**Return type**
Callable[[], int]

**Parameters**
**graph** (*networkx.DiGraph[Block]*)

angr.analyses.decompiler.pattern_match.region.**materialize**(*graph*, *stream*, *region*, *block_addr_alloc*, ***, *split_tail=True*, *idx_alloc=None*)

Split the boundary blocks in place so `region` becomes block-aligned.

Returns the `(src_loc, frontier)` pair to hand to the Outliner. `graph` is mutated. With `split_tail=False` only the head is split, which is what the caller wants when it intends to let the Outliner derive its own frontier: the tail boundary is then chosen by liveness, not by the interval.

**Return type**
tuple[tuple[int, int], set[tuple[int, int]]]

**Parameters**

- **graph** (*networkx.DiGraph[Block]*)
- **stream** (TokenStream)
- **region** (Region)
- **block_addr_alloc** (*Callable[[], int]*)
- **split_tail** (*bool*)
- **idx_alloc** (*Callable[[], int] | None*)

### angr.analyses.decompiler.pattern_match.search

angr.analyses.decompiler.pattern_match.**search**(*pattern*, *stream*, *params=None*, *checkpoint=None*)

Every non-overlapping occurrence of `pattern` in `stream` scoring at least `params.min_identity` in similarity, best first. `checkpoint` is called from the alignment loops; see *priority.Checkpoint*.

The stream must come from `tokenize_for_templates()` (or an equivalent *TEMPLATE_TOKENIZER* configuration), or shapes will not line up with the template's rendering.

**Return type**
list[TemplateMatch]

**Parameters**

- **pattern** (KnownPattern | dsl.PatternNode)
- **stream** (TokenStream)
- **params** (AlignParams | *None*)
- **checkpoint** (Callable*[[], None]* | *None*)

### angr.analyses.decompiler.pattern_match.template

Bridge between pattern-DSL nodes and the tokenizer's shape alphabet.

The fuzzy matcher aligns *shapes* (see *tokenizer*), while a user-authored pattern is a tree of *dsl* nodes. This module renders a node into the same alphabet, so a template can seed and score against a token stream:

- *shape_of()* gives the one shape a fully concrete node stands for, or None when the node has a wildcard anywhere and stands for many.
- *match_shape()* says how well a node fits a stream token's shape: exactly, up to operator class, or not at all. Wildcards accept anything.

Both mirror *AILCanonicalizer* rule for rule under the *TEMPLATE_TOKENIZER* settings, and `tests/analyses/decompiler/test_pattern_match_template.py` checks the mirror against every statement of a real function.

angr.analyses.decompiler.pattern_match.template.**TEMPLATE_TOKENIZER: dict = {'const_mode': 'abstract', 'keep_sizes': True, 'keep_vvar_category': False, 'max_depth': 5, 'skip_conversions': True, 'skip_dephi': True, 'skip_labels': True, 'skip_phis': True}**

tokenizer settings a template is rendered under; a stream to search must use them

angr.analyses.decompiler.pattern_match.template.**ShapeTree**

a shape string parsed into `(head, children)`

alias of tuple[str, tuple[ShapeTree, ...]]

**class** angr.analyses.decompiler.pattern_match.template.**Fit**

Bases: IntEnum

How well a node fits a shape. Ordered so `min` combines children.

**NONE = 0**

**KLASS = 1**

**EXACT = 2**

**__new__**(*value*)

angr.analyses.decompiler.pattern_match.template.**parse_shape**(*shape*)

`"Asn(V,Add(V,C))"` -> `("Asn", (("V", ()), ("Add", (("V", ()), ("C", ()))))).`

**Return type**
tuple[str, tuple[ShapeTree, ...]]

**Parameters**
**shape** (*str*)

angr.analyses.decompiler.pattern_match.template.**shape_of**(*node*)

The shape a fully concrete node renders to, or None if it has a wildcard.

**Return type**
str | None

**Parameters**
**node** (PatternNode)

angr.analyses.decompiler.pattern_match.template.**match_shape**(*node*, *tree*)

How well `node` fits the shape `tree` of one token.

**Return type**
*Fit*

**Parameters**

- **node** (PatternNode)
- **tree** (*tuple[str, tuple[ShapeTree, ...]]*)

### angr.analyses.decompiler.pattern_match.tokenizer

Turn an AIL graph into a linear token stream suitable for string algorithms.

The stream is what the fuzzy matcher in *align* operates on. Every AIL statement becomes exactly one token, canonicalized at three levels:

**shape**
A depth-limited canonical rendering of the statement tree with constants, variable identities and addresses abstracted away. Two statements share a shape iff they are the "same operation" modulo those details. This is the exact-match key used for seeding.

**klass**
`shape` with operators replaced by their class (ARITH/LOGIC/SHIFT/...). Used to give partial credit when two statements differ only in which arithmetic operator they use.

**bag**
Multiset of operator names at every depth, for an optional graded score.

Keeping the operator name in `shape` and folding it only in `klass` is deliberate: the fuzziness belongs in the substitution score, not in the token, so that `Add` vs `Sub` costs a little while `Add` vs `Store` costs a lot.

**class** angr.analyses.decompiler.pattern_match.tokenizer.**TokenLoc**

Bases: object

Where a token came from.

**block_addr:** int

**block_idx:** int

**stmt_idx:** int

**block_pos:** int

**ins_addr:** int | None

**property block_loc:** tuple[int, int]

**__init__**(*block_addr*, *block_idx*, *stmt_idx*, *block_pos*, *ins_addr*)

**Parameters**

- **block_addr** (*int*)
- **block_idx** (*int*)
- **stmt_idx** (*int*)
- **block_pos** (*int*)
- **ins_addr** (*int | None*)

**Return type**
None

**class** angr.analyses.decompiler.pattern_match.tokenizer.**TokenStream**

Bases: object

A linearized, canonicalized view of an AIL graph.

**blocks:** list[Block]

**block_span:** dict[tuple[int, int], tuple[int, int]]

**locs:** list[*TokenLoc*]

**shapes:** list[str]

**klasses:** list[str]

**bags:** list[Counter]

**shape_ids:** list[int]

**klass_ids:** list[int]

**shape_vocab:** list[str]

**klass_vocab:** list[str]

**klass_of_shape:** list[int]

**kb:** *KnowledgeBase* | None = None
the knowledge base the callee names were resolved against, for a verifier to reuse

**block_locs_in**(*start*, *end*)
Block locations touched by tokens [start, end), in linearization order.

**Return type**
list[tuple[int, int]]

**Parameters**

- **start** (*int*)
- **end** (*int*)

covers_whole_block(*start*, *end*, *block_loc*)

**Return type**
bool

**Parameters**

- **start** (*int*)
- **end** (*int*)
- **block_loc** (*tuple[int, int]*)

addr_range(*start*, *end*)

**Return type**
tuple[int | None, int | None]

**Parameters**

- **start** (*int*)
- **end** (*int*)

__init__(*blocks*, *block_span*, *locs*, *shapes*, *klasses*, *bags*, *shape_ids*, *klass_ids*, *shape_vocab=<factory>*, *klass_vocab=<factory>*, *klass_of_shape=<factory>*, *kb=None*)

**Parameters**

- **blocks** (*list[Block]*)
- **block_span** (*dict[Address, tuple[int, int]]*)
- **locs** (*list[TokenLoc]*)
- **shapes** (*list[str]*)
- **klasses** (*list[str]*)
- **bags** (*list[Counter]*)
- **shape_ids** (*list[int]*)
- **klass_ids** (*list[int]*)
- **shape_vocab** (*list[str]*)
- **klass_vocab** (*list[str]*)
- **klass_of_shape** (*list[int]*)
- **kb** (KnowledgeBase | *None*)

**Return type**
None

angr.analyses.decompiler.pattern_match.tokenizer.**is_dephi_copy**(*stmt*)

A copy SSA destruction added: it does not exist at the stage the pattern pass runs at.

**Return type**
bool

**Parameters**
**stmt** (Statement)

angr.analyses.decompiler.pattern_match.tokenizer.**is_glue_shape**(*shape*)

An unconditional jump: control glue between blocks, not a statement an idiom is made of.

**Return type**
bool

**Parameters**
**shape** (*str*)

**class** angr.analyses.decompiler.pattern_match.tokenizer.**AILCanonicalizer**

Bases: object

Renders AIL statements into canonical shape strings.

**__init__**(*, *max_depth=5*, *keep_vvar_category=True*, *keep_sizes=True*, *const_mode='abstract'*, *kb=None*, *block_pos=None*, *loader=None*, *skip_conversions=False*)

**Parameters**

- **max_depth** (*int*)
- **keep_vvar_category** (*bool*)
- **keep_sizes** (*bool*)
- **const_mode** (*str*)
- **kb** (KnowledgeBase | *None*)
- **block_pos** (*dict[Address, int] | None*)
- **skip_conversions** (*bool*)

**statement**(*stmt*, *cur_pos=None*)

**Return type**
str

**Parameters**

- **stmt** (Statement)
- **cur_pos** (*int | None*)

**bag**(*stmt*, *max_depth=8*)

**Return type**
Counter

**Parameters**

- **stmt** (Statement)
- **max_depth** (*int*)

**static klass_of**(*shape*)

Fold operator names in a shape string into operator classes, and variables of any category (VR, VS, ...) into V: the same idiom keeps a value in a register in one copy and on the stack in another.

**Return type**
str

**Parameters**
**shape** (*str*)

angr.analyses.decompiler.pattern_match.tokenizer.**linearize**(*graph*, *entry*)

Reverse post-order from `entry`, deterministic, with unreachable blocks appended.

RPO keeps single-entry regions contiguous, which is what the Outliner needs. Successors are visited highest address first: the one visited first ends up last, so the body of an `if (err) { ...; return; }`, usually the fall-through at the lower address, comes right after its condition instead of at the end of the function.

**Return type**
`list`[Block]

**Parameters**

- **graph** (*networkx.DiGraph*[Block])
- **entry** (Block)

angr.analyses.decompiler.pattern_match.tokenizer.**tokenize**(*graph*, *entry*, *, *kb=None*, *loader=None*, *max_depth=5*, *keep_vvar_category=True*, *keep_sizes=True*, *const_mode='abstract'*, *skip_labels=False*, *skip_phis=False*, *compute_bags=False*, *skip_conversions=False*, *skip_dephi=False*)

Linearize `graph` from `entry` and canonicalize every statement into a token.

`skip_dephi` leaves out the copies SSA destruction adds (tagged `dephi`): they appear after the stage the pattern pass runs at, so a pattern must not depend on them.

**Return type**
*TokenStream*

**Parameters**

- **graph** (*networkx.DiGraph*[Block])
- **entry** (Block)
- **kb** (KnowledgeBase | *None*)
- **max_depth** (*int*)
- **keep_vvar_category** (*bool*)
- **keep_sizes** (*bool*)
- **const_mode** (*str*)
- **skip_labels** (*bool*)
- **skip_phis** (*bool*)
- **compute_bags** (*bool*)
- **skip_conversions** (*bool*)
- **skip_dephi** (*bool*)

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.arm_cmpf

**class** angr.analyses.decompiler.peephole_optimizations.arm_cmpf.**ARMCmpF**

Bases: *PeepholeOptimizationExprBase*

Rewrites tests of ARM NZCV flags.

VEX lowers `vcmp` to `FPSCR = (FPSCR & 0x0fffffff) | nzcv(CmpF(a, b)) << 28` and `vmrs APSR_nzcv, fpscr` to a COPY of FPSCR's top nibble into the flags. The condition of the next branch then extracts the flag bits. This optimization rewrites the bit test by evaluating each CmpF outcome (seeing through the FPSCR definition in the same block, or its unique definition elsewhere in the function) and replacing by the equivalent comparison.

**NAME = 'Simplifying CmpF on ARM'**

**expr_classes = (<class 'angr.ailment.expression.Convert'>, <class 'angr.ailment.expression.BinaryOp'>)**

**__init__**(**args*, ***kwargs*)

**optimize**(*expr*, ***, *stmt_idx=None*, *block=None*, *block_defs=None*, ***kwargs*)

**Parameters**

- **expr** (Convert | BinaryOp)
- **stmt_idx** (*int* | *None*)
- **block_defs** (BlockDefs | *None*)

### angr.analyses.decompiler.peephole_optimizations.base

**class** angr.analyses.decompiler.peephole_optimizations.base.**PeepholeOptimizationStmtBase**

Bases: object

The base class for all peephole optimizations that are applied on AIL statements.

fixpoint_reached is an output parameter; it tells the caller whether this optimizer should run on this statement again (e.g., when statements prior to the current statement are optimized and changed). The caller sets fixpoint_reached to True before every *optimize()* call; the optimizer optionally sets it to False if it wants to be invoked again on the same statement.

So, fixpoint_reached should be set to (or kept) True if (a) the optimizer has optimized the statement and does not expect to optimize it ever again, or (b) the optimizer cannot ever optimize the statement.

**NAME = 'Peephole Optimization - Statement'**

**DESCRIPTION = 'Peephole Optimization - Statement'**

**stmt_classes = None**

**__init__**(*project*, *kb*, *ail_manager*, *func_addr=None*, *preserve_vvar_ids=None*, *type_hints=None*)

**Parameters**

- **project** (*Project | None*)
- **kb** (*KnowledgeBase | None*)
- **ail_manager** (*Manager*)
- **func_addr** (*int | None*)
- **preserve_vvar_ids** (*set[int] | None*)
- **type_hints** (*list[tuple[atoms.VirtualVariable | atoms.MemoryLocation, str]] | None*)

**project: *Project* | None**

**func_addr: int | None**

**preserve_vvar_ids: set[int]**

**type_hints: list[tuple[*VirtualVariable* | *MemoryLocation*, str]]**

**fixpoint_reached: bool**

**optimize**(*stmt*, *stmt_idx*, *block*, ***kwargs*)

**Parameters**

- **stmt_idx** (*int*)
- **block** (*Block*)

class angr.analyses.decompiler.peephole_optimizations.base.**PeepholeOptimizationMultiStmtBase**

Bases: object

The base class for all peephole optimizations that are applied on multiple AIL statements at once.

fixpoint_reached exists for uniformity but is unused. Multi-statement optimizers always run regardless of whether the statements have reached fixed points or not.

**NAME = 'Peephole Optimization - Multi-statement'**

**DESCRIPTION = 'Peephole Optimization - Multi-statement'**

**stmt_classes = None**

**__init__**(*project*, *kb*, *ail_manager*, *func_addr=None*, *preserve_vvar_ids=None*, *type_hints=None*)

**Parameters**

- **project** (*Project | None*)
- **kb** (*KnowledgeBase | None*)
- **ail_manager** (*Manager*)
- **func_addr** (*int | None*)
- **preserve_vvar_ids** (*set[int] | None*)
- **type_hints** (*list[tuple[atoms.VirtualVariable | atoms.MemoryLocation, str]] | None*)

**project: *Project* | None**

**project: *Project* | None**

**kb: *KnowledgeBase* | None**

**manager**

**func_addr: int | None**

**preserve_vvar_ids: set[int]**

**type_hints: list[tuple[*VirtualVariable* | *MemoryLocation*, str]]**

**fixpoint_reached: bool**

**optimize**(*expr*, ***, *stmt_idx=None*, *block=None*, ***kwargs*)

**Return type**
*Expression* | None

**Parameters**
**stmt_idx** (*int | None*)

**static find_definition**(*ail_expr*, *stmt_idx*, *block*)

**Return type**
None

**Parameters**

- **ail_expr** (*Expression*)
- **stmt_idx** (*int*)
- **block** (*Block*)

**static is_bool_expr**(*ail_expr*)

### angr.analyses.decompiler.peephole_optimizations.basepointeroffset_add_n

**class** angr.analyses.decompiler.peephole_optimizations.basepointeroffset_add_n.**BasePointerOffsetAddN**

Bases: *PeepholeOptimizationExprBase*

**NAME = '(Ptr - M) + N => Ptr - (M - N)'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.basepointeroffset_and_mask

**class** angr.analyses.decompiler.peephole_optimizations.basepointeroffset_and_mask.**BasePointerOffsetAndMask**

Bases: *PeepholeOptimizationExprBase*

**NAME = 'Ptr & mask => Ptr'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.bitwise_inserts

**class** angr.analyses.decompiler.peephole_optimizations.bitwise_inserts.**SimplifyBitwiseInserts**

Bases: *PeepholeOptimizationExprBase*

simplifies _INSERT(A, c, EXTRACT(A, ...) | B) => A | B

**NAME = 'Simplify bitwise inserts'**

**expr_classes = (<class 'angr.ailment.expression.Insert'>,)**

**optimize**(*expr*, ***kwargs*)

### angr.analyses.decompiler.peephole_optimizations.bitwise_or_to_logical_or

**class** angr.analyses.decompiler.peephole_optimizations.bitwise_or_to_logical_or.**BitwiseOrToLogicalOr**

Bases: *PeepholeOptimizationExprBase*

Perform the following two simplifications:

1. (a | b) == 0 ==> (a == 0) && (b == 0)
2. (a | b) != 0 ==> (a != 0) || (b != 0)

**NAME = '(a | b) == 0 => (a == 0) && (b == 0) ; (a | b) != 0 => (a != 0) || (b != 0)'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.bool_expr_xor_1

class angr.analyses.decompiler.peephole_optimizations.bool_expr_xor_1.**BoolExprXor1**

Bases: *PeepholeOptimizationExprBase*

**NAME = 'bool_expr ^ 1 => !bool_expr (a)'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.bswap

class angr.analyses.decompiler.peephole_optimizations.bswap.**Bswap**

Bases: *PeepholeOptimizationExprBase*

**NAME = 'Simplifying bswap_16(), bswap_32(), and bswap_64()'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>, <class 'angr.ailment.expression.Convert'>)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.bt_rflags_merge

class angr.analyses.decompiler.peephole_optimizations.bt_rflags_merge.**BTRflagsMergeBitExtraction**

Bases: *PeepholeOptimizationExprBase*

Fold CF extractions from the flags merge that the libVEX 3.27+ amd64 BT/BTS/BTR/BTC lifting emits.

The new lifting preserves O/S/A/P/Z across BT-family instructions by writing `(amd64g_calculate_rflags_all(...) & 0x8D4) | bt_bit` into the flags thunk. A downstream condition that tests the tested bit (CF, bit 0) extracts it as `(merge & 0x8D4 | bt_bit) & 1`; since 0x8D4 has bit 0 cleared, this is just `bt_bit`, and folding it lets the (otherwise unreducible) rflags_all ccall become dead.

**NAME = '(x & 0x8d4 | bit) & 1 => bit'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.cas_intrinsics

angr.analyses.decompiler.peephole_optimizations.cas_intrinsics.**cas_intrinsic_name**(*mnemonic*, *os_name*)

Resolve the intrinsic name for a lock-prefixed instruction on the given OS, falling back to Linux naming.

**Return type**
str

**Parameters**

- **mnemonic** (*str*)
- **os_name** (*str | None*)

**class** angr.analyses.decompiler.peephole_optimizations.cas_intrinsics.**CASIntrinsics**

Bases: *PeepholeOptimizationMultiStmtBase*

Rewrite lock-prefixed instructions (or rather, their VEX/AIL forms) into intrinsic calls.

Case 1:

```
             mov eax, r12d
0x140014b57: xchg eax, [0x14000365f8]

LABEL_0x140014b57:
CAS(0x1400365f8<64>, Conv(64->32, vvar_365{reg 112}), Load(addr=0x1400365f8<64>,␣
↪size=4, endness=Iend_LE),
    vvar_27756)
if (CasCmpNE(vvar_27756, g_1400365f8))
    goto LABEL_0x140014b57;

=> vvar_27756 = _InterlockedExchange(0x1400365f8, vvar_365{reg 112})
```

Case 2:

```
lock cmpxchg cs:g_WarbirdSecureFunctionsLock, r14d

CAS(0x1400365f8<64>, 0x1<32>, 0x0<32>, vvar_27751)

=> var_27751 = _InterlockedCompareExchange(0x1400365f8, 0x1<32>, 0x0<32>)
```

**NAME = 'Rewrite compare-and-swap instructions into intrinsics.'**

**stmt_classes = ((<class 'angr.ailment.statement.CAS'>, <class 'angr.ailment.statement.ConditionalJump'>), (<class 'angr.ailment.statement.CAS'>, <class 'angr.ailment.statement.Statement'>))**

**optimize**(*stmts*, *stmt_idx=None*, *block=None*, ***kwargs*)

**Parameters**

- **stmts** (*list[Statement]*)
- **stmt_idx** (*int | None*)

## angr.analyses.decompiler.peephole_optimizations.cmp_masked_shift

**class** angr.analyses.decompiler.peephole_optimizations.cmp_masked_shift.**CmpMaskedShift**

Bases: *PeepholeOptimizationExprBase*

Rewrite an equality comparison against a right-shifted value back into a masked comparison, which reads better for flag/discriminant checks.

(x >> n) == c ==> (x & mask) == (c << n) Convert(N->M, x >> n) == c ==> (x & mask) == (c << n)

where `mask` selects the compared bits `[n, n+width-1]` of `x` and `width` is the truncated width `M` (or `N - n` when there is no Convert). This is the inverse of a simplification that can turn `(x & high_mask) == c` (a mask

that clears the low bits) into the shift/extract form: the masked compare is the clearer form in decompiled output, so restore it.

As a special case, when the compared bits are *all* bits above `n` and the constant is 0, the comparison is an unsigned bound check (libVEX 3.27+ spechelpers fold `x <=u 2**n-1` into this form), so emit the bound check instead:

(x >> n) == 0 ==> x <=u 2**n - 1 (x >> n) != 0 ==> x >u 2**n - 1

Only logical right shifts and unsigned truncations are handled, and only `n > 0` (a low-mask compare, `n == 0`, already reads as a cast).

**NAME = '(x >> n) == c => (x & mask) == (c << n)'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.cmp_sub_const

**class** angr.analyses.decompiler.peephole_optimizations.cmp_sub_const.**CmpSubConst**

Bases: *PeepholeOptimizationExprBase*

Canonicalize equality/inequality comparisons against a constant where one side is a constant add/subtract, by folding the inner constant into the compared constant. This undoes the compiler's strength-reduced `sub`/`dec`-cascade lowering of switch-on-value statements, turning relative constants back into absolute ones:

```
(A - C1) == C2      ==>  A == (C1 + C2)
(A - C1) != C2      ==>  A != (C1 + C2)
(C1 - A) == C2      ==>  A == (C1 - C2)
(A + C1) == C2      ==>  A == (C2 - C1)
```

Note that this rule is only applied to `CmpEQ`/`CmpNE`. Over the modular integers `Z/2^n`, `A - C1 == C2` iff `A == C1 + C2` and `A + C1 == C2` iff `A == C2 - C1` hold unconditionally, independent of signedness and regardless of any intermediate overflow. This rule is NOT applied to ordered comparisons (e.g., `CmpLT`), for which folding across a subtract is unsound because of wraparound.

**NAME = '(A - C1) cmp C2 => A cmp (C1 + C2)'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.cmpf_flag_tests

**class** angr.analyses.decompiler.peephole_optimizations.cmpf_flag_tests.**CmpFFlagTests**

Bases: *PeepholeOptimizationExprBase*

Rewrite condition-flag tests on a `CmpF` result (e.g. `(CmpF(a, b) & 69 | (CmpF(a, b) & 69) >> 6) & 1 == 1` after x86 `ucomisd`) into float comparisons, by evaluating the test for each of the four `CmpF` outcomes.

**NAME = 'Rewrite flag tests on CmpF into float comparisons'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>, <class 'angr.ailment.expression.Convert'>)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp | Convert)

### angr.analyses.decompiler.peephole_optimizations.cmpord_rewriter

**class** angr.analyses.decompiler.peephole_optimizations.cmpord_rewriter.**CmpORDRewriter**

Bases: *PeepholeOptimizationStmtBase*

Rewrites CmpORD expressions (PowerPC and VEX-specific) into common comparison operations.

**NAME = 'CmpORD rewriter'**

**stmt_classes = (<class 'angr.ailment.statement.ConditionalJump'>,)**

**optimize**(*stmt*, *stmt_idx*, *block*, ***kwargs*)

**Parameters**

- **stmt** (ConditionalJump)
- **stmt_idx** (*int*)
- **block** (*Block*)

### angr.analyses.decompiler.peephole_optimizations.coalesce_adjacent_shrs

**class** angr.analyses.decompiler.peephole_optimizations.coalesce_adjacent_shrs.**CoalesceAdjacentShiftRights**

Bases: *PeepholeOptimizationExprBase*

Coalesce adjacent SHR/SAR operations if possible.

**NAME = 'Coalesce adjacent shr/sars'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.coalesce_same_cascading_ifs

**class** angr.analyses.decompiler.peephole_optimizations.coalesce_same_cascading_ifs.**CoalesceSameCascadingIfs**

Bases: *PeepholeOptimizationStmtBase*

**NAME = 'Coalescing cascading If constructs'**

**stmt_classes = (<class 'angr.ailment.statement.ConditionalJump'>,)**

**optimize**(*stmt*, *stmt_idx*, *block*, ***kwargs*)

**Parameters**

- **stmt** (ConditionalJump)
- **stmt_idx** (*int*)
- **block** (*Block*)

### angr.analyses.decompiler.peephole_optimizations.concat_simplifier

**class** angr.analyses.decompiler.peephole_optimizations.concat_simplifier.**ConcatSimplifier**

Bases: *PeepholeOptimizationExprBase*

Simplify Concat expressions: - (a CONCAT b) >> bits(b) => a (high-part extraction) - (a CONCAT b) & mask => b (low-part extraction, where mask = (1 << bits(b)) - 1) - (a >> (bits-1)) CONCAT a => Convert(a, signed, 2*bits) (sign-extension) - 0 CONCAT a => Convert(a, unsigned, 2*bits) (zero-extension) - Convert(a CONCAT b, to_bits=bits(b)) => b (truncate to low part)

**NAME = 'Simplify Concat expressions'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>, <class 'angr.ailment.expression.Convert'>)**

**optimize**(*expr*, *stmt_idx=None*, *block=None*, ***kwargs*)

**Parameters**

- **expr** (BinaryOp | Convert)
- **stmt_idx** (*int* | *None*)

### angr.analyses.decompiler.peephole_optimizations.constant_derefs

**class** angr.analyses.decompiler.peephole_optimizations.constant_derefs.**ConstantDereferences**

Bases: *PeepholeOptimizationExprBase*

Dereferences constant memory loads from read-only memory regions.

**NAME = 'Dereference constant references'**

**expr_classes = (<class 'angr.ailment.expression.Load'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (Load)

### angr.analyses.decompiler.peephole_optimizations.conv_a_sub0_shr_and

**class** angr.analyses.decompiler.peephole_optimizations.conv_a_sub0_shr_and.**ConvASub0ShrAnd**

Bases: *PeepholeOptimizationExprBase*

**NAME = 'Conv(M->1, (expr >> N) & 1) => expr < 0'**

**expr_classes = (<class 'angr.ailment.expression.Convert'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (Convert)

### angr.analyses.decompiler.peephole_optimizations.conv_shl_shr

**class** angr.analyses.decompiler.peephole_optimizations.conv_shl_shr.**ConvShlShr**

Bases: *PeepholeOptimizationExprBase*

**NAME = '(expr << P) >> Q => (expr & mask) >> R'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.eager_eval

**class** angr.analyses.decompiler.peephole_optimizations.eager_eval.**EagerEvaluation**

Bases: *PeepholeOptimizationExprBase*

Eagerly evaluates certain types of expressions.

**NAME = 'Eager expression evaluation'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>, <class 'angr.ailment.expression.UnaryOp'>, <class 'angr.ailment.expression.Convert'>, <class 'angr.ailment.expression.ITE'>)**

**optimize**(*expr*, ***kwargs*)

### angr.analyses.decompiler.peephole_optimizations.evaluate_const_conversions

**class** angr.analyses.decompiler.peephole_optimizations.evaluate_const_conversions.**EvaluateConstConversions**

Bases: *PeepholeOptimizationExprBase*

If we see a conversion over a constant, simply evaluate it

**DESCRIPTION = "Conv(*, C) => C'"**

**expr_classes = (<class 'angr.ailment.expression.Convert'>, <class 'angr.ailment.expression.Extract'>)**

**optimize**(*expr*, ***, *stmt_idx=None*, *block=None*, ***kwargs*)

**Parameters**
**stmt_idx** (*int | None*)

**fixpoint_reached: bool**

**func_addr: int | None**

**kb: *KnowledgeBase* | None**

**manager**

**preserve_vvar_ids:** set[int]

**project:** *Project* | None

**type_hints:** list[tuple[*VirtualVariable* | *MemoryLocation*, str]]

### angr.analyses.decompiler.peephole_optimizations.extended_byte_and_mask

**class** angr.analyses.decompiler.peephole_optimizations.extended_byte_and_mask.**ExtendedByteAndMask**

Bases: *PeepholeOptimizationExprBase*

**NAME = 'extended byte & 0xff..ff => extended byte'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.float_const_bits

**class** angr.analyses.decompiler.peephole_optimizations.float_const_bits.**FloatConstBits**

Bases: *PeepholeOptimizationExprBase*

A floating-point constant under a bitwise operation or an integer widening is its bit pattern: a sign mask loaded into an FP register (`movsd xmm1, [-0.0]; xorpd xmm0, xmm1`) is `0x8000000000000000`, not `-0.0`.

**NAME = 'Replace floating-point constants under bitwise operations with their bit patterns'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>, <class 'angr.ailment.expression.Convert'>)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp | Convert)

### angr.analyses.decompiler.peephole_optimizations.fp_exact_identities

**class** angr.analyses.decompiler.peephole_optimizations.fp_exact_identities.**FPExactIdentities**

Bases: *PeepholeOptimizationExprBase*

Floating-point simplifications that are value-exact (bit for bit, for every input):

- `x * 1.0` and `1.0 * x` -> `x`: exact for every x, including ±0, ±inf and NaN, in any rounding mode.
- `(Exp2(y) - 1.0) + 1.0` -> `Exp2(y)`: x87 `f2xm1; fld1; faddp`. `Exp2` comes only from f2xm1, which the converter lowers to `Exp2(y) - 1.0`; f2xm1 is defined only for y in [-1, 1], so e = exp2(y) lies in [0.5, 2]. By Sterbenz's lemma e - 1.0 is then exact, and (e - 1.0) + 1.0 = e is representable, so the add is exact as well: the folded expression has the same value as the unfolded one in the operation's type. (The hardware rounds 2^y - 1 to extended precision before adding 1, so either C form may differ from the machine result in the last bit; the fold does not change that.)

Not folded, since they are not exact: `(x - 1.0) + 1.0` for arbitrary x (absorbs tiny x, rounds huge x), and `-(a - b)` -> `b - a` (a == b gives -0.0 vs +0.0).

**NAME = 'Fold value-exact floating-point identities'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.inlined_strcpy

### angr.analyses.decompiler.peephole_optimizations.inlined_strcpy_consolidation

### angr.analyses.decompiler.peephole_optimizations.invert_negated_logical_conjuction_disjunction

**class** angr.analyses.decompiler.peephole_optimizations.invert_negated_logical_conjuction_disjunction.**InvertNegatedLogicalConjunctionsAndDisjunctions**

Bases: *PeepholeOptimizationExprBase*

Push negations into subexpressions of logical conjunctions and logical disjunctions.

**NAME = '!(A && B) => A || B; !(A || B) => A && B'**

**expr_classes = (<class 'angr.ailment.expression.UnaryOp'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (UnaryOp)

### angr.analyses.decompiler.peephole_optimizations.known_pattern_call_info

**class** angr.analyses.decompiler.peephole_optimizations.known_pattern_call_info.**KnownPatternCallInfo**

Bases: *PeepholeOptimizationExprBase*

Attach call-site prototypes (and optional vvar type hints) to calls that were synthesized from KnownPatterns (see angr.analyses.decompiler.known_patterns).

Known-pattern calls are identified by their string target, which is stable across Clinic runs, while the VariableMap holding prototypes is scoped to a single Clinic run; running as a peephole re-applies the prototype in every run so that variable recovery emits per-argument type constraints for Typehoon (e.g. `arg <:  std::string *` for std::string::length).

**NAME = 'Attach prototypes and type hints to known-pattern calls'**

**expr_classes = (<class 'angr.ailment.expression.Call'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (Call)

### angr.analyses.decompiler.peephole_optimizations.magic_div_simplifier

**class** angr.analyses.decompiler.peephole_optimizations.magic_div_simplifier.**MagicDivisionSimplifier**

Bases: *PeepholeOptimizationExprBase*

Restore divisions by constants that compilers lower into shifts and multiply-high sequences:

- `(x + ((x >>a (n-1)) >> (n-k))) >>a k` and `(x + (x >> (n-1))) >>a 1 => x /s 2**k`
- `x - ((x + <same bias>) & -2**k) => x %s 2**k`
- `((x + hi(x * M)) >>a s) - (x >>a (n-1))` and `(hi(x * M) >>a s) - (x >>a (n-1)) => x /s d`
- `hi(x * M) >> s => x /u d`

where `hi(x * M)` is the upper half of a double-width product. Each candidate divisor is checked by evaluating the matched sequence on sample inputs.

**NAME = 'Simplify divisions by constants lowered to shifts and multiply-high'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>, <class 'angr.ailment.expression.Convert'>)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp | Convert)

### angr.analyses.decompiler.peephole_optimizations.masked_insert

**class** angr.analyses.decompiler.peephole_optimizations.masked_insert.**SimplifyMaskedInsert**

Bases: *PeepholeOptimizationExprBase*

Reads of an Insert that only see the inserted value or only see the base:

**Insert(base, off, v) & mask ==> (Conv(v) << off*8) & mask when mask only covers v's bits**
==> base & mask when mask covers none of v's bits

Extract(Insert(base, off, v), ...) and Conv(Insert(base, off, v)) (truncation) likewise.

Masks of nested `& c` chains are combined, e.g. `Insert(x, 0, b) & 0xffff & 15` reads only b.

**NAME = 'Simplify masked reads of Insert'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>, <class 'angr.ailment.expression.Extract'>, <class 'angr.ailment.expression.Convert'>)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp | Extract | Convert)

### angr.analyses.decompiler.peephole_optimizations.modulo_simplifier

**class** angr.analyses.decompiler.peephole_optimizations.modulo_simplifier.**ModuloSimplifier**

Bases: *PeepholeOptimizationExprBase*

Simplify division and multiplication expressions that can be reduced to a modulo operation.

**NAME = 'a - (a / N) * N => a % N'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)**

**optimize**(*expr*, *stmt_idx=None*, *block=None*, ***kwargs*)

**Parameters**

- **expr** (BinaryOp)
- **stmt_idx** (*int | None*)

### angr.analyses.decompiler.peephole_optimizations.narrow_fp_ops

**class** angr.analyses.decompiler.peephole_optimizations.narrow_fp_ops.**NarrowFPOperations**

Bases: *PeepholeOptimizationExprBase*

Narrow floating-point operations when all FP operands are VEX FP promotions from the same source width.

VEX emulates x87 with F64, so float operations appear as:

```
AddF64(Conv(32F->64F, a), Conv(32F->64F, b))
```

Since both operands are 32-bit floats promoted for emulation, the operation is semantically 32-bit. Narrow to:

```
Conv(32F->64F, AddF32(a, b))
```

The conversion keeps the width the parent expression was built with. A parent whose other operand is also a promotion is narrowed in turn.

**NAME = 'Narrow FP operations with promoted float operands'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.one_sub_bool

**class** angr.analyses.decompiler.peephole_optimizations.one_sub_bool.**OneSubBool**

Bases: *PeepholeOptimizationExprBase*

**NAME = '1 - bool_expr => !bool_expr'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.optimized_div_simplifier

**class** angr.analyses.decompiler.peephole_optimizations.optimized_div_simplifier.**OptimizedDivisionSimplifier**

Bases: *PeepholeOptimizationExprBase*

Convert expressions with right shifts into expressions with divisions.

NAME = 'Simplify optimized division expressions, e.g., (N * a) >> M => a / N1'

expr_classes = (<class 'angr.ailment.expression.Convert'>, <class 'angr.ailment.expression.BinaryOp'>)

optimize(*expr*, *stmt_idx=None*, *block=None*, ***kwargs*)

**Parameters**

- **expr** (Convert | BinaryOp)
- **stmt_idx** (*int* | *None*)

optimize_binaryop(*original_expr*)

**Parameters**
**original_expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.recombine_split_halves

class angr.analyses.decompiler.peephole_optimizations.recombine_split_halves.RecombineSplitHalves

Bases: *PeepholeOptimizationExprBase*

(a & (2 ** N - 1)) | ((a >> N) << N) => a

A value split into register halves (e.g., rdtsc's edx:eax) and put back together. The left shift may already be rewritten into a multiplication, and the low half may be a pair of truncating and extending conversions.

NAME = '(a & mask) | ((a >> N) << N) => a'

expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)

optimize(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.remove_cascading_conversions

class angr.analyses.decompiler.peephole_optimizations.remove_cascading_conversions.RemoveCascadingConversions

Bases: *PeepholeOptimizationExprBase*

NAME = 'Simplify adjacent size conversions'

expr_classes = (<class 'angr.ailment.expression.Convert'>,)

optimize(*expr*, ***kwargs*)

**Parameters**
**expr** (Convert)

### angr.analyses.decompiler.peephole_optimizations.remove_const_insert

class angr.analyses.decompiler.peephole_optimizations.remove_const_insert.RemoveConstInsert

Bases: *PeepholeOptimizationExprBase*

NAME = 'Insert(c0, c1, v) ==> (c0 & mask) | (v << c1)'

expr_classes = (<class 'angr.ailment.expression.Insert'>,)

optimize(*expr*, ***kwargs*)

**Parameters**
**expr** (Insert)

### angr.analyses.decompiler.peephole_optimizations.remove_cxx_destructor_calls

class angr.analyses.decompiler.peephole_optimizations.remove_cxx_destructor_calls.RemoveCxxDestructorCalls

Bases: *PeepholeOptimizationStmtBase*

Rewrite C++ operator function calls into operations.

NAME = 'Remove C++ destructor function calls'

stmt_classes = (<class 'angr.ailment.statement.SideEffectStatement'>,)

optimize(*stmt*, ***kwargs*)

**Return type**
tuple | None

**Parameters**
**stmt** (SideEffectStatement)

### angr.analyses.decompiler.peephole_optimizations.remove_empty_if_body

class angr.analyses.decompiler.peephole_optimizations.remove_empty_if_body.RemoveEmptyIfBody

Bases: *PeepholeOptimizationStmtBase*

NAME = 'Remove empty If bodies'

stmt_classes = (<class 'angr.ailment.statement.ConditionalJump'>,)

optimize(*stmt*, *stmt_idx*, *block*, ***kwargs*)

**Parameters**

- **stmt** (ConditionalJump)
- **stmt_idx** (*int*)
- **block** (*Block*)

### angr.analyses.decompiler.peephole_optimizations.remove_fptag_nan_ite

class angr.analyses.decompiler.peephole_optimizations.remove_fptag_nan_ite.RemoveFptagNanITE

Bases: *PeepholeOptimizationExprBase*

**VEX x87 lifting wraps FP register accesses in fptag validity checks:**
ITE(fptag != 0, fp_value, empty) – for reads (valid -> value, empty -> NaN/0 placeholder) ITE(fptag != 0, empty, fp_value) – for pushes

Since decompiled code assumes FP registers are valid, strip these ITEs and keep the real (non-placeholder) branch. The placeholder is a NaN constant, or – before later simplification turns it into a NaN – a zero constant guarded by a condition that reads the x87 fptag register.

**NAME = 'Remove fptag NaN ITE checks'**

**expr_classes = (<class 'angr.ailment.expression.ITE'>,)**

**optimize**(*expr*, *, *block=None*, *block_defs=None*, ***kwargs*)

**Parameters**

- **expr** (ITE)
- **block_defs** (BlockDefs | *None*)

### angr.analyses.decompiler.peephole_optimizations.remove_int_fp_int_roundtrip

**class** angr.analyses.decompiler.peephole_optimizations.remove_int_fp_int_roundtrip.**RemoveIntFPIntRoundTrip**

Bases: *PeepholeOptimizationExprBase*

Conv(F->sN, Conv(sN->F, x)) ==> x when the int -> FP conversion is exact.

That is the case when the FP significand holds every N-bit integer, and also for 64-bit integers on 32-bit x86: there, I64StoF64 only comes from x87 `fild` (SSE cannot convert 64-bit integers outside of 64-bit mode), which loads into the 80-bit format whose 64-bit significand holds any int64 (precision control does not apply to loads). VEX models the x87 registers as F64 regardless. `fistp` of an integral value is exact in every rounding mode, so the pair is a plain int64 copy, which compilers use to move 8 bytes at once.

**NAME = 'Remove int -> FP -> int round trips'**

**expr_classes = (<class 'angr.ailment.expression.Convert'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**

**expr** (Convert)

### angr.analyses.decompiler.peephole_optimizations.remove_noop_conversions

**class** angr.analyses.decompiler.peephole_optimizations.remove_noop_conversions.**RemoveNoopConversions**

Bases: *PeepholeOptimizationExprBase*

**NAME = 'Remove no-op conversions'**

**expr_classes = (<class 'angr.ailment.expression.Convert'>, <class 'angr.ailment.expression.Extract'>)**

**optimize**(*expr*, ***kwargs*)

**Parameters**

**expr** (Convert | Extract)

### angr.analyses.decompiler.peephole_optimizations.remove_redundant_bitmasks

**class** angr.analyses.decompiler.peephole_optimizations.remove_redundant_bitmasks.**RemoveRedundantBitmasks**

Bases: *PeepholeOptimizationExprBase*

Remove redundant bitmasking operations.

**NAME = 'Remove redundant bitmasks'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>, <class 'angr.ailment.expression.Convert'>, <class 'angr.ailment.expression.Extract'>, <class 'angr.ailment.expression.Insert'>)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp | Convert | Extract | Insert)

### angr.analyses.decompiler.peephole_optimizations.remove_redundant_conversions

**class** angr.analyses.decompiler.peephole_optimizations.remove_redundant_conversions.**RemoveRedundantConversions**

Bases: *PeepholeOptimizationExprBase*

**NAME = 'Remove or rewrite redundant conversions around binary operators'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>, <class 'angr.ailment.expression.Convert'>)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp | Convert)

### angr.analyses.decompiler.peephole_optimizations.remove_redundant_derefs

**class** angr.analyses.decompiler.peephole_optimizations.remove_redundant_derefs.**RemoveRedundantDerefs**

Bases: *PeepholeOptimizationExprBase*

Remove redundant dereferences (e.g. `*(&v)`).

**NAME = 'Remove redundant dereferences'**

**expr_classes = (<class 'angr.ailment.expression.Load'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (Load)

### angr.analyses.decompiler.peephole_optimizations.remove_redundant_insert

**class** angr.analyses.decompiler.peephole_optimizations.remove_redundant_insert.**RemoveRedundantInsert**

Bases: *PeepholeOptimizationExprBase*

NAME = 'Remove redundant INSERT operators'

expr_classes = (<class 'angr.ailment.expression.Insert'>,)

optimize(*expr*, ***kwargs*)

**Parameters**
**expr** (Insert)

### angr.analyses.decompiler.peephole_optimizations.remove_redundant_ite_branch

class angr.analyses.decompiler.peephole_optimizations.remove_redundant_ite_branch.**RemoveRedundantITEBranches**

Bases: *PeepholeOptimizationExprBase*

NAME = 'Remove redundant ITE branches'

expr_classes = (<class 'angr.ailment.expression.ITE'>,)

optimize(*expr*, ***kwargs*)

**Parameters**
**expr** (ITE)

### angr.analyses.decompiler.peephole_optimizations.remove_redundant_ite_comparisons

class angr.analyses.decompiler.peephole_optimizations.remove_redundant_ite_comparisons.**RemoveRedundantITEComparisons**

Bases: *PeepholeOptimizationExprBase*

Remove redundant ITE comparisons.

NAME = 'Remove redundant ITE comparisons'

expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)

optimize(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.remove_redundant_nots

class angr.analyses.decompiler.peephole_optimizations.remove_redundant_nots.**RemoveRedundantNots**

Bases: *PeepholeOptimizationExprBase*

NAME = 'Remove redundant Nots'

expr_classes = (<class 'angr.ailment.expression.UnaryOp'>,)

optimize(*expr*, ***kwargs*)

**Parameters**
**expr** (UnaryOp)

### angr.analyses.decompiler.peephole_optimizations.remove_redundant_reinterprets

**class** angr.analyses.decompiler.peephole_optimizations.remove_redundant_reinterprets.**RemoveRedundantReinterprets**

Bases: *PeepholeOptimizationExprBase*

Simplify Reinterpret() expressions: nested and constant ones, the integer view VEX puts between a floating-point register and memory (`Reinterpret(I->F, Load)`: memory is untyped, the load carries the float), and a view whose consumer expects the original type (an integer operation on `Reinterpret(I->F, x)` operates on `x`).

**NAME = 'Simplifying nested, constant, and type-consistent Reinterprets'**

**expr_classes = (<class 'angr.ailment.expression.Reinterpret'>, <class 'angr.ailment.expression.BinaryOp'>, <class 'angr.ailment.expression.UnaryOp'>, <class 'angr.ailment.expression.Convert'>)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (Reinterpret | BinaryOp | UnaryOp | Convert)

### angr.analyses.decompiler.peephole_optimizations.remove_redundant_shifts

**class** angr.analyses.decompiler.peephole_optimizations.remove_redundant_shifts.**RemoveRedundantShifts**

Bases: *PeepholeOptimizationExprBase*

Remove redundant bitshift operations.

**NAME = 'Remove redundant bitshifts'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.remove_redundant_shifts_around_comparators

**class** angr.analyses.decompiler.peephole_optimizations.remove_redundant_shifts_around_comparators.**RemoveRedundantShiftsAroundComparators**

Bases: *PeepholeOptimizationExprBase*

Remove redundant bitshifts for both operands around a comparison operator.

More cases can be added in the future as we encounter them.

**NAME = 'Remove redundant bitshifts for operands around a comparator'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)**

**optimize**(*expr*, *stmt_idx=None*, *block=None*, ***kwargs*)

**Parameters**

- **expr** (BinaryOp)
- **stmt_idx** (*int* | *None*)

### angr.analyses.decompiler.peephole_optimizations.remove_reinterprets_at_stores

**class** angr.analyses.decompiler.peephole_optimizations.remove_reinterprets_at_stores.**RemoveReinterpretsAtStores**

Bases: *PeepholeOptimizationStmtBase*

Drop the integer view that VEX puts between a floating-point register and memory: `Store(Reinterpret(F->I, x))` stores the float itself (memory is untyped).

**NAME = 'Remove Reinterprets at stores'**

**stmt_classes = (<class 'angr.ailment.statement.Store'>,)**

**optimize**(*stmt*, *stmt_idx*, *block*, ***kwargs*)

**Parameters**

- **stmt** (*Store*)
- **stmt_idx** (*int*)
- **block** (*Block*)

### angr.analyses.decompiler.peephole_optimizations.rewrite_bit_extractions

**class** angr.analyses.decompiler.peephole_optimizations.rewrite_bit_extractions.**RewriteBitExtractions**

Bases: *PeepholeOptimizationExprBase*

Rewrite bit extraction expressions

**NAME = 'Bit-extraction Rewriter'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**

**expr** (*BinaryOp*)

### angr.analyses.decompiler.peephole_optimizations.rewrite_conv_mul

**class** angr.analyses.decompiler.peephole_optimizations.rewrite_conv_mul.**RewriteConvMul**

Bases: *PeepholeOptimizationExprBase*

Rewrites multiplication to be inside conversion.

**NAME = 'Rewrite Conv Mul'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**

**expr** (*BinaryOp*)

### angr.analyses.decompiler.peephole_optimizations.rewrite_cxx_operator_calls

**class** angr.analyses.decompiler.peephole_optimizations.rewrite_cxx_operator_calls.**RewriteCxxOperatorCalls**

Bases: *PeepholeOptimizationStmtBase*

Rewrite C++ operator function calls into operations.

**NAME = 'Rewrite C++ operator function calls into operations'**

**stmt_classes = (<class 'angr.ailment.statement.SideEffectStatement'>, <class 'angr.ailment.statement.WeakAssignment'>)**

**optimize**(*stmt*, *block=None*, ***kwargs*)

**Parameters**
**stmt** (SideEffectStatement | WeakAssignment)

### angr.analyses.decompiler.peephole_optimizations.rewrite_mips_gp_loads

**class** angr.analyses.decompiler.peephole_optimizations.rewrite_mips_gp_loads.**RewriteMipsGpLoads**

Bases: *PeepholeOptimizationExprBase*

Rewrite $gp-based loads to their actual values on MIPS.

**NAME = 'MIPS GP-based Loads Rewriter'**

**expr_classes = (<class 'angr.ailment.expression.Load'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (Load)

### angr.analyses.decompiler.peephole_optimizations.rol_ror

**class** angr.analyses.decompiler.peephole_optimizations.rol_ror.**RolRorRewriter**

Bases: *PeepholeOptimizationStmtBase*

Rewrites consecutive statements into ROL (rotate shift left) or ROR (rotate shift right) statements.

**NAME = 'ROL/ROR rewriter'**

**stmt_classes = (<class 'angr.ailment.statement.Assignment'>,)**

**optimize**(*stmt*, *stmt_idx*, *block*, ***kwargs*)

**Parameters**

- **stmt** (Assignment)
- **stmt_idx** (*int*)
- **block** (*Block*)

### angr.analyses.decompiler.peephole_optimizations.sar_to_signed_div

**class** angr.analyses.decompiler.peephole_optimizations.sar_to_signed_div.**SarToSignedDiv**

Bases: *PeepholeOptimizationExprBase*

Simplify signed divisions that are optimized into bit shifts during compilation.

**NAME = '(signed(expr)? expr + A ** 2 - 1:  expr) >>s A => expr /s 2 ** A'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)**

**optimize**(*expr*, *stmt_idx=None*, *block=None*, ***kwargs*)

**Parameters**

- **expr** (BinaryOp)
- **stmt_idx** (*int | None*)

### angr.analyses.decompiler.peephole_optimizations.sbb_mask_to_ite

**class** angr.analyses.decompiler.peephole_optimizations.sbb_mask_to_ite.**SbbMaskToITE**

Bases: *PeepholeOptimizationExprBase*

Turn the branchless select built from a carry (cmp x, 1; sbb eax, eax; and eax, K; sub eax, D) into an ITE:

(-Conv(1->N, c)) & K ==> ITE(c, K, 0) ITE(c, K0, K1) +/- D ==> ITE(c, K0 +/- D, K1 +/- D) b <u 1 (b is 1-bit) ==> !b ITE(!c, a, b) ==> ITE(c, b, a)

**NAME = 'Branchless carry-mask select to ITE'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>, <class 'angr.ailment.expression.ITE'>)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp | ITE)

### angr.analyses.decompiler.peephole_optimizations.shl_to_mul

**class** angr.analyses.decompiler.peephole_optimizations.shl_to_mul.**ShlToMul**

Bases: *PeepholeOptimizationExprBase*

**NAME = 'a << A => a * (2 ** A)'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.sign_bit_test

**class** angr.analyses.decompiler.peephole_optimizations.sign_bit_test.**SignBitTest**

Bases: *PeepholeOptimizationExprBase*

`((x >> (n-1)) & 1) != 0` and `(x >> (n-1)) == 1` => `x <s 0`; the negated forms become `x >=s 0`.

NAME = '(x >> (n-1)) & 1 != 0 => x < 0'

expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)

optimize(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.simplify_pc_relative_loads

class angr.analyses.decompiler.peephole_optimizations.simplify_pc_relative_loads.SimplifyPcRelativeLoads

Bases: *PeepholeOptimizationExprBase*

Simplifying pc-relative loads.

NAME = 'Simplify PC-relative loads'

expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)

optimize(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.single_bit_cond_to_boolexpr

class angr.analyses.decompiler.peephole_optimizations.single_bit_cond_to_boolexpr.SingleBitCondToBoolExpr

Bases: *PeepholeOptimizationExprBase*

Convert single-bit conditions to bool expressions

NAME = 'Convert single-bit conditions to bool expressions (== 0 or == 1)'

expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)

optimize(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.single_bit_xor

class angr.analyses.decompiler.peephole_optimizations.single_bit_xor.SingleBitXor

Bases: *PeepholeOptimizationExprBase*

NAME = 'bool_expr ^ 1 => !bool_expr (b)'

expr_classes = (<class 'angr.ailment.expression.Convert'>,)

optimize(*expr*, ***kwargs*)

**Parameters**
**expr** (Convert)

### angr.analyses.decompiler.peephole_optimizations.sse_bitwise_select

Simplify SSE bitwise conditional select patterns to ITE expressions.

SSE branchless conditional moves use:

mask = CmpLTV(0, x) ^ 0xFFFF... (or ~CmpLTV) result = (~mask & A) | (B & mask)

This is equivalent to: (condition) ? B : A

This peephole recognizes the pattern and collapses it to an ITE.

**class** angr.analyses.decompiler.peephole_optimizations.sse_bitwise_select.**SSEBitwiseSelect**

Bases: *PeepholeOptimizationExprBase*

Collapse SSE bitwise select (andnpd/andpd/orpd) into ITE.

**NAME = 'SSE bitwise select to ITE'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>, <class 'angr.ailment.expression.Extract'>)**

**optimize**(*expr*, *, *block=None*, ***kwargs*)

**Parameters**
**expr** (BinaryOp | Extract)

### angr.analyses.decompiler.peephole_optimizations.sse_movemask

SSE/AVX sign-mask extraction (movmskpd / movmskps / vmovmskpd / vmovmskps).

VEX lifts `movmskpd eax, xmm0` lane by lane: the sign bit of lane i is shifted into bit i of the result:

```
((Extract(v, 32@4) >> 31) & 1) | ((Extract(v, 32@12) >> 30) & 2)
```

The whole Or-tree becomes `MovMskPD(v)` / `MovMskPS(v)` (rendered as `_mm_movemask_pd(v)`, or `signbit(v)` when v is a scalar). When the consumer masks the result down to bit 0, the upper-lane terms drop out and the read becomes `SignBit(lane0(v))`.

**class** angr.analyses.decompiler.peephole_optimizations.sse_movemask.**SSEMoveMask**

Bases: *PeepholeOptimizationExprBase*

Fold the lane-wise sign-bit gathering of movmskpd/movmskps into one op, and reduce bit-0 reads to signbit.

**NAME = 'SSE movmskpd/movmskps to MovMsk/SignBit'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.sse_scalar_lowering

**class** angr.analyses.decompiler.peephole_optimizations.sse_scalar_lowering.**SSEVectorConvertLowering**

Bases: *PeepholeOptimizationExprBase*

Lower a lane-wise conversion of a scalar that was zero-widened into lane 0.

ConvV(Conv(N->128I, x)) -> Conv(M->128I, Convert(N->M, x)); upper lanes stay zero.

**NAME = 'SSE lane-wise conversion of a widened scalar'**

**expr_classes = (<class 'angr.ailment.expression.Convert'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (Convert)

**class**
angr.analyses.decompiler.peephole_optimizations.sse_scalar_lowering.**SSEScalarLowering**

Bases: *PeepholeOptimizationExprBase*

Lower SSE scalar-in-vector ops to scalar floating-point arithmetic.

VEX represents SSE scalar ops (addss, mulss, addsd, ...) as full-width 128-bit vector operations (Add32F0x4, Add64F0x2, ...) followed by a read of the lower element. After AIL lifting and SSAIL propagation this produces:

```
Extract(BinaryOp("XxxV", ..., fp=True), N@0)
```

This pass rewrites such expressions to their scalar equivalents so that type inference, constant folding, and codegen all handle them correctly.

**NAME = 'SSE scalar-in-vector op lowering'**

**expr_classes = (<class 'angr.ailment.expression.Extract'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (Extract)

## angr.analyses.decompiler.peephole_optimizations.sse_vector_lane_lowering

angr.analyses.decompiler.peephole_optimizations.sse_vector_lane_lowering.**lane0**(*expr*, *lane_bits*, *manager*)

The lowest *lane_bits* bits of a vector operand.

**Return type**
*Expression*

**Parameters**

- **expr** (Expression)
- **lane_bits** (*int*)
- **manager** (*Manager*)

angr.analyses.decompiler.peephole_optimizations.sse_vector_lane_lowering.**upper_lanes_zero**(*expr*, *lane_bits*)

True if every lane above lane 0 of *expr* is zero (a movd/movq zero-extension, or a lane-wise op that maps zero lanes to zero lanes).

**Return type**
bool

**Parameters**

- **expr** (Expression)

- **lane_bits** (*int*)

angr.analyses.decompiler.peephole_optimizations.sse_vector_lane_lowering.**lower_lane0**(*expr*, *manager*)

Lane 0 of a lane-wise vector op as a scalar expression of one lane's width, or None.

**Return type**
*Expression* | None

**Parameters**

- **expr** (BinaryOp | Convert)
- **manager** (*Manager*)

**class** angr.analyses.decompiler.peephole_optimizations.sse_vector_lane_lowering.**SSEVectorLaneLowering**

Bases: *PeepholeOptimizationExprBase*

Lower a lane-0 read of a lane-wise vector op to the scalar op on lane 0.

**NAME = 'SSE lane-0 reads of vector ops to scalar ops'**

**expr_classes = (<class 'angr.ailment.expression.Extract'>, <class 'angr.ailment.expression.Convert'>)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (Extract | Convert)

### angr.analyses.decompiler.peephole_optimizations.tidy_stack_addr

**class** angr.analyses.decompiler.peephole_optimizations.tidy_stack_addr.**TidyStackAddr**

Bases: *PeepholeOptimizationExprBase*

Consolidate StackBaseOffset objects and constant offsets within each stack address expression.

**NAME = 'Tidy stack addresses'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (BinaryOp)

### angr.analyses.decompiler.peephole_optimizations.utils

angr.analyses.decompiler.peephole_optimizations.utils.**get_expr_shift_left_amount**(*expr*)

Get the shift amount of a shift-left or multiplication operation if the shift amount is a constant.

**Parameters**
**expr** (*BinaryOp*) – The shift-left or multiplication expression (must be a BinaryOp).

**Return type**
int | None

**Returns**
The shift amount if it is a constant, or None if it is not.

### angr.analyses.decompiler.peephole_optimizations.x87_cmpf

**class** angr.analyses.decompiler.peephole_optimizations.x87_cmpf.**X87CmpF**

Bases: *PeepholeOptimizationExprBase*

Simplifies x87 CmpF status word bit extractions into readable comparison operators.

**x87 CmpF returns a 32-bit status word:**
0x00 = GT, 0x01 = LT, 0x40 = EQ, 0x45 = Unordered

GCC emits bit manipulation patterns to extract the comparison result. This peephole matches those patterns and replaces them with CmpGT, CmpLE, or CmpEQ.

**NAME = 'Simplifying CmpF on x87'**

**expr_classes = (<class 'angr.ailment.expression.BinaryOp'>, <class 'angr.ailment.expression.ITE'>, <class 'angr.ailment.expression.UnaryOp'>)**

**optimize**(*expr*, ***, *stmt_idx=None*, *block=None*, *block_defs=None*, ***kwargs*)

**Parameters**

- **expr** (BinaryOp | ITE | UnaryOp)
- **stmt_idx** (*int* | *None*)
- **block_defs** (BlockDefs | *None*)

### angr.analyses.decompiler.peephole_optimizations.x87_narrowing_store

**class** angr.analyses.decompiler.peephole_optimizations.x87_narrowing_store.**X87NarrowingStore**

Bases: *PeepholeOptimizationStmtBase*

Store(addr, x<80>, size=8) ==> Store(addr, Conv(80F->64F, x), size=8)

VEX models the x87 registers as F64, so a long double loaded with `fld m80` stays 80 bits wide when it is propagated into an `fstp m64`. The store narrows it to double (which may raise overflow/underflow).

**NAME = 'x87:  narrow long double stored as double'**

**stmt_classes = (<class 'angr.ailment.statement.Store'>,)**

**optimize**(*stmt*, *stmt_idx*, *block*, ***kwargs*)

**Parameters**

- **stmt** (Store)
- **stmt_idx** (*int*)
- **block** (*Block*)

### angr.analyses.decompiler.presets

**class** angr.analyses.decompiler.presets.**DecompilationPreset**

Bases: object

A DecompilationPreset provides a preconfigured set of optimizations and configurations for the Decompiler analysis.

__init__(*name*, *opt_passes*)

**Parameters**

- **name** (*str*)
- **opt_passes** (*list[type[BaseOptimizationPass]]*)

get_optimization_passes(*arch*, *platform*, *additional_opts=None*, *disable_opts=None*)

**Parameters**

- **arch** (*Arch | str*)
- **platform** (*str | None*)

### Submodules

| |
|---|
| *basic* |
| *fast* |
| *full* |
| *malware* |
| *preset* |

#### angr.analyses.decompiler.presets.basic

#### angr.analyses.decompiler.presets.fast

#### angr.analyses.decompiler.presets.full

#### angr.analyses.decompiler.presets.malware

#### angr.analyses.decompiler.presets.preset

class angr.analyses.decompiler.presets.preset.**DecompilationPreset**

Bases: object

A DecompilationPreset provides a preconfigured set of optimizations and configurations for the Decompiler analysis.

__init__(*name*, *opt_passes*)

**Parameters**

- **name** (*str*)
- **opt_passes** (*list[type[BaseOptimizationPass]]*)

get_optimization_passes(*arch*, *platform*, *additional_opts=None*, *disable_opts=None*)

**Parameters**

- **arch** (*Arch | str*)
- **platform** (*str | None*)

### angr.analyses.decompiler.redundant_label_remover

**class** angr.analyses.decompiler.redundant_label_remover.**RedundantLabelRemover**

Bases: object

Remove redundant labels.

This optimization pass contains two separate passes. The first pass (self._walker0) finds all redundant labels (e.g., two or more labels for the same location) and records the replacement label for redundant labels in self._new_jump_target. The second pass (self._walker1) removes all redundant labels that (a) are not referenced anywhere (determined by jump_targets), or (b) are deemed replaceable by the first pass.

**__init__**(*node*, *jump_targets*)

**Parameters**

**jump_targets** (*set[tuple[int, int]]*)

### angr.analyses.decompiler.region_identifier

**type** angr.analyses.decompiler.region_identifier.**TNode** = *Tx*[Block | *MultiNode* | *ConditionNode*]

**type** angr.analyses.decompiler.region_identifier.**TOverlay** = *RegionOverlay*[Block | *MultiNode* | *ConditionNode*]

**type** angr.analyses.decompiler.region_identifier.**TManager** = *OverlayManager*[Block | *MultiNode* | *ConditionNode*]

**type** angr.analyses.decompiler.region_identifier.**TGraph** = networkx.DiGraph[*TNode*]

**class** angr.analyses.decompiler.region_identifier.**RegionIdentifier**

Bases: *Analysis*

A region is a single-entry-single-exit subgraph of control flow. The region identifier recursively identifies the smallest possible regions within a function graph and creates a RegionOverlay object whose nodes are either Blocks or RegionOverlays.

Note, that the analysis may modify the graph in-place. If you want to keep the original graph, set the *update_graph* parameter to False.

**__init__**(*func*, *cond_proc=None*, *graph=None*, *ail_manager=None*, *update_graph=True*, *largest_successor_tree_outside_loop=True*, *force_loop_single_exit=True*, *refine_loops_with_single_successor=False*, *expose_loop_head_backedges=False*, *force_single_loop_entry=False*, *entry_node_addr=None*)

**Parameters**

- **func** (Function)
- **cond_proc** (ConditionProcessor | *None*)
- **graph** (*networkx.DiGraph[Block]* | *None*)
- **ail_manager** (*Manager* | *None*)
- **entry_node_addr** (*tuple[int, int]* | *None*)

**test_reducibility**()

**Return type**

bool

### angr.analyses.decompiler.region_overlay

**class** angr.analyses.decompiler.region_overlay.**RegionBound**

Bases: Protocol

The protocol indicating the minimum capabilities of graph nodes to be managed by an overlay region.

**property addr:** int

**__init__**(**args*, ***kwargs*)

**type** angr.analyses.decompiler.region_overlay.**Tx**[*U:* RegionBound]() = **U** | ***RegionOverlay*[U]**

angr.analyses.decompiler.region_overlay.**merge_edge_data**(*acc*, *data*)

Merge the data of two complete-graph edges that are about to be merged. `abnormal_entry` merged with an untagged edge keeps the tag and gains `normal_entry`: The jump into the body still becomes a goto later, but the edge must be kept.

**Return type**
dict[str, Any]

**Parameters**

- **acc** (*dict[str, Any]*)
- **data** (*dict[str, Any]*)

**class** angr.analyses.decompiler.region_overlay.**OverlayManager**

Bases: Generic[T]

OverlayManager owns the single (complete) control-flow graph that all RegionOverlay objects are views of, plus the node-to-innermost-overlay ownership map.

All structural mutations of the complete graph must go through this class (usually via RegionOverlay methods) so that ownership, caches, and the undo log stay consistent.

**__init__**(*graph*, *expose_loop_head_backedges=False*)

**Parameters**

- **graph** (*networkx.DiGraph[T]*)
- **expose_loop_head_backedges** (*bool*)

**graph**

**expose_loop_head_backedges**

**root**

**property version:** int

**owner_of**(*node*)

**Return type**
Optional[*RegionOverlay*[T]]

**Parameters**
**node** (*Tx[T]*)

**checkpoint**()

**Return type**
int

**rollback**(*to*)

**Return type**
None

**Parameters**
**to** (*int*)

**commit**(*to*)

Discard undo information past the given checkpoint. If the checkpoint is 0, stop recording entirely.

**Return type**
None

**Parameters**
**to** (*int*)

**graph_add_edge**(*src*, *dst*, ***data*)

**Return type**
None

**graph_strip_entry_tags**(*src*, *dst*)

Drop the abnormal_entry / normal_entry tags of an edge.

**Return type**
None

**graph_remove_edge**(*src*, *dst*)

**Return type**
None

**class** angr.analyses.decompiler.region_overlay.**RegionOverlay**

Bases: Generic[T]

A single-entry region marked over the complete graph held by an OverlayManager. The region tree is built out of RegionOverlay objects (RegionIdentifier emits them) and they are the only region type the decompiler uses.

Overlays form a tree (nested, never overlapping). An overlay's members are either complete-graph nodes it owns directly or child overlays. The region graph and the region graph-with-successors are derived on demand from the complete graph by quotienting child overlays into single nodes; *successors* are likewise derived from edges that cross the region boundary, so they can never go stale.

Read-only API (`head`, `graph`, `graph_with_successors`, `successors`, `cyclic`, `addr`) mirrors the region container consumers expect; `graph`/`graph_with_successors`/`successors` are lazy zero-copy views.

Mutation verbs:

- true structural changes (`add_node`, `remove_node`, `add_edge`, `detach_edge`, `replace_nodes`) pass through to the complete graph, so the effects are immediately visible to all enclosing regions;
- `hide_edge` removes an edge from this overlay's views only (the old "remove it from region graphs but keep the parent edge" pattern);
- `finalize(result_node)` collapses a fully-structured region into a single node of its parent;
- `dissolve()` merges an unsuccessfully-structured region back into its parent.

**__init__**(*mgr*, *head*, *cyclic*, *cyclic_ancestor=False*, *parent=None*)

**Parameters**

- **mgr** (OverlayManager[T])

- **head** (*Tx[T] | None*)
- **cyclic** (*bool*)
- **cyclic_ancestor** (*bool*)
- **parent** (*RegionOverlay | None*)

**head**

**cyclic**

**cyclic_ancestor**

**parent**

**children:** *list[RegionOverlay]*

**edge_marks:** *defaultdict[str, set[tuple[Tx[T], Tx[T]]]]*

**replacement**

**property addr**

**property manager:** *OverlayManager[T]*

**property members:** *set[Tx[T]]*

**ancestors**()

All overlays enclosing this one, including this one itself.

**Return type**
set[*RegionOverlay*]

**underlying_nodes**()

All complete-graph nodes inside this region (including nodes of nested regions).

**Return type**
set[T]

**create_subregion**(*head*, *members*, *cyclic*, *cyclic_ancestor=False*)

Carve a new child overlay out of this overlay. `members` must be a subset of this overlay's members (complete-graph nodes owned by this overlay and/or existing child overlays); `head` must be one of them.

**Return type**
*RegionOverlay*[T]

**Parameters**

- **head** (*Tx[T]*)
- **members** (*Iterable*)
- **cyclic** (*bool*)
- **cyclic_ancestor** (*bool*)

**representative**(*node*)

The node standing for a complete-graph node in this overlay's with-successors view.

**Return type**
| None

**Parameters**
**node** (*T*)

**successor_nodes**()

The derived successor set of this region: representatives of all complete-graph nodes targeted by edges leaving the region.

**Return type**
set[]

**view_graph**(*full=False*, *include_marked=False*, *blacklisted_edges=frozenset({})*)

A zero-copy, networkx-compatible view of this region (see RegionOverlayGraph).

**Return type**
*RegionOverlayGraph*[T]

**Parameters**

- **full** (*bool*)
- **include_marked** (*bool*)
- **blacklisted_edges** (*frozenset*)

**view**()

The region graph (members only): a zero-copy networkx-compatible view; treat it as read-only.

**Return type**
*RegionOverlayGraph*[T]

**view_with_successors**()

The region graph including successor nodes: a zero-copy view; treat it as read-only.

**Return type**
*RegionOverlayGraph*[T]

**property raw_graph: *RegionOverlayGraph*[T]**

The member view including marked edges (the old graph with cyclic_refinement_outgoing attrs present).

**property raw_graph_with_successors: *RegionOverlayGraph*[T]**

The with-successors view including marked edges.

**property graph: networkx.DiGraph[*Tx*[T]]**

**property graph_with_successors: networkx.DiGraph[*Tx*[T]]**

**property successors: set[*Tx*[T]]**

**property full_graph: None**

**complete_graph_entry_count**(*node*)

The number of edges entering a node in the complete graph, counted over every region. For a region object, the entries of its head from outside the region (its own back edges do not count).

**Return type**
int

**Parameters**
**node** (*Tx[T]*)

**external_entry_count**(*node*)

The number of edges entering a node (a successor of this region) from nodes that are not under this region: the entries it keeps once every edge from this region to it has been virtualized.

**Return type**
int

**Parameters**
**node** (Tx[T])

**add_node**(*node*)

Insert a new node into the complete graph as a direct member of this region.

**Return type**
None

**remove_node**(*node*, *absorbed_into=None*, *absorb_out_edges=True*)

Remove a node. If node is a member (or a member overlay's node), it is removed from the complete graph for real. If it is a successor of this region, the removal is interpreted as hiding all edges from this region to it (the successor belongs to an enclosing region and must survive).

When the node's content has been absorbed into another node during structuring, pass that node as absorbed_into: in-edges from outside this region (e.g. abnormal loop entries) are then rewired to it instead of being dropped, so enclosing regions keep their entry edges. With absorb_out_edges (the default), out-edges crossing the region boundary (e.g. loop exits) are rewired to it as well, so the complete graph never loses the region's exit flow; pass False only when the caller re-establishes every successor edge explicitly.

**Return type**
None

**Parameters**

- **node** (Tx[T])
- **absorbed_into** (Tx[T] | None)
- **absorb_out_edges** (bool)

**hide_edge_to_successor**(*succ*)

**Return type**
None

**underlying_edge_pairs**(*src*, *dst*)

**Return type**
list[tuple[, ]]

**Parameters**

- **src** (Tx[T])
- **dst** (Tx[T])

**add_edge**(*src*, *dst*, ***data*)

Add a real edge to the complete graph. Overlay endpoints are resolved to underlying nodes: the destination resolves to its entry (head chain); overlay sources are not supported. Endpoints that are not in the complete graph yet become members of this region (mirroring networkx's implicit node creation).

**Return type**
None

**Parameters**

- **src** (Tx[T])
- **dst** (Tx[T])

**detach_raw_edge**(*u*, *v*)

Remove exactly one complete-graph edge. Unlike detach_edge, other edges between the view nodes representing u and v are kept (e.g. a block that jumps both to a loop's entry and into its body).

**Return type**
None

**Parameters**

- **u** (*T*)
- **v** (*T*)

**detach_edge**(*src*, *dst*)

Remove an edge from the complete graph for real (e.g., when the edge has been virtualized into a goto). Overlay endpoints remove all underlying edges between the two node sets.

**Return type**
None

**Parameters**

- **src** (Tx[T])
- **dst** (Tx[T])

**mark_edge**(*src*, *dst*, ***attrs*)

Mark a view-level edge (e.g. cyclic_refinement_outgoing) so RegionOverlayGraph hides it by default. Marks live in overlay state, never reach the complete graph, and are remapped/cleared with the region.

**Return type**
None

**Parameters**

- **src** (Tx[T])
- **dst** (Tx[T])

**absorb_successor_into**(*succ*, *new_node*)

Absorb a successor node into a structured member node in this region's with-successors view only (the successor still belongs to an enclosing region): the successor's view out-edges are re-attached to the member node as view-only extra edges, then the successor disappears from this region's views.

**Return type**
None

**Parameters**

- **succ** (Tx[T])
- **new_node** (Tx[T])

**drop_edge_marks_from**(*node*, *key*)

Clear marks on all out-edges of a node (the new_node after a replace), undoably.

**Return type**
None

**Parameters**

- **node** (*Tx[T]*)
- **key** (*str*)

**remove_edge_with_successors_only**(*src*, *dst*)

Hide an edge from the with-successors view only, leaving the member view and the complete graph alone (a rare asymmetric bookkeeping pattern in Phoenix's switch-case structuring).

**Return type**
None

**Parameters**

- **src** (*Tx[T]*)
- **dst** (*Tx[T]*)

**hide_edge**(*src*, *dst*)

Remove an edge from this overlay's views only. Enclosing regions still see the underlying edge(s).

**Return type**
None

**Parameters**

- **src** (*Tx[T]*)
- **dst** (*Tx[T]*)

**replace_nodes**(*old_node_0*, *new_node*, *old_node_1=None*, *self_loop=True*)

Replace one or two member nodes with a new node, preserving and rewiring all underlying edges (including edges from/to nodes outside this region, which is how results become visible to enclosing regions).

Mirrors StructurerBase.replace_nodes, with one deliberate difference: in-edges of `old_node_1` from outside this region are rewired to `new_node` instead of being dropped (they are entry edges owned by enclosing regions, e.g. abnormal loop entries).

**Return type**
None

**Parameters**

- **old_node_0** (*Tx[T]*)
- **new_node** (*Tx[T]*)
- **old_node_1** (*Tx[T] | None*)
- **self_loop** (*bool*)

**snapshot_successors**()

Capture this region's structural successors and how many member edges reach each, taken before the region is structured. finalize() uses it to re-establish the region-to-successor edges that structuring removes when it refines the corresponding control-flow edges into breaks, and to tell successors whose every member edge was virtualized into a goto (see detach_edge()).

**Return type**
dict[, int]

**finalize**(*result_node=None*, *succ_snapshot=None*)

Collapse this fully-structured region into its parent: the region must consist of a single member node (the structuring result), which takes the region's place among the parent's members. Returns that node.

`succ_snapshot` (from snapshot_successors() before structuring) is used to re-establish the edges from result_node to the region's successors: structuring may have removed the live control-flow edges (refining them into breaks), but the structured region still flows to those successors and enclosing regions must see that.

A successor whose every member edge was virtualized into a goto (detach_edge()) is a pure goto target and must NOT be reconnected. Consider a loop with two exits, where `err` is shared with other loops of the function:

```
    while (1) {
        if (s->bsLive >= 8) break;              // exit A: the loop successor
        if (s->strm->avail_in == 0) goto err;  // exit B: virtualized into a␣
↪goto by cyclic refinement
        refill();
    }
    uc = take_bits();                           // A
    ...
err:
    retVal = BZ_DATA_ERROR;
    goto save_state_and_return;
```

The loop region has successors A and err. Cyclic refinement keeps A as the loop successor (a break) and turns the exit to err into a goto statement, removing that edge from the complete graph. Reconnecting err here would give the loop node two successors in the parent region, one real and one fictitious: the ITE schema finds no conditions on them, the sequence schema needs a single successor, and last-resort refinement keeps both edges because each target would be orphaned, so the parent region can never be structured. With only A reconnected, the loop node is sequenced with A as usual and err stays reachable through its gotos. Cyclic refinement never virtualizes an exit that is its target's only entry in the complete graph: the region bails and dissolves into its parent, where the target is a member and the acyclic schemas structure it with the loop.

**Parameters**

- **result_node** (*Tx[T] | None*)
- **succ_snapshot** (*set[Tx[T]] | None*)

**collapse_to**(*result_node*)

Collapse this region into its parent by replacing all of its member nodes with a single external result node (the structuring result). Used by structurers that compute their result without destructively reducing the complete graph (e.g. DreamStructurer): the region's members are still present, so their crossing in/out edges are rewired onto `result_node` and the members are removed. Returns result_node.

This is the non-self-collapsing counterpart of finalize(); the legacy GraphRegion path called replace_region() for the same purpose.

**Parameters**

**result_node** (*RegionOverlay[T]*)

**dissolve**()

Merge this region back into its parent (the failure path of structuring): members are reparented, and edges hidden in this region stay hidden in the parent (matching how partially-structured region graphs were merged back before).

**Return type**
None

class angr.analyses.decompiler.region_overlay.**RegionOverlayGraph**

Bases: DiGraph, Generic[T]

A read-only, networkx-compatible view of a RegionOverlay that stores no copy of the region's subgraph: all queries traverse the original complete graph through the overlay's membership. Compatible with every networkx algorithm and DiGraph read method because the graph's storage mappings are replaced with lazy atlases.

- `full` selects the with-successors view (the old graph_with_successors) over the member view.
- Edges marked through RegionOverlay.mark_edge (e.g. cyclic_refinement_outgoing) are filtered out by default; pass `all_edges=True` to the query methods, or use with_all_edges(), to include them.
- to_acyclic() derives a view with additional edges blacklisted (e.g. the region head's in-edges), replacing the acyclic graph copies that structuring used to make.

**property full_view:** *RegionOverlayGraph*[T]

The with-successors sibling of this view (zero-copy).

**property member_view:** *RegionOverlayGraph*[T]

The members-only sibling of this view (zero-copy).

**with_all_edges**()

A sibling view that includes edges marked through RegionOverlay.mark_edge.

**Return type**
*RegionOverlayGraph*[T]

**filtered**()

A sibling view that hides edges marked through RegionOverlay.mark_edge (the default).

**Return type**
*RegionOverlayGraph*[T]

**to_acyclic_by_order**(*node_order*)

An acyclic view of this graph, obtained by blacklisting back edges (edges whose source is ordered at or after their destination in `node_order`). Replaces utils.graph.to_acyclic_graph without a copy.

**Return type**
*RegionOverlayGraph*[T]

**Parameters**
**node_order** (*Mapping[Tx[T], int]*)

**to_acyclic**(*blacklisted_edges*)

A new view with the given (view-level) edges additionally blacklisted; used to traverse the region as an acyclic graph without copying it.

**Return type**
*RegionOverlayGraph*[T]

**Parameters**
**blacklisted_edges** (*Sequence[tuple[Tx[T], Tx[T]]]*)

**reverse_view**()

The reversed view of this graph (zero-copy).

**Return type**
*RegionOverlayGraph*[T]

**materialize**()

An independent networkx.DiGraph copy of this view.

**Return type**
networkx.DiGraph[Tx[T]]

**edge_marked**(*u*, *v*, *mark_name=None*)

**Return type**
bool

**Parameters**

- **u** (*Tx[T]*)
- **v** (*Tx[T]*)
- **mark_name** (*str | None*)

## angr.analyses.decompiler.region_simplifiers

**class** angr.analyses.decompiler.region_simplifiers.**RegionSimplifier**

Bases: *Analysis*

Simplifies a given region.

**__init__**(*func*, *region*, *ail_manager*, *arg_vvars=None*, *simplify_switches=True*, *simplify_ifelse=True*, *variable_manager=None*, *loopctr_naming=True*)

**Parameters**

- **ail_manager** (*Manager*)
- **arg_vvars** (*set[int] | None*)
- **simplify_switches** (*bool*)
- **simplify_ifelse** (*bool*)
- **variable_manager** (*VariableManagerInternal | None*)
- **loopctr_naming** (*bool*)

### angr.analyses.decompiler.region_simplifiers.cascading_cond_transformer

**class** angr.analyses.decompiler.region_simplifiers.cascading_cond_transformer.**CascadingConditionTransformer**

Bases: *SequenceWalker*

Identifies and transforms *if { … } else { if { … } else { … } }* to *if { … } else if { … } else if { … }*.

**__init__**(*node*, *manager*)

**Parameters**
**manager** (*Manager*)

### angr.analyses.decompiler.region_simplifiers.cascading_ifs

**class** angr.analyses.decompiler.region_simplifiers.cascading_ifs.**CascadingIfsRemover**

Bases: *SequenceWalker*

Coalesce cascading If constructs. Transforming the following construct:

```
if (cond_a) {
    if (cond_b) {
        true_body
    } else { }
} else { }
```

into:

```
if (cond_a and cond_b) {
    true_body
} else { }
```

**__init__**(*node*, *manager*)

### angr.analyses.decompiler.region_simplifiers.expr_folding

**class** angr.analyses.decompiler.region_simplifiers.expr_folding.**LocationBase**

Bases: object

**class** angr.analyses.decompiler.region_simplifiers.expr_folding.**StatementLocation**

Bases: *LocationBase*

Describes the location of a statement.

**__init__**(*block_addr*, *block_idx*, *stmt_idx*, *phi_stmt=False*)

**Parameters**
**phi_stmt** (*bool*)

**block_addr**

**block_idx**

**stmt_idx**

**phi_stmt**

copy()

class angr.analyses.decompiler.region_simplifiers.expr_folding.**ExpressionLocation**

Bases: *LocationBase*

Describes the location of an expression.

__init__(*block_addr*, *block_idx*, *stmt_idx*, *expr_idx*, *phi_stmt=False*)

**Parameters**
**phi_stmt** (*bool*)

block_addr

block_idx

stmt_idx

expr_idx

phi_stmt

statement_location()

**Return type**
*StatementLocation*

class angr.analyses.decompiler.region_simplifiers.expr_folding.**ConditionLocation**

Bases: *LocationBase*

Describes the location of a condition.

__init__(*cond_node_addr*, *case_idx=None*)

**Parameters**
**case_idx** (*int | None*)

node_addr

case_idx

class angr.analyses.decompiler.region_simplifiers.expr_folding.**ConditionalBreakLocation**

Bases: *LocationBase*

Describes the location of a conditional break.

__init__(*node_addr*)

node_addr

class angr.analyses.decompiler.region_simplifiers.expr_folding.**LoopNodeFinder**

Bases: *SequenceWalker*

Returns all loops in a given region.

__init__(*node*)

**Parameters**
**node** (SequenceNode)

loop_nodes: list[*LoopNode*]

class angr.analyses.decompiler.region_simplifiers.expr_folding.MultiStatementExpressionAssignmentFinder

Bases: *AILBlockRewriter*

Process statements in MultiStatementExpression objects and find assignments.

__init__(*stmt_handler*)

class angr.analyses.decompiler.region_simplifiers.expr_folding.ExpressionUseFinder

Bases: *AILBlockRewriter*

Find where each variable is used.

Additionally, determine if the expression being walked has load expressions inside. Such expressions can only be safely folded if there are no Store statements between the expression defining location and its use sites. For example, we can only safely fold variable assignments that use Load() when there are no Store()s between the assignment and its use site. Otherwise, the loaded expression may get updated later by a Store() statement.

Here is a real AIL block:

```
v16 = ((int)v23->field_5) + 1 & 255;
v23->field_5 = ((char)(((int)v23->field_5) + 1 & 255));
v13 = printf("Recieved packet %d for connection with %d\n", v16, a0 & 255);
```

In this case, folding v16 into the last printf() expression would be incorrect, since v23->field_5 is updated by the second statement.

__init__()

uses: defaultdict[int, set[tuple[*Expression*, *ExpressionLocation* | None]]]

has_load

class angr.analyses.decompiler.region_simplifiers.expr_folding.ExpressionCounter

Bases: *SequenceWalker*

Find all expressions that are assigned once and only used once.

__init__(*node*)

assignments: defaultdict[Any, set[tuple]]

outerscope_uses: dict[int, set[tuple[*Expression*, *LocationBase* | None]]]

all_uses: dict[int, set[tuple[*Expression*, *LocationBase* | None]]]

class angr.analyses.decompiler.region_simplifiers.expr_folding.ExpressionSpotter

Bases: *VVarUsesCollector*

ExpressionSpotter collects uses of vvars and existence of Call expressions.

__init__()

has_calls: bool

has_loads: bool

class angr.analyses.decompiler.region_simplifiers.expr_folding.**InterferenceChecker**

Bases: *SequenceWalker*

Detect for every pair of definition (assignment) - use if there is anything that may interfere with the definition.

Interferences may be caused by:

- another call
- function return
- store statements
- load expressions
- Condition and CascadingCondition nodes

**__init__**(*assignments*, *uses*, *node*, *variable_map*)

**Parameters**

- **assignments** (*dict[int, Any]*)
- **uses** (*dict[int, Any]*)

**interfered_assignments:** `set[int]`

class angr.analyses.decompiler.region_simplifiers.expr_folding.**ExpressionReplacer**

Bases: *AILBlockRewriter*

**__init__**(*assignments*, *uses*, *variable_map*)

**Parameters**

- **assignments** (*dict[int, Any]*)
- **uses** (*dict[int, Any]*)

class angr.analyses.decompiler.region_simplifiers.expr_folding.**ExpressionFolder**

Bases: *SequenceWalker*

**__init__**(*assignments*, *uses*, *node*, *variable_map*)

**Parameters**

- **assignments** (*dict[int, Any]*)
- **uses** (*dict[int, Any]*)

class angr.analyses.decompiler.region_simplifiers.expr_folding.**StoreStatementFinder**

Bases: *SequenceWalker*

Determine if there are any Store statements between two given statements.

This class overrides _handle_Sequence() and _handle_MultiNode() to ensure they traverse nodes from top to bottom.

**__init__**(*node*, *intervals*)

**Parameters**
**intervals** (*Iterable[tuple[StatementLocation, LocationBase]]*)

**interval_to_hasstore:** `dict[tuple[StatementLocation, StatementLocation], bool]`

**has_store**(*start*, *end*)

**Return type**
bool

**Parameters**

- **start** (StatementLocation)
- **end** (StatementLocation)

### angr.analyses.decompiler.region_simplifiers.goto

**class** angr.analyses.decompiler.region_simplifiers.goto.**GotoSimplifier**

Bases: *SequenceWalker*

Remove unnecessary Jump statements. This simplifier also has the side effect of detecting Gotos that can't be reduced in the structuring and eventual decompilation output. Because of this, when this analysis is run, gotos in decompilation will be detected and stored in the kb.gotos. See the _handle_irreducible_goto function below.

TODO: Move the recording of Gotos outside this function

**__init__**(*node*, *function=None*, *kb=None*)

### angr.analyses.decompiler.region_simplifiers.if_

**class** angr.analyses.decompiler.region_simplifiers.if_.**IfSimplifier**

Bases: *SequenceWalker*

Remove unnecessary jump or conditional jump statements if they jump to the successor right afterwards.

**__init__**(*node*)

### angr.analyses.decompiler.region_simplifiers.ifelse

**class** angr.analyses.decompiler.region_simplifiers.ifelse.**IfElseFlattener**

Bases: *SequenceWalker*

Remove unnecessary else branches and make the else node a direct successor of the previous If node if the If node always returns.

**__init__**(*node*, *functions*)

### angr.analyses.decompiler.region_simplifiers.loop

**class** angr.analyses.decompiler.region_simplifiers.loop.**LoopSimplifier**

Bases: *SequenceWalker*

Simplifies loops.

**__init__**(*node*, *functions*)

### angr.analyses.decompiler.region_simplifiers.node_address_finder

**class** angr.analyses.decompiler.region_simplifiers.node_address_finder.**NodeAddressFinder**

Bases: *SequenceWalker*

Walk the entire node and collect all addresses of nodes.

**__init__**(*node*)

### angr.analyses.decompiler.region_simplifiers.region_simplifier

class angr.analyses.decompiler.region_simplifiers.region_simplifier.**RegionSimplifier**

Bases: *Analysis*

Simplifies a given region.

**__init__**(*func*, *region*, *ail_manager*, *arg_vvars=None*, *simplify_switches=True*, *simplify_ifelse=True*, *variable_manager=None*, *loopctr_naming=True*)

**Parameters**

- **ail_manager** (*Manager*)
- **arg_vvars** (*set[int] | None*)
- **simplify_switches** (*bool*)
- **simplify_ifelse** (*bool*)
- **variable_manager** (*VariableManagerInternal | None*)
- **loopctr_naming** (*bool*)

### angr.analyses.decompiler.region_simplifiers.switch_cluster_simplifier

class angr.analyses.decompiler.region_simplifiers.switch_cluster_simplifier.**CmpOp**

Bases: Enum

All supported comparison operators.

**LT = 0**

**GT = 1**

**EQ = 2**

**NE = 3**

class angr.analyses.decompiler.region_simplifiers.switch_cluster_simplifier.**ConditionalRegion**

Bases: object

Describes a conditional region.

**__init__**(*variable*, *op*, *value*, *node*, *parent=None*)

**Parameters**

- **op** (*CmpOp*)
- **value** (*int*)
- **node** (*ConditionNode | Block*)

**variable**

**op**

**value**

**node**

**parent**

**class** angr.analyses.decompiler.region_simplifiers.switch_cluster_simplifier.**SwitchCaseRegion**

Bases: object

Describes an already-recovered switch region.

**__init__**(*variable*, *node*, *parent=None*)

**Parameters**
**node** (SwitchCaseNode)

**variable**

**node**

**parent**

**class** angr.analyses.decompiler.region_simplifiers.switch_cluster_simplifier.**SwitchClusterFinder**

Bases: *SequenceWalker*

Find comparisons and switches in order to identify switch clusters.

**__init__**(*node*, *variable_map*)

**var2condnodes:** defaultdict[Any, list[*ConditionalRegion*]]

**var2switches:** defaultdict[Any, list[*SwitchCaseRegion*]]

**class** angr.analyses.decompiler.region_simplifiers.switch_cluster_simplifier.**SwitchClusterReplacer**

Bases: *SequenceWalker*

Replace an identified switch cluster with a newly created SwitchCase node.

**__init__**(*region*, *to_replace*, *replace_with*)

angr.analyses.decompiler.region_simplifiers.switch_cluster_simplifier.**is_simple_jump_node**(*node*, *case_addrs*, *targets=None*)

**Return type**
bool

**Parameters**
**targets** (*set[int] | None*)

angr.analyses.decompiler.region_simplifiers.switch_cluster_simplifier.**filter_cond_regions**(*cond_regions*, *case_addrs*)

Remove all conditional regions that cannot be merged into switch(es).

**Return type**
list[*ConditionalRegion*]

**Parameters**

- **cond_regions** (*list[ConditionalRegion]*)
- **case_addrs** (*set[int]*)

angr.analyses.decompiler.region_simplifiers.switch_cluster_simplifier.**update_switch_case_list**(*cases*, *old_case_id*, *new_case_id*)

Update cases in-place. Make new_case_id directly jump to old_case_id.

**Return type**
None

**Parameters**

- **cases** (*list[tuple[int | tuple[int, ...], SequenceNode]]*)
- **old_case_id** (*int | tuple[int, ...]*)
- **new_case_id** (*int*)

angr.analyses.decompiler.region_simplifiers.switch_cluster_simplifier.**simplify_switch_clusters**(*region*, *var2condnodes*, *var2switches*)

Identify switch clusters and simplify each of them.

**Parameters**

- **region** – The region to simplify.
- **var2condnodes** (dict[Any, list[*ConditionalRegion*]]) – A dict that stores the mapping from (potential) switch variables to conditional regions.
- **var2switches** (dict[Any, list[*SwitchCaseRegion*]]) – A dict that stores the mapping from switch variables to switch-case regions.

**Returns**
None

angr.analyses.decompiler.region_simplifiers.switch_cluster_simplifier.**simplify_lowered_switches**(*region*, *var2condnodes*, *functions*, *ail_manager*)

Identify a lowered switch and simplify it into a switch-case if possible.

**Parameters**

- **region** (*SequenceNode*) – The region to simplify.
- **var2condnodes** (dict[Any, list[*ConditionalRegion*]]) – A dict that stores the mapping from (potential) switch variables to conditional regions.
- **ail_manager** (*Manager*)

**Returns**
None

angr.analyses.decompiler.region_simplifiers.switch_cluster_simplifier.**simplify_lowered_switches_core**(*reg*, *var*, *con*, *fun*, *tio*, *ail_*)

**Return type**
bool

**Parameters**

- **region** (SequenceNode)
- **ail_manager** (*Manager*)

**class** angr.analyses.decompiler.region_simplifiers.switch_cluster_simplifier.**FindFirstNodeInSet**

Bases: *SequenceWalker*

Find the first node out of a set of node appearing in a SequenceNode (and its tree).

**__init__**(*node_set*)

**Parameters**

**node_set** (*set[BaseNode]*)

### angr.analyses.decompiler.region_simplifiers.switch_expr_simplifier

**class** angr.analyses.decompiler.region_simplifiers.switch_expr_simplifier.**SwitchExpressionSimplifier**

Bases: *SequenceWalker*

Identifies switch expressions that adds or minuses a constant, removes the constant from the switch expression, and adjust all case expressions accordingly.

**__init__**(*node*, *manager*)

**Parameters**

**manager** (*Manager*)

### angr.analyses.decompiler.region_walker

**class** angr.analyses.decompiler.region_walker.**RegionWalker**

Bases: object

A simple traverser class that walks RegionOverlay instances.

**__init__**()

**walk**(*region*)

**Parameters**

**region** (RegionOverlay)

**walk_node**(*region*, *node*)

### angr.analyses.decompiler.return_maker

**class** angr.analyses.decompiler.return_maker.**ReturnMaker**

Bases: *AILGraphWalker*

Traverse the AILBlock graph of a function and update .ret_exprs of all return statements.

**__init__**(*ail_manager*, *arch*, *function*, *ail_graph*, *flavor=Flavors.DEFAULT_FLAVOR*, *cc=None*)

**Parameters**

- **flavor** (*str*)
- **cc** (SimCC | *None*)

### angr.analyses.decompiler.semantic_naming

Semantic variable naming patterns for the decompiler.

This package provides various patterns for automatically naming variables based on their semantic usage (loop counters, array indices, etc.).

The naming passes are split into two categories: - Clinic-based passes: Run on the AIL graph before structuring (ClinicNamingBase) - Region-based passes: Run after structuring on the structured region (RegionNamingBase)

Loop counter naming is a Region-based pass that runs in RegionSimplifier to leverage the structured LoopNode information.

**class** angr.analyses.decompiler.semantic_naming.**ArrayIndexNaming**

Bases: *ClinicNamingBase*

Detects variables used as array indices and renames them.

Array index patterns detected: - base + idx * scale (common array indexing) - base + idx (byte array or pointer arithmetic) - ptr[idx] style access

**PRIORITY: int = 50**

**__init__**(**args*, ***kwargs*)

**analyze**()

Analyze the graph for array index patterns.

**Return type**
dict[*SimVariable*, str]

**Returns**
Dictionary mapping SimVariable to new name

**class** angr.analyses.decompiler.semantic_naming.**BooleanNaming**

Bases: *ClinicNamingBase*

Detects variables used as boolean flags and renames them.

Boolean flag patterns detected: - Variables assigned only 0 or 1 - Variables used directly in conditions (if (var) or if (!var)) - Variables compared to 1 - Variables that are results of comparison operations

**PRIORITY: int = 80**

**__init__**(**args*, ***kwargs*)

**analyze**()

Analyze the graph for boolean flag patterns.

**Return type**
dict[*SimVariable*, str]

**Returns**
Dictionary mapping SimVariable to new name

**class** angr.analyses.decompiler.semantic_naming.**CallResultNaming**

Bases: *ClinicNamingBase*

Detects variables that store function call results and names them based on the called function.

**PRIORITY: int = 40**

**__init__**(**args*, ***kwargs*)

**analyze**()

Analyze the graph for function call result patterns.

**Return type**
dict[*SimVariable*, str]

**Returns**
Dictionary mapping SimVariable to new name

**class** angr.analyses.decompiler.semantic_naming.**ClinicNamingBase**

Bases: *SemanticNamingBase*

Base class for semantic naming passes that run in Clinic on AIL graphs.

These passes operate on the raw AIL graph before structuring, allowing them to analyze control flow patterns directly.

**__init__**(*ail_graph*, *variable_manager*, *functions*, *entry_node*, *variable_map*)

**Parameters**

- **ail_graph** (*networkx.DiGraph*)
- **variable_manager** (VariableManagerInternal)
- **functions** (FunctionManager)
- **entry_node** (Block)
- **variable_map** (VariableMap)

**class** angr.analyses.decompiler.semantic_naming.**PointerNaming**

Bases: *ClinicNamingBase*

Detects variables used as pointers and renames them.

Pointer patterns detected: - Variables used as addresses in Load/Store operations - Variables involved in pointer arithmetic - Variables passed to functions expecting pointers - Variables receiving pointer-returning function results - Variables used in linked-list patterns (next/prev access)

**PRIORITY: int = 45**

**__init__**(**args*, ***kwargs*)

**analyze**()

Analyze the graph for pointer variable patterns.

**Return type**
dict[*SimVariable*, str]

**Returns**
Dictionary mapping SimVariable to new name

**class** angr.analyses.decompiler.semantic_naming.**RegionLoopCounterNaming**

Bases: *RegionNamingBase*

Detects loop counter variables from structured LoopNodes and renames them to standard names like i, j, k based on nesting depth.

This pass operates after structuring and uses the iterator information already extracted by LoopSimplifier (stored in LoopNode.iterator).

**PRIORITY: int = 10**

**__init__**(*region*, *variable_manager*, *functions*, *variable_map*)

**Parameters**

- **region** (BaseNode)
- **variable_manager** (VariableManagerInternal)
- **functions** (FunctionManager)

**analyze**()

Analyze the structured region for loop counters and return a mapping of variables to their new names.

**Return type**
dict[*SimVariable*, str]

**Returns**
Dictionary mapping SimVariable to new name (e.g., "i", "j", "k")

**class** angr.analyses.decompiler.semantic_naming.**RegionNamingBase**

Bases: *SemanticNamingBase*

Base class for semantic naming passes that run in RegionSimplifier on structured regions.

These passes operate after structuring, allowing them to leverage structured information like LoopNode, ConditionNode, etc. They can reuse loop analysis results from structuring instead of re-analyzing the graph.

**__init__**(*region*, *variable_manager*, *functions*, *variable_map*)

**Parameters**

- **region** (BaseNode)
- **variable_manager** (VariableManagerInternal)
- **functions** (FunctionManager)

**class** angr.analyses.decompiler.semantic_naming.**SemanticNamingBase**

Bases: ABC

Abstract base class for semantic variable naming patterns.

Subclasses implement specific naming patterns (loop counters, array indices, etc.) This is the common base for both Clinic-based and RegionSimplifier-based passes.

**PRIORITY: int = 100**

**__init__**(*variable_manager*, *functions*, *variable_map*)

**Parameters**

- **variable_manager** (VariableManagerInternal)
- **functions** (FunctionManager)
- **variable_map** (VariableMap)

**original_names: dict[*SimVariable*, str | None]**

**abstractmethod analyze**()

Analyze and return a mapping of variables to their suggested names.

**Return type**
dict[*SimVariable*, str]

**Returns**
Dictionary mapping SimVariable to suggested name

**apply_names**(*exclude_vars=None*)

Apply the computed names to the variables.

**Parameters**
**exclude_vars** (set[*SimVariable*] | None) – Variables to skip (already named by higher priority patterns)

**Return type**
set[*SimVariable*]

**Returns**
Set of variables that were renamed

**class** angr.analyses.decompiler.semantic_naming.**SemanticNamingOrchestrator**

Bases: object

Orchestrates multiple semantic naming patterns.

Runs each pattern in priority order (lower PRIORITY value = runs first). Variables named by higher-priority patterns are not renamed by lower-priority ones.

**__init__**(*ail_graph*, *variable_manager*, *functions*, *entry_node*, *variable_map=None*, *patterns=None*)

**Parameters**
- **ail_graph** (*networkx.DiGraph*)
- **variable_manager** (VariableManagerInternal)
- **functions** (FunctionManager)
- **entry_node** (*ailment.Block*)
- **patterns** (*list[type[ClinicNamingBase]] | None*)

**analyze**()

Run all semantic naming patterns in priority order.

**Return type**
dict[*SimVariable*, str]

**Returns**
Combined mapping of all renamed variables to their new names

**MAX_SHARED_NAME = 3**

**resolve_name_collisions**()

Suffix duplicate names (len, len1, ...) so each variable is unique.

Two distinct variables can get the same name (two strlen -> "len", or CallResultNaming and PointerNaming both -> "ptr").

Once a base name has been used *MAX_SHARED_NAME* times, any further variables that would reuse it are reverted to default (auto-generated) naming: a long run of near-identical names (ptr1 ... ptr19) does not help a reader more than the default names would.

**Return type**
None

**class** angr.analyses.decompiler.semantic_naming.**SizeNaming**

Bases: *ClinicNamingBase*

Detects variables used as sizes, lengths, or counts based on: 1. Being passed as size parameters to known functions 2. Being used in loop bounds (compared with loop counters) 3. Having names that suggest size semantics

**PRIORITY: int = 70**

**__init__**(**args*, ***kwargs*)

**analyze**()

Analyze the graph for size/length variable patterns.

**Return type**
dict[*SimVariable*, str]

**Returns**
Dictionary mapping SimVariable to new name

## Submodules

### angr.analyses.decompiler.semantic_naming.array_index_naming

Semantic variable naming for array indices.

This module detects variables used as array indices and names them appropriately.

**class** angr.analyses.decompiler.semantic_naming.array_index_naming.**ArrayIndexNaming**

Bases: *ClinicNamingBase*

Detects variables used as array indices and renames them.

Array index patterns detected: - base + idx * scale (common array indexing) - base + idx (byte array or pointer arithmetic) - ptr[idx] style access

**PRIORITY: int = 50**

**__init__**(**args*, ***kwargs*)

**analyze**()

Analyze the graph for array index patterns.

**Return type**
dict[*SimVariable*, str]

**Returns**
Dictionary mapping SimVariable to new name

### angr.analyses.decompiler.semantic_naming.boolean_naming

Semantic variable naming for boolean flag variables.

This module detects variables used as boolean flags and names them appropriately (e.g., found, done, flag, ok).

**class** angr.analyses.decompiler.semantic_naming.boolean_naming.**BooleanNaming**

Bases: *ClinicNamingBase*

Detects variables used as boolean flags and renames them.

Boolean flag patterns detected: - Variables assigned only 0 or 1 - Variables used directly in conditions (if (var) or if (!var)) - Variables compared to 1 - Variables that are results of comparison operations

**PRIORITY: int = 80**

**__init__**(**args*, ***kwargs*)

**analyze**()

Analyze the graph for boolean flag patterns.

**Return type**
dict[*SimVariable*, str]

**Returns**
Dictionary mapping SimVariable to new name

### angr.analyses.decompiler.semantic_naming.call_result_naming

Semantic variable naming for function call results.

This module detects variables that store function call results and names them based on the called function (e.g., malloc result -> ptr, strlen result -> len).

**class** angr.analyses.decompiler.semantic_naming.call_result_naming.**CallResultNaming**

Bases: *ClinicNamingBase*

Detects variables that store function call results and names them based on the called function.

**PRIORITY: int = 40**

**__init__**(**args*, ***kwargs*)

**analyze**()

Analyze the graph for function call result patterns.

**Return type**
dict[*SimVariable*, str]

**Returns**
Dictionary mapping SimVariable to new name

### angr.analyses.decompiler.semantic_naming.naming_base

Base class for semantic variable naming patterns.

This module provides two base classes for semantic naming: - ClinicNamingBase: For passes running in Clinic on AIL graphs - RegionNamingBase: For passes running in RegionSimplifier on structured regions

class angr.analyses.decompiler.semantic_naming.naming_base.**SemanticNamingBase**

Bases: ABC

Abstract base class for semantic variable naming patterns.

Subclasses implement specific naming patterns (loop counters, array indices, etc.) This is the common base for both Clinic-based and RegionSimplifier-based passes.

**PRIORITY: int = 100**

**__init__**(*variable_manager*, *functions*, *variable_map*)

**Parameters**

- **variable_manager** (VariableManagerInternal)
- **functions** (FunctionManager)
- **variable_map** (VariableMap)

**original_names: dict[*SimVariable*, str | None]**

**abstractmethod analyze**()

Analyze and return a mapping of variables to their suggested names.

**Return type**
dict[*SimVariable*, str]

**Returns**
Dictionary mapping SimVariable to suggested name

**apply_names**(*exclude_vars=None*)

Apply the computed names to the variables.

**Parameters**
**exclude_vars** (set[*SimVariable*] | None) – Variables to skip (already named by higher priority patterns)

**Return type**
set[*SimVariable*]

**Returns**
Set of variables that were renamed

class angr.analyses.decompiler.semantic_naming.naming_base.**ClinicNamingBase**

Bases: *SemanticNamingBase*

Base class for semantic naming passes that run in Clinic on AIL graphs.

These passes operate on the raw AIL graph before structuring, allowing them to analyze control flow patterns directly.

**__init__**(*ail_graph*, *variable_manager*, *functions*, *entry_node*, *variable_map*)

**Parameters**

- **ail_graph** (*networkx.DiGraph*)
- **variable_manager** (VariableManagerInternal)
- **functions** (FunctionManager)
- **entry_node** (Block)
- **variable_map** (VariableMap)

class angr.analyses.decompiler.semantic_naming.naming_base.**RegionNamingBase**

Bases: *SemanticNamingBase*

Base class for semantic naming passes that run in RegionSimplifier on structured regions.

These passes operate after structuring, allowing them to leverage structured information like LoopNode, ConditionNode, etc. They can reuse loop analysis results from structuring instead of re-analyzing the graph.

**__init__**(*region*, *variable_manager*, *functions*, *variable_map*)

**Parameters**

- **region** (BaseNode)
- **variable_manager** (VariableManagerInternal)
- **functions** (FunctionManager)

## angr.analyses.decompiler.semantic_naming.orchestrator

Orchestrator for semantic variable naming patterns.

This module coordinates multiple naming patterns and applies them in priority order.

Note: Loop counter naming is NOT included here as it runs in RegionSimplifier after structuring, where it can leverage the structured LoopNode information.

class angr.analyses.decompiler.semantic_naming.orchestrator.**SemanticNamingOrchestrator**

Bases: object

Orchestrates multiple semantic naming patterns.

Runs each pattern in priority order (lower PRIORITY value = runs first). Variables named by higher-priority patterns are not renamed by lower-priority ones.

**__init__**(*ail_graph*, *variable_manager*, *functions*, *entry_node*, *variable_map=None*, *patterns=None*)

**Parameters**

- **ail_graph** (*networkx.DiGraph*)
- **variable_manager** (VariableManagerInternal)
- **functions** (FunctionManager)
- **entry_node** (*ailment.Block*)
- **patterns** (*list[type[ClinicNamingBase]] | None*)

**renamed_variables**: set[*SimVariable*]

**variable_patterns**: dict[*SimVariable*, str]

**original_names**: dict[*SimVariable*, str | None]

**analyze**()

Run all semantic naming patterns in priority order.

**Return type**
dict[*SimVariable*, str]

**Returns**
Combined mapping of all renamed variables to their new names

**MAX_SHARED_NAME = 3**

**resolve_name_collisions**()

Suffix duplicate names (len, len1, ...) so each variable is unique.

Two distinct variables can get the same name (two strlen -> "len", or CallResultNaming and PointerNaming both -> "ptr").

Once a base name has been used *MAX_SHARED_NAME* times, any further variables that would reuse it are reverted to default (auto-generated) naming: a long run of near-identical names (ptr1 ... ptr19) does not help a reader more than the default names would.

**Return type**
None

### angr.analyses.decompiler.semantic_naming.pointer_naming

Semantic variable naming for pointer variables.

This module detects variables used as pointers and names them appropriately (e.g., ptr, p, cur, next, prev).

**class** angr.analyses.decompiler.semantic_naming.pointer_naming.**PointerNaming**

Bases: *ClinicNamingBase*

Detects variables used as pointers and renames them.

Pointer patterns detected: - Variables used as addresses in Load/Store operations - Variables involved in pointer arithmetic - Variables passed to functions expecting pointers - Variables receiving pointer-returning function results - Variables used in linked-list patterns (next/prev access)

**PRIORITY: int = 45**

**__init__**(**args*, ***kwargs*)

**analyze**()

Analyze the graph for pointer variable patterns.

**Return type**
dict[*SimVariable*, str]

**Returns**
Dictionary mapping SimVariable to new name

### angr.analyses.decompiler.semantic_naming.region_loop_counter_naming

Semantic variable naming for loop counters using structured regions.

This module implements detection and renaming of loop counter variables using the LoopNode structure from the region simplifier. It operates on structured regions after the structuring phase, allowing it to reuse existing loop analysis results instead of re-analyzing the graph.

**class** angr.analyses.decompiler.semantic_naming.region_loop_counter_naming.**RegionLoopCounterNaming**

Bases: *RegionNamingBase*

Detects loop counter variables from structured LoopNodes and renames them to standard names like i, j, k based on nesting depth.

This pass operates after structuring and uses the iterator information already extracted by LoopSimplifier (stored in LoopNode.iterator).

PRIORITY: int = 10

__init__(*region*, *variable_manager*, *functions*, *variable_map*)

**Parameters**

- **region** (BaseNode)
- **variable_manager** (VariableManagerInternal)
- **functions** (FunctionManager)

analyze()

Analyze the structured region for loop counters and return a mapping of variables to their new names.

**Return type**
dict[*SimVariable*, str]

**Returns**
Dictionary mapping SimVariable to new name (e.g., "i", "j", "k")

### angr.analyses.decompiler.semantic_naming.size_naming

Semantic variable naming for size/length/count variables.

This module detects variables used as sizes, lengths, or counts and names them appropriately (e.g., size, len, count, n).

class angr.analyses.decompiler.semantic_naming.size_naming.**SizeNaming**

Bases: *ClinicNamingBase*

Detects variables used as sizes, lengths, or counts based on: 1. Being passed as size parameters to known functions 2. Being used in loop bounds (compared with loop counters) 3. Having names that suggest size semantics

PRIORITY: int = 70

__init__(**args*, ***kwargs*)

analyze()

Analyze the graph for size/length variable patterns.

**Return type**
dict[*SimVariable*, str]

**Returns**
Dictionary mapping SimVariable to new name

### angr.analyses.decompiler.seq_to_blocks

class angr.analyses.decompiler.seq_to_blocks.**SequenceToBlocks**

Bases: *SequenceWalker*

A helper class to convert a sequence node into a list of blocks.

__init__()

### angr.analyses.decompiler.sequence_walker

**class** angr.analyses.decompiler.sequence_walker.**SequenceWalker**

Bases: object

Walks a SequenceNode and all its nodes, recursively.

**__init__**(*handlers=None*, *exception_on_unsupported=False*, *update_seqnode_in_place=True*, *force_forward_scan=False*)

**Parameters**
**force_forward_scan** (*bool*)

**walk**(*sequence*)

### angr.analyses.decompiler.ssailification

**class** angr.analyses.decompiler.ssailification.**Ssailification**

Bases: *Analysis*

Ssailification (SSA-AIL-ification) transforms an AIL graph to its partial-SSA form.

**__init__**(*func*, *ail_graph*, *entry=None*, *canonical_size=8*, *stack_pointer_tracker=None*, *func_addr=None*, *ail_manager=None*, *ssa_stackvars=False*, *ssa_tmps=False*, *func_args=None*, *rewrite_vvars=None*, *vvar_id_start=0*, *flavor=Flavors.DEFAULT_FLAVOR*)

**Parameters**

- **func** (*Function* | str) – The subject of the analysis: a function, or a single basic block
- **ail_graph** (networkx.DiGraph[Block]) – The AIL graph to transform.
- **canonical_size** (int) – The sizes (in bytes) that objects with an UNKNOWN_SIZE are treated as for operations where sizes are necessary.
- **entry** (*Block | None*)
- **func_addr** (*int | None*)
- **ail_manager** (*Manager | None*)
- **ssa_stackvars** (*bool*)
- **ssa_tmps** (*bool*)
- **func_args** (*set[VirtualVariable] | None*)
- **rewrite_vvars** (*set[int] | None*)
- **vvar_id_start** (*int*)
- **flavor** (*str*)

### angr.analyses.decompiler.ssailification.consts

### angr.analyses.decompiler.ssailification.rewriting

**class** angr.analyses.decompiler.ssailification.rewriting.**RewritingAnalysis**

Bases: object

RewritingAnalysis traverses the AIL graph, inserts phi nodes, and rewrites all expression uses to virtual variables when necessary.

**__init__**(*project*, *func*, *ail_graph*, *phiid_to_udef*, *block_to_phiids*, *rewrite_tmps*, *ail_manager*, *func_args*, *def_to_udef*, *extern_defs*, *incomplete_defs*, *vvar_id_start=0*, *stackvars=False*, *fail_fast=False*, *clobber_defs_by_loc=None*)

**Parameters**

- **project** (Project)
- **func** (Function)
- **ail_graph** (*networkx.DiGraph[Block]*)
- **phiid_to_udef** (*dict[int, UDef]*)
- **block_to_phiids** (*dict[Block, list[int]]*)
- **rewrite_tmps** (*bool*)
- **ail_manager** (*Manager*)
- **func_args** (*set[VirtualVariable]*)
- **def_to_udef** (*MutableMapping[Def, UDef]*)
- **extern_defs** (*set[UDef]*)
- **incomplete_defs** (*set[Def]*)
- **vvar_id_start** (*int*)
- **stackvars** (*bool*)
- **fail_fast** (*bool*)
- **clobber_defs_by_loc** (*dict[tuple[int, int, int], list[Def]] | None*)

**property max_vvar_id:** int | None

**create_phi_statements**(*node*, *phiid_to_udef*, *phi_ids*)

**Return type**
list[*Assignment*]

**Parameters**

- **node** (Block)
- **phiid_to_udef** (*dict[int, UDef]*)
- **phi_ids** (*Iterable[int]*)

**static insert_phi_statements**(*node*, *phi_stmts*)

Insert phi statements after the leading labels of the block; return the index they were inserted at.

**Return type**
int

**Parameters**

- **node** (*Block*)
- **phi_stmts** (*list[Assignment]*)

### angr.analyses.decompiler.ssailification.rewriting_engine

**class** angr.analyses.decompiler.ssailification.rewriting_engine.**SimEngineSSARewriting**

Bases: *SimEngineNostmtAIL*[*RewritingState*, *Expression* | None, *Statement* | tuple[*Statement*, ...], None]

This engine rewrites every block to insert phi variables and replaces every used variable with their versioned copies at each use location.

**__init__**(*project*, ***, *ail_manager*, *def_to_udef*, *extern_defs=None*, *incomplete_defs*, *vvar_id_start=0*, *rewrite_tmps=False*, *stackvars=False*, *fail_fast=False*, *clobber_defs_by_loc=None*)

**Parameters**

- **ail_manager** (*Manager*)
- **def_to_udef** (*MutableMapping[Def, UDef]*)
- **extern_defs** (*set[UDef] | None*)
- **incomplete_defs** (*set[Def]*)
- **vvar_id_start** (*int*)
- **rewrite_tmps** (*bool*)
- **stackvars** (*bool*)
- **fail_fast** (*bool*)
- **clobber_defs_by_loc** (*dict[tuple[int, int, int], list[Def]] | None*)

**property current_vvar_id: int**

**process**(*state*, ***, *block=None*, *whitelist=None*, ***kwargs*)

**Return type**
None

**Parameters**

- **state** (RewritingState)
- **block** (*Block | None*)
- **whitelist** (*set[int] | None*)

### angr.analyses.decompiler.ssailification.rewriting_state

class angr.analyses.decompiler.ssailification.rewriting_state.**RewritingState**

Bases: object

The abstract state for the expression rewriting engine.

**__init__**(*loc*, *arch*, *func*, *original_block*, *registers=None*, *stackvars=None*)

**Parameters**

- **loc** (AILCodeLocation)
- **original_block** (*Block*)
- **registers** (*dict[int, VirtualVariable] | None*)
- **stackvars** (IntervalMapCOW[VirtualVariable] | *None*)

**copy**()

**Return type**
*RewritingState*

**append_statement**(*stmt*)

**Parameters**
**stmt** (Statement)

### angr.analyses.decompiler.ssailification.ssailification

type angr.analyses.decompiler.ssailification.ssailification.**Kind** = Literal['stack', 'reg']

type angr.analyses.decompiler.ssailification.ssailification.**UDef** = tuple[*Kind*, int, int]

type angr.analyses.decompiler.ssailification.ssailification.**Def** = *StackBaseOffset* | *Register* | *IRegister*

class angr.analyses.decompiler.ssailification.ssailification.**Ssailification**

Bases: *Analysis*

Ssailification (SSA-AIL-ification) transforms an AIL graph to its partial-SSA form.

**__init__**(*func*, *ail_graph*, *entry=None*, *canonical_size=8*, *stack_pointer_tracker=None*, *func_addr=None*, *ail_manager=None*, *ssa_stackvars=False*, *ssa_tmps=False*, *func_args=None*, *rewrite_vvars=None*, *vvar_id_start=0*, *flavor=Flavors.DEFAULT_FLAVOR*)

**Parameters**

- **func** (*Function* | str) – The subject of the analysis: a function, or a single basic block
- **ail_graph** (networkx.DiGraph[Block]) – The AIL graph to transform.
- **canonical_size** (int) – The sizes (in bytes) that objects with an UNKNOWN_SIZE are treated as for operations where sizes are necessary.
- **entry** (Block | *None*)
- **func_addr** (*int* | *None*)
- **ail_manager** (*Manager* | *None*)
- **ssa_stackvars** (*bool*)
- **ssa_tmps** (*bool*)

- **func_args** (*set[VirtualVariable] | None*)
- **rewrite_vvars** (*set[int] | None*)
- **vvar_id_start** (*int*)
- **flavor** (*str*)

### angr.analyses.decompiler.ssailification.traversal

**class** angr.analyses.decompiler.ssailification.traversal.**TraversalAnalysis**

Bases: object

TraversalAnalysis traverses the AIL graph and collects definitions.

**__init__**(*project*, *func*, *ail_graph*, *sp_tracker*, *bp_as_gpr*, *stackvars*, *tmps*, *func_args*, *functions*, *variable_map=None*, *ail_manager=None*, *start_state_blocks=None*, *flavor=Flavors.DEFAULT_FLAVOR*)

**Parameters**

- **project** (Project)
- **func** (Function)
- **ail_graph** (*networkx.DiGraph[ailment.Block]*)
- **bp_as_gpr** (*bool*)
- **stackvars** (*bool*)
- **tmps** (*bool*)
- **func_args** (*set[ailment.Expr.VirtualVariable]*)
- **functions** (*Callable[[int | str], Function | None] | None*)
- **start_state_blocks** (*set[tuple[int, int]] | None*)
- **flavor** (*str*)

### angr.analyses.decompiler.ssailification.traversal_engine

angr.analyses.decompiler.ssailification.traversal_engine.**offset_sort_key**(*v*)

**Return type**
tuple[int, int, int, int]

**Parameters**
**v** (*tuple[int | None, int]*)

**class** angr.analyses.decompiler.ssailification.traversal_engine.**DefInfo**

Bases: object

Information about a def, or an expression that defines a new SSA variable.

**def_:** *Def*

**kind:** *Kind*

**loc:** *AILCodeLocation*

**variable_offset:** int

**variable_size:** int

**store_offset:** int

**store_size:** int

**supercedes:** set[*Def*]

**property variable_range**

**property variable_endoffset**

**__init__**(*def_*, *kind*, *loc*, *variable_offset*, *variable_size*, *store_offset*, *store_size*, *supercedes*)

**Parameters**

- **def_** (Def)
- **kind** (Kind)
- **loc** (AILCodeLocation)
- **variable_offset** (*int*)
- **variable_size** (*int*)
- **store_offset** (*int*)
- **store_size** (*int*)
- **supercedes** (*set[Def]*)

**Return type**
None

**class** angr.analyses.decompiler.ssailification.traversal_engine.**SimEngineSSATraversal**

Bases: *SimEngineLightAIL*[*TraversalState*, , None, None]

This engine collects all register and stack variable locations and links them to the block of their creation.

**__init__**(*project*, *simos*, *sp_tracker=None*, *bp_as_gpr=False*, *stackvars=False*, *use_tmps=False*, *functions=None*, *variable_map=None*, *ail_manager=None*, *flavor=Flavors.DEFAULT_FLAVOR*)

**Parameters**

- **project** (Project)
- **bp_as_gpr** (*bool*)
- **stackvars** (*bool*)
- **use_tmps** (*bool*)
- **functions** (Callable[[*int* | *str*], Function | *None*] | *None*)
- **flavor** (*str*)

**variable_map:** *VariableMap* | None

**clobber_defs_by_loc:** dict[tuple[int, int, int], list[*Register*]]

**def_info:** dict[*Def*, *DefInfo*]

**pending_ptr_defines_nonlocal:** dict[int, tuple[*AILCodeLocation*, *StackBaseOffset*, set[tuple[int, int]], bool, bool]]

**hclb_side_exit_state:** *TraversalState* | None

**finalize**()

**perform_def**(*kind*, *def_*, *variable_offset*, *variable_size*, *store_offset*, *store_size*, *loc=None*, *supercedes=None*)

**Parameters**

- **kind** (Kind)
- **def_** (Def)
- **variable_offset** (*int*)
- **variable_size** (*int*)
- **store_offset** (*int*)
- **store_size** (*int*)
- **loc** (AILCodeLocation | *None*)
- **supercedes** (*Iterable[Def] | None*)

**stackvar_get**(*base_offset*, *extra_offset*, *base_size*)

**Return type**

**Parameters**

- **base_offset** (*int*)
- **extra_offset** (*int*)
- **base_size** (*int*)

**stackvar_set**(*base_offset*, *extra_offset*, *base_size*, *value*)

**Parameters**

- **base_offset** (*int*)
- **extra_offset** (*int*)
- **base_size** (*int*)
- **value** (Value)

**register_get**(*offset*, *size*, *def_*)

**Return type**

**Parameters**

- **offset** (*int*)
- **size** (*int*)
- **def_** (Def | *None*)

**clobber_def_for**(*loc*, *reg_offset*)

The definition that the call at `loc` created for the register containing `reg_offset`, if a read of that register ever reached back to this call.

**Return type**

*Register* | None

**Parameters**

- **loc** (AILCodeLocation)
- **reg_offset** (*int*)

**register_set**(*offset*, *size*, *value*, *def_*)

**Parameters**

- **offset** (*int*)
- **size** (*int*)
- **value** (Value)
- **def_** (Def)

### angr.analyses.decompiler.ssailification.traversal_state

**type** angr.analyses.decompiler.ssailification.traversal_state.**Value** = **set**[**tuple**[**int** | **None**, **int**]]

angr.analyses.decompiler.ssailification.traversal_state.**has_conflicting_value_types**(*vs*)

Value contains two types of entries: `(int, *)` that indicates a stack offset, and `(None, int)` that indicates a constant value. This method returns True if a set of Values contains both types of entries, otherwise False.

**Return type**
bool

**Parameters**
**vs** (Value)

**class** angr.analyses.decompiler.ssailification.traversal_state.**TraversalState**

Bases: object

The abstract state for the traversal engine.

**__init__**(*arch*, *func*, *live_registers=None*, *live_stackvars=None*, *register_blackout=None*, *live_vvars=None*, *stackvar_bases=None*, *register_bases=None*, *stackvar_defs=None*, *register_defs=None*, *pending_ptr_defines_nonlocal_live=None*)

**Parameters**

- **live_registers** (*MutableMapping[int, Value] | None*)
- **live_stackvars** (DefaultChainMapCOW[*int*, Value] | *None*)
- **register_blackout** (*Mapping[int, frozenset[AILCodeLocation]] | None*)
- **live_vvars** (DefaultChainMapCOW[*int*, Value] | *None*)
- **stackvar_bases** (IntervalMapCOW[*tuple[int, int]] | None*)
- **register_bases** (*MutableMapping[int, tuple[int, int]] | None*)
- **stackvar_defs** (IntervalMapCOW[*set[Def]] | None*)
- **register_defs** (*MutableMapping[int, set[Def]] | None*)
- **pending_ptr_defines_nonlocal_live** (*set[int] | None*)

**stackvar_unify**(*offset*, *size*)

**Return type**
tuple[int, int, set[int]]

**Parameters**

- **offset** (*int*)
- **size** (*int*)

**register_unify**(*offset*, *size*)

**Return type**
tuple[int, int, set[int]]

**Parameters**

- **offset** (*int*)
- **size** (*int*)

**copy**()

**Return type**
*TraversalState*

**merge**(**others*)

**Return type**
bool

**Parameters**
**others** (TraversalState)

### angr.analyses.decompiler.stack_item

**class** angr.analyses.decompiler.stack_item.**StackItemType**

Bases: Enum

Enum for the type of stack items.

**UNKNOWN = 0**

**SAVED_BP = 1**

**SAVED_REGS = 2**

**ARGUMENT = 3**

**RET_ADDR = 4**

**STACK_CANARY = 5**

**class** angr.analyses.decompiler.stack_item.**StackItem**

Bases: object

A stack item describes a piece of data that is stored on the stack at a certain offset (usually negative).

**__init__**(*offset*, *size*, *name*, *item_type=StackItemType.UNKNOWN*)

**Parameters**

- **offset** (*int*)

- **size** (*int*)
- **name** (*str*)
- **item_type** (StackItemType)

**offset:** int

**size:** int

**name:** str

**item_type:** *StackItemType*

### angr.analyses.decompiler.stackarg_offset_manager

**class** angr.analyses.decompiler.stackarg_offset_manager.**StackArgOffsetManager**

Bases: object

A manager that keeps track of stack argument offsets and sizes for all call sites in a function. This manager also keeps track of the stack virtual variables that can be eliminated for each call site because they are stack arguments.

*all_stackarg_vvars* and *stackoff_to_vvars* map stack arguments to virtual variable IDs. You must call *update_stackoff_vvars()* to populate these two attributes after Stage 1 SSA rewriting. *is_stackarg_vvar()* is only valid after *update_stackoff_vvars()* is called.

**__init__**(*bits*)

**Parameters**
**bits** (*int*)

**add_call_stack_arg_offset**(*block_addr*, *block_idx*, *ins_addr*, *stack_arg_offset*, *stack_arg_size*)

**Parameters**

- **block_addr** (*int*)
- **block_idx** (*int*)
- **ins_addr** (*int*)
- **stack_arg_offset** (*int*)
- **stack_arg_size** (*int*)

**merge**(*other*)

**Parameters**
**other** (StackArgOffsetManager)

**get_stackarg_offsets**()

**Return type**
set[int]

**get_stackarg_insaddrs**()

**Return type**
set[int]

**update_stackoff_vvars**(*rd*)

**Return type**
None

**Parameters**
**rd** (SRDAModel)

**is_stackarg_vvar**(*vvar_id*)

**Return type**
bool

**Parameters**
**vvar_id** (*int*)

### angr.analyses.decompiler.stl_field_accessors

Named accessors for fields of the C++ STL classes registered in the `cpp::std` `SimTypeCollection`.

The KnownPattern machinery (see *angr.analyses.decompiler.known_patterns*) recognizes inlined STL idioms structurally, before variable recovery, and outlines them into calls such as `std::string::length(s)`. That approach has a hard floor: the smallest accessors compile to a single word-sized load at a fixed offset. `std::string::c_str()` on libstdc++ is exactly `mov (%rcx), %rcx`, byte-identical to `std::vector<T>::data()`, `unique_ptr::get()`, and every other pointer-field dereference in the program. No structural pattern can tell them apart, and one that tried would fire on unrelated code constantly.

The information that does distinguish them only exists later: once an anchor pattern (`length`/`capacity`/`empty`/...) has fired anywhere in the function, Typehoon types the container pointer as the corresponding `cpp::std` class, and every other access to it is resolved to a named field. Naming those accesses after their accessors adds no guess of its own. It inherits exactly the confidence of the recovered type, so it can never fire on a pointer that type inference did not already call an STL container, and it does inherit a wrong type: where an anchor pattern mistyped the container, the accessor name is wrong in the same way the field name was.

This module holds the field -> accessor table used to name those already-typed accesses. Only fields whose value is the accessor's return value are listed:

- `m_capacity` is libstdc++'s `_M_allocated_capacity`, which is the active member of a union only for heap-allocated strings, so a raw read of it is not `capacity()`.
- `m_end_of_storage` has no accessor of its own (`capacity()` is a subtraction), so it is not listed either.

angr.analyses.decompiler.stl_field_accessors.**stl_accessor_name**(*ty*, *field_name*)

Return the fully qualified accessor name for reading `field_name` out of `ty`, e.g. `"std::string::c_str"` for the `m_data` field of `std::string`, or `None` when `ty` is not a registered `cpp::std` class or the field has no equivalent accessor.

The lookup is keyed on `SimCppClass.unique_name` and additionally requires that name to be registered in the `cpp::std` type collection, so a user-defined struct that happens to have a field called `m_data` can never match.

**Return type**
str | None

**Parameters**

- **ty** (SimType)
- **field_name** (*str*)

### angr.analyses.decompiler.structured_codegen

class angr.analyses.decompiler.structured_codegen.**BaseStructuredCodeGenerator**

Bases: object

**__init__**(*flavor=None*, *notes=None*, *expr_comments=None*, *stmt_comments=None*, *const_formats=None*)

**map_ast_to_pos:** dict[*SimVariable*, set[*PositionMappingElement*]] | None

**expr_comments:** dict[int, str]

**stmt_comments:** dict[int, str]

**const_formats:** dict[tuple[int, int, str], dict[str, bool]]

**version:** str

**timestamp:** int

**ident_counters:** dict[str, count]

**static adjust_mapping_positions**(*offset*, *pos_to_node*, *pos_to_addr*, *addr_to_pos*)

Adjust positions in the mappings to account for the notes that are prepended to the text.

**Parameters**

- **offset** (int) – The length of the notes to prepend.
- **pos_to_node** (*PositionMapping*) – The position to node mapping.
- **pos_to_addr** (*PositionMapping*) – The position to address mapping.
- **addr_to_pos** (*InstructionMapping*) – The address to position mapping.

**Return type**
tuple[*PositionMapping*, *PositionMapping*, *InstructionMapping*]

**Returns**
Adjusted mappings.

**reapply_options**(*options*)

**regenerate_text**()

**Return type**
None

**reload_variable_types**()

**Return type**
None

**next_ident**(*key*)

**Return type**
str

**Parameters**
**key** (*str*)

**reset_ident_counters**()

**Return type**
None

**next_node_idx**()

**Return type**
int

class angr.analyses.decompiler.structured_codegen.**BinaryOpNode**

Bases: *CodegenNode*

class angr.analyses.decompiler.structured_codegen.**CStructuredCodeGenerator**

Bases: *BaseStructuredCodeGenerator*, *Analysis*, *Serializable*

**__init__**(*func*, *sequence*, *indent=0*, *cfg=None*, *func_args=None*, *binop_depth_cutoff=16*, *show_casts=True*, *braces_on_own_lines=True*, *use_compound_assignments=True*, *show_local_types=True*, *comment_gotos=False*, *cstyle_null_cmp=True*, *flavor=None*, *stmt_comments=None*, *expr_comments=None*, *show_externs=True*, *externs=None*, *const_formats=None*, *show_demangled_name=True*, *show_disambiguated_name=True*, *ail_graph=None*, *simplify_else_scope=True*, *cstyle_ifs=True*, *omit_func_header=False*, *display_block_addrs=False*, *display_vvar_ids=False*, *min_data_addr=4194304*, *notes=None*, *display_notes=True*, *max_str_len=None*, *prettify_thiscall=False*, *cstyle_void_param=True*, *indent_size=4*, *variable_map=None*, *stl_accessor_calls=False*)

**Parameters**

- **func** (Function)
- **func_args** (*list[SimVariable] | None*)
- **binop_depth_cutoff** (*int*)
- **min_data_addr** (*int*)
- **display_notes** (*bool*)
- **max_str_len** (*int | None*)
- **prettify_thiscall** (*bool*)
- **cstyle_void_param** (*bool*)
- **indent_size** (*int*)
- **variable_map** (VariableMap | *None*)
- **stl_accessor_calls** (*bool*)

**ailexpr2cnode:** dict[tuple[*Expression*, bool], *CExpression*] | None

**cnode2ailexpr:** dict[*CExpression*, *Expression*] | None

**map_ast_to_pos:** dict[*SimVariable*, set[*PositionMappingElement*]] | None

**map_addr_to_label:** dict[tuple[int, int | None], *CLabel*]

**cfunc:** *CFunction* | None

**cexterns:** set[*CVariable*] | None

**reapply_options**(*options*)

**cleanup**()

Remove existing rendering results.

**regenerate_text**()

Re-render text and re-generate all sorts of mapping information.

**Return type**
None

**render_text**(*cfunc*)

**Return type**

**Parameters**
**cfunc** (CFunction)

**render_notes**()

Render decompilation notes.

**Return type**
str

**Returns**
A string containing all notes.

**reload_variable_types**()

**Return type**
None

**default_simtype_from_bits**(*n*, *signed=True*)

**Return type**
*SimType*

**Parameters**

- **n** (*int*)
- **signed** (*bool*)

**variables_unify**(*v1*, *v2*)

**Return type**
bool

**Parameters**

- **v1** (VirtualVariable)
- **v2** (VirtualVariable)

**ERRNO_LOCATION_FUNCS = frozenset({'__errno', '__errno_location', '__error', '_errno'})**

The libc functions that return `&errno`. `errno` is a macro that dereferences one of them, so it never survives into a binary as a symbol; what reaches decompilation is `*(__errno_location())`, which is both correct and unreadable.

**class** angr.analyses.decompiler.structured_codegen.**CStructuredCodeWalker**

Bases: object

**handle**(*obj*)

**handle_default**(*obj*)

**handle_CFunction**(*obj*)

**handle_CDirtyExpression**(*obj*)

**class** angr.analyses.decompiler.structured_codegen.**ClosingObjectNode**

Bases: *CodegenNode*

A closing bracket, brace, or parenthesis.

**class** angr.analyses.decompiler.structured_codegen.**CodegenNode**

Bases: `object`

Marker base of every structured-codegen node kind shared across flavors.

**class** angr.analyses.decompiler.structured_codegen.**ConstantNode**

Bases: *CodegenNode*

A constant; has `value` and `reference_values`.

class angr.analyses.decompiler.structured_codegen.**DummyStructuredCodeGenerator**

Bases: *BaseStructuredCodeGenerator*, *Serializable*

A dummy structured code generator that only stores user-specified information.

**__init__**(*flavor*, *expr_comments=None*, *stmt_comments=None*, *configuration=None*, *const_formats=None*)

**Parameters**
**flavor** (*str*)

class angr.analyses.decompiler.structured_codegen.**ExpressionNode**

Bases: *CodegenNode*

class angr.analyses.decompiler.structured_codegen.**FunctionCallNode**

Bases: *CodegenNode*

A call; has `callee_func` (a Function or None) and `callee_target`.

class angr.analyses.decompiler.structured_codegen.**FunctionNode**

Bases: *CodegenNode*

The function being decompiled; has `addr` and `name`.

class angr.analyses.decompiler.structured_codegen.**GoStructuredCodeGenerator**

Bases: *BaseStructuredCodeGenerator*, *Analysis*, *Serializable*

**__init__**(*func*, *sequence*, *indent=0*, *cfg=None*, *func_args=None*, *binop_depth_cutoff=16*, *show_casts=True*, *braces_on_own_lines=False*, *use_compound_assignments=True*, *show_local_types=True*, *comment_gotos=False*, *cstyle_null_cmp=True*, *flavor=None*, *stmt_comments=None*, *expr_comments=None*, *show_externs=True*, *externs=None*, *const_formats=None*, *show_demangled_name=True*, *show_disambiguated_name=True*, *ail_graph=None*, *simplify_else_scope=True*, *cstyle_ifs=True*, *omit_func_header=False*, *display_block_addrs=False*, *display_vvar_ids=False*, *min_data_addr=4194304*, *notes=None*, *display_notes=True*, *max_str_len=None*, *prettify_thiscall=False*, *cstyle_void_param=True*, *indent_size=4*, *variable_map=None*, *stl_accessor_calls=False*)

**Parameters**

- **func_args** (*list[SimVariable] | None*)
- **binop_depth_cutoff** (*int*)
- **min_data_addr** (*int*)
- **display_notes** (*bool*)
- **max_str_len** (*int | None*)
- **prettify_thiscall** (*bool*)
- **cstyle_void_param** (*bool*)
- **indent_size** (*int*)
- **variable_map** (*VariableMap | None*)
- **stl_accessor_calls** (*bool*)

**reapply_options**(*options*)

**cleanup**()

Remove existing rendering results.

**regenerate_text**()

Re-render text and re-generate all sorts of mapping information.

**Return type**
None

**render_text**(*cfunc*)

**Return type**

**Parameters**
**cfunc** (GoFunction)

**render_notes**()

Render decompilation notes.

**Return type**
str

**Returns**
A string containing all notes.

**reload_variable_types**()

**Return type**
None

**default_simtype_from_bits**(*n*, *signed=True*)

**Return type**
*SimType*

**Parameters**

- **n** (*int*)
- **signed** (*bool*)

**variables_unify**(*v1*, *v2*)

**Return type**
bool

**Parameters**

- **v1** (VirtualVariable)
- **v2** (VirtualVariable)

**property map_ast_to_pos:** dict[Any, set[*PositionMappingElement*]] | None

**resolve_callee**(*addr*)

The function at addr for a parsed call, the same object for every call to it.

**Return type**
*Function* | None

**Parameters**
**addr** (*int*)

**class** angr.analyses.decompiler.structured_codegen.**ImportSourceCode**

Bases: *BaseStructuredCodeGenerator*, *Analysis*

__init__(*function*, *flavor='source'*, *source_root=None*, *encoding='utf-8'*)

- **indent_size** (*int*)
- **variable_map** (*VariableMap | None*)
- **stl_accessor_calls** (*bool*)

**reapply_options**(*options*)

**cleanup**()

Remove existing rendering results.

**regenerate_text**()

Re-render text and re-generate all sorts of mapping information.

**Return type**
None

**RENDER_TYPE**

alias of tuple[str, *PositionMapping*, *PositionMapping*, *InstructionMapping*, dict[Any, set[Any]]]

**render_text**(*rust_func*)

**Return type**
tuple[str, *PositionMapping*, *PositionMapping*, *InstructionMapping*, dict[Any, set[Any]]]

**Parameters**
**rust_func** (RustFunction)

**render_notes**()

Render decompilation notes.

**Return type**
str

**Returns**
A string containing all notes.

**reload_variable_types**()

**Return type**
None

**default_simtype_from_size**(*n*, *signed=True*)

**Return type**
*RustSimTypeInt*

**Parameters**

- **n** (*int*)
- **signed** (*bool*)

**class** angr.analyses.decompiler.structured_codegen.**StructFieldNode**

Bases: *CodegenNode*

A struct field name; has `struct_type`, `offset`, and `field`.

**class** angr.analyses.decompiler.structured_codegen.**UnaryOpNode**

Bases: *CodegenNode*

**class** angr.analyses.decompiler.structured_codegen.**VariableFieldNode**

Bases: *CodegenNode*

**class** angr.analyses.decompiler.structured_codegen.**VariableNode**

Bases: *CodegenNode*

A variable access; has `variable` and `unified_variable`.

| *sse_intrinsics* | Intel-intrinsics view of 128-bit SSE vector AIL: lane kinds of variables, _mm_* names of lane-wise ops, and the pshufd lane shuffles that VEX spells out as CONCAT trees of 32-bit lane extractions. |
| *utils* | |

### angr.analyses.decompiler.structured_codegen.base

**class** angr.analyses.decompiler.structured_codegen.base.**CConstantType**

Bases: Enum

Describes the value type of a CConstant class.

**INT = 0**

**FLOAT = 1**

**STRING = 2**

**class** angr.analyses.decompiler.structured_codegen.base.**FunctionRef**

Bases: object

A function a parsed decompilation refers to, carried by address until it is first needed, so that parsing a decompilation does not load functions.

**__init__**(*addr*)

**Parameters**
**addr** (*int*)

**addr**

**class** angr.analyses.decompiler.structured_codegen.base.**PositionMappingElement**

Bases: object

**__init__**(*start*, *length*, *obj*)

**start:** int

**length:** int

**obj**

**class** angr.analyses.decompiler.structured_codegen.base.**PositionMapping**

Bases: object

**DUPLICATION_CHECK = True**

**__init__**()

**items**()

**values**()

**add_mapping**(*start_pos*, *length*, *obj*)

**get_node**(*pos*)

**Parameters**
**pos** (*int*)

**get_element**(*pos*)

**Return type**
*PositionMappingElement* | None

**Parameters**
**pos** (*int*)

**class** angr.analyses.decompiler.structured_codegen.base.**InstructionMappingElement**

Bases: object

**__init__**(*ins_addr*, *posmap_pos*)

**ins_addr:** int

**posmap_pos:** int

**class** angr.analyses.decompiler.structured_codegen.base.**InstructionMapping**

Bases: object

**__init__**()

**items**()

**values**()

**add_mapping**(*ins_addr*, *posmap_pos*)

**get_nearest_pos**(*ins_addr*)

**Return type**
int | None

**Parameters**
**ins_addr** (*int*)

**class** angr.analyses.decompiler.structured_codegen.base.**BaseStructuredCodeGenerator**

Bases: object

**__init__**(*flavor=None*, *notes=None*, *expr_comments=None*, *stmt_comments=None*, *const_formats=None*)

**map_ast_to_pos:** dict[*SimVariable*, set[*PositionMappingElement*]] | None

**expr_comments:** dict[int, str]

**stmt_comments:** dict[int, str]

**const_formats:** dict[tuple[int, int, str], dict[str, bool]]

**version:** str

**timestamp:** int

**ident_counters:** dict[str, count]

**static adjust_mapping_positions**(*offset*, *pos_to_node*, *pos_to_addr*, *addr_to_pos*)

Adjust positions in the mappings to account for the notes that are prepended to the text.

**Parameters**

- **offset** (int) – The length of the notes to prepend.
- **pos_to_node** (*PositionMapping*) – The position to node mapping.
- **pos_to_addr** (*PositionMapping*) – The position to address mapping.
- **addr_to_pos** (*InstructionMapping*) – The address to position mapping.

**Return type**
tuple[*PositionMapping*, *PositionMapping*, *InstructionMapping*]

**Returns**
Adjusted mappings.

**reapply_options**(*options*)

**regenerate_text**()

**Return type**
None

**reload_variable_types**()

**Return type**
None

**next_ident**(*key*)

**Return type**
str

**Parameters**
**key** (*str*)

**reset_ident_counters**()

**Return type**
None

**next_node_idx**()

**Return type**
int

angr.analyses.decompiler.structured_codegen.base.**vector_convert_name**(*expr*)

Intrinsic-style name for a lane-wise conversion, e.g. ConvF32toI32Sx4 for Iop_F32toI32Sx4.

**Return type**
str

**Parameters**
**expr** (Convert)

angr.analyses.decompiler.structured_codegen.base.**variable_display_name**(*v*)

The name of a variable that variable naming did not reach (e.g. a stack variable not in any unified group), as an identifier rather than the SimVariable repr.

**Return type**
str

**Parameters**
**v** (SimVariable)

angr.analyses.decompiler.structured_codegen.base.**register_display_name**(*arch*, *reg_offset*, *size*)
The architectural name of a register, or reg_<offset> when the architecture has none.

**Return type**
str

**Parameters**
- **arch** (*archinfo.Arch*)
- **reg_offset** (*int*)
- **size** (*int*)

**class** angr.analyses.decompiler.structured_codegen.base.**CodegenNode**
Bases: object

Marker base of every structured-codegen node kind shared across flavors.

**class** angr.analyses.decompiler.structured_codegen.base.**ExpressionNode**
Bases: *CodegenNode*

**class** angr.analyses.decompiler.structured_codegen.base.**VariableNode**
Bases: *CodegenNode*

A variable access; has variable and unified_variable.

**class** angr.analyses.decompiler.structured_codegen.base.**IndexedVariableNode**
Bases: *CodegenNode*

**class** angr.analyses.decompiler.structured_codegen.base.**VariableFieldNode**
Bases: *CodegenNode*

**class** angr.analyses.decompiler.structured_codegen.base.**StructFieldNode**
Bases: *CodegenNode*

A struct field name; has struct_type, offset, and field.

**class** angr.analyses.decompiler.structured_codegen.base.**FunctionNode**
Bases: *CodegenNode*

The function being decompiled; has addr and name.

**class** angr.analyses.decompiler.structured_codegen.base.**FunctionCallNode**
Bases: *CodegenNode*

A call; has callee_func (a Function or None) and callee_target.

**class** angr.analyses.decompiler.structured_codegen.base.**ConstantNode**
Bases: *CodegenNode*

A constant; has value and reference_values.

**class** angr.analyses.decompiler.structured_codegen.base.**LabelNode**
Bases: *CodegenNode*

**class** angr.analyses.decompiler.structured_codegen.base.**BinaryOpNode**
Bases: *CodegenNode*

class angr.analyses.decompiler.structured_codegen.base.**UnaryOpNode**

Bases: *CodegenNode*

class angr.analyses.decompiler.structured_codegen.base.**ClosingObjectNode**

Bases: *CodegenNode*

A closing bracket, brace, or parenthesis.

### angr.analyses.decompiler.structured_codegen.c

type angr.analyses.decompiler.structured_codegen.c.**RenderResult** = tuple[str, *PositionMapping*, *PositionMapping*, *InstructionMapping*, dict[Any, set[Any]]]

angr.analyses.decompiler.structured_codegen.c.**qualifies_for_simple_cast**(*ty1*, *ty2*)

angr.analyses.decompiler.structured_codegen.c.**qualifies_for_width_cast**(*ty*)

angr.analyses.decompiler.structured_codegen.c.**int_width_and_signedness**(*ty*)

The (bits, signed) of an integer-like C type, or None when the type is not an integer or has no size.

**Return type**
tuple[int, bool] | None

**Parameters**
**ty** (SimType | *None*)

angr.analyses.decompiler.structured_codegen.c.**int_operand_signedness**(*expr*)

The signedness of an integer expression as C reads it. Constants are neutral (None): an int literal does not make (int)a - 1 unsigned, even though the common type the codegen computes for it is.

**Return type**
bool | None

**Parameters**
**expr** (CExpression)

angr.analyses.decompiler.structured_codegen.c.**is_sign_fixing_cast**(*cast*)

A same-width integer cast whose operand C reads with the other signedness, e.g. (long long)x for unsigned x.

**Return type**
bool

**Parameters**
**cast** (CTypeCast)

angr.analyses.decompiler.structured_codegen.c.**qualifies_for_implicit_cast**(*ty1*, *ty2*)

angr.analyses.decompiler.structured_codegen.c.**c_return_type**(*returnty*)

Convert a return type to a C-compatible type. - Arrays are converted to pointers to their element type.

**Return type**
*SimType*

**Parameters**
**returnty** (SimType)

angr.analyses.decompiler.structured_codegen.c.**extract_terms**(*expr*)

**Return type**
tuple[int, list[tuple[int, *CExpression*]]]

**Parameters**
**expr** (CExpression)

angr.analyses.decompiler.structured_codegen.c.**is_machine_word_size_type**(*type_*, *arch*)

**Return type**
bool

**Parameters**

- **type_** (SimType)
- **arch** (*archinfo.Arch*)

angr.analyses.decompiler.structured_codegen.c.**guess_value_type**(*value*, *project*)

**Return type**
*SimType* | None

**Parameters**

- **value** (*int*)
- **project** (*angr.Project*)

angr.analyses.decompiler.structured_codegen.c.**type_equals**(*t0*, *t1*)

**Return type**
bool

**Parameters**

- **t0** (SimType)
- **t1** (SimType)

angr.analyses.decompiler.structured_codegen.c.**type_layout_key**(*ty*, *memo=None*)

A structural sort key for a type, derived purely from its memory layout (sizes, field offsets, and the layouts of field/element/pointee types) and not from any user-renamable struct or field name. This lets the code generator order type definitions stably without their order changing when the user renames a struct or a field.

The key covers the type down to TYPE_LAYOUT_KEY_DEPTH levels of struct nesting. The key summarizes the member of each struct level in a hash.

**Return type**
str

**Parameters**
**memo** (*_LayoutKeyMemo | None*)

angr.analyses.decompiler.structured_codegen.c.**cextern_sort_key**(*cextern*)

A stable sort key for extern variables, based on the variable's address. Unlike the variable name, the address does not change when the user renames the variable, so the ordering of extern definitions stays put across renames.

**Return type**
tuple

angr.analyses.decompiler.structured_codegen.c.**type_to_c_repr_chunks**(*ty*, *name=None*, *name_type=None*, *full=False*, *indent_str=''*, *indent_delta=4*, *memo=None*)

Helper generator function to turn a SimType into generated tuples of (C-string, AST node).

**Parameters**

- **indent_delta** (int) – Number of space characters used to indent each struct field one level deeper.
- **memo** (set[int] | None) – IDs of the aggregates currently being rendered further up the stack, so that a self-referential type is elided instead of recursed into. An aggregate is added before its members are rendered and removed once they are done.
- **ty** (SimType)

class angr.analyses.decompiler.structured_codegen.c.**CConstruct**

Bases: object

Represents a program construct in C. Acts as the base class for all other representation constructions.

**__init__**(*codegen*, *tags=None*)

**Parameters**
**codegen** (CStructuredCodeGenerator)

**tags**

**codegen:** *CStructuredCodeGenerator*

**ident:** str

**idx:** int

**c_repr**(*initial_pos=0*, *indent=0*, *pos_to_node=None*, *pos_to_addr=None*, *addr_to_pos=None*)

Creates the C representation of the code and displays it by constructing a large string. This function is called by each program function that needs to be decompiled. The map_pos_to_node and map_pos_to_addr act as position maps for the location of each variable and statement to be tracked for later GUI operations. The map_pos_to_addr also contains expressions that are nested inside of statements.

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**static indent_str**(*indent=0*)

class angr.analyses.decompiler.structured_codegen.c.**CFunction**

Bases: *CConstruct*, *FunctionNode*

Represents a function in C.

**__init__**(*addr*, *name*, *functy*, *arg_list*, *statements*, *variables_in_use*, *variable_manager*, *demangled_name=None*, *show_demangled_name=True*, *omit_header=False*, ***kwargs*)

**Parameters**

- **addr** (*int*)
- **name** (*str*)
- **functy** (SimTypeFunction)
- **arg_list** (*list[CVariable]*)
- **statements** (CStatements)

**addr**

**name**

**functy**

**arg_list**

**statements**

**variables_in_use**

**variable_manager:** *VariableManagerInternal*

**demangled_name**

**unified_local_vars:** dict[*SimVariable*, list[tuple[*CVariable*, *SimType*]]]

**show_demangled_name**

**omit_header**

**refresh**()

**get_unified_local_vars**()

**Return type**
dict[*SimVariable*, list[tuple[*CVariable*, *SimType*]]]

**variable_list_repr_chunks**(*indent=0*)

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**headerless_c_repr_chunks**(*indent=0*)

**full_c_repr_chunks**(*indent=0*, *asexpr=False*)

**static sort_local_vars**(*local_vars*)

**Return type**
list[*SimVariable*]

**Parameters**
**local_vars** (*Iterable*[SimVariable])

**class** angr.analyses.decompiler.structured_codegen.c.**CStatement**

Bases: *CConstruct*

Represents a statement in C.

**__init__**(*tags=None*, ***, *codegen*)

**Parameters**
**codegen** (CStructuredCodeGenerator)

**codegen:** *CStructuredCodeGenerator*

**ident:** str

**idx:** int

**tags**

class angr.analyses.decompiler.structured_codegen.c.**CExpression**

Bases: *CConstruct*, *ExpressionNode*

Base class for C expressions.

**__init__**(*collapsed=False*, *tags=None*, ***, *codegen*)

**Parameters**
**codegen** (CStructuredCodeGenerator)

**collapsed**

**property type:** *SimType* | None

**set_type**(*v*)

class angr.analyses.decompiler.structured_codegen.c.**CStatements**

Bases: *CStatement*

Represents a sequence of statements in C.

**__init__**(*statements*, *addr=None*, ***kwargs*)

**Parameters**
**statements** (*Sequence*[CStatement])

**statements**

**addr**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.c.**CAILBlock**

Bases: *CStatement*

Represents a block of AIL statements.

**__init__**(*block*, ***kwargs*)

**Parameters**
**block** (*Block*)

**block**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.c.**CLoop**

Bases: *CStatement*

Represents a loop in C.

class angr.analyses.decompiler.structured_codegen.c.**CWhileLoop**

Bases: *CLoop*

Represents a while loop in C.

**__init__**(*condition*, *body*, ***kwargs*)

**Parameters**

- **condition** (CExpression | *None*)
- **body** (CStatements | *None*)

**condition**

**body**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.c.**CDoWhileLoop**

Bases: *CLoop*

Represents a do-while loop in C.

**__init__**(*condition*, *body*, ***kwargs*)

**Parameters**

- **condition** (*CExpression | None*)
- **body** (*CStatements | None*)

**condition**

**body**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.c.**CForLoop**

Bases: *CStatement*

Represents a for-loop in C.

**__init__**(*initializer*, *condition*, *iterator*, *body*, ***kwargs*)

**Parameters**

- **condition** (*CExpression | None*)
- **body** (*CStatements | None*)

**initializer**

**condition**

**iterator**

**body**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.c.**CIfElse**

Bases: *CStatement*

Represents an if-else construct in C.

**__init__**(*condition_and_nodes*, *else_node=None*, *simplify_else_scope=False*, *cstyle_ifs=True*, ***kwargs*)

**Parameters**

- **condition_and_nodes** (*list[tuple[CExpression, CStatement | None]]*)
- **else_node** (*CStatements | None*)

**condition_and_nodes**

**else_node**

**simplify_else_scope**

**cstyle_ifs**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.c.**CIfBreak**

Bases: *CStatement*

Represents an if-break statement in C.

**__init__**(*condition*, *cstyle_ifs=True*, ***kwargs*)

**Parameters**
**condition** (CExpression)

**condition**

**cstyle_ifs**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.c.**CBreak**

Bases: *CStatement*

Represents a break statement in C.

**__init__**(***kwargs*)

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.c.**CContinue**

Bases: *CStatement*

Represents a continue statement in C.

**__init__**(***kwargs*)

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.c.**CSwitchCase**

Bases: *CStatement*

Represents a switch-case statement in C.

**__init__**(*switch*, *cases*, *default*, ***kwargs*)

**Parameters**
**switch** (CExpression)

**switch**

**cases:** list[tuple[int | tuple[int], *CStatements*]]

**default**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.c.**CIncompleteSwitchCase**

Bases: *CStatement*

Represents an incomplete switch-case construct; this only appear in the decompilation output when switch-case structuring fails (for whatever reason).

__init__(*head*, *cases*, ***kwargs*)

head

cases: list[tuple[int, CStatements]]

c_repr_chunks(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.c.CAssignment

Bases: CStatement

a = b

__init__(*lhs*, *rhs*, ***kwargs*)

**Parameters**
**rhs** (CExpression)

lhs

rhs

c_repr_chunks(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.c.CExpressionStatement

Bases: CStatement

Wraps a CExpression so it can be used as a standalone statement.

expr;

__init__(*expr*, *returning=True*, ***kwargs*)

**Parameters**

- **expr** (CExpression)
- **returning** (*bool*)

expr

returning

c_repr_chunks(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.c.CFunctionCall

Bases: CExpression, FunctionCallNode

func(arg0, arg1)

**Variables**
**callee_func** (Function) – The function getting called.

__init__(*callee_target*, *callee_func*, *args*, *show_demangled_name=True*, *show_disambiguated_name=True*, *tags=None*, ***, *codegen*, *callsite_prototype=None*, ***kwargs*)

**Parameters**

- **show_disambiguated_name** (*bool*)
- **callsite_prototype** (SimTypeFunction | *None*)

callee_target

**callee_func:** *Function* | None

**callsite_prototype**

**args**

**show_demangled_name**

**show_disambiguated_name**

**property prettify_thiscall:** bool

**property prototype:** *SimTypeFunction* | None

**property prototype_returnty:** *SimType*

Returns returnty and avoids creating the SimTypeFunction instance if the function prototype is not available. Instead of self.prototype.returnty, you should use self.prototype_returnty for better performance.

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.c.**CReturn**

Bases: *CStatement*

**__init__**(*retval*, ***kwargs*)

**Parameters**

**retval** (*CExpression | None*)

**retval**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.c.**CGoto**

Bases: *CStatement*

**__init__**(*target*, *target_idx*, ***kwargs*)

**Parameters**

- **target** (*CExpression | int*)
- **target_idx** (*int*)

**target:** int | *CExpression*

**target_idx**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.c.**CUnsupportedStatement**

Bases: *CStatement*

A wrapper for unsupported AIL statement.

**__init__**(*stmt*, ***kwargs*)

**stmt**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.c.**CDirtyStatement**

Bases: *CExpression*

**__init__**(*dirty*, ***kwargs*)

**Parameters**
**dirty** (CDirtyExpression)

**dirty**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.c.**CLabel**

Bases: *CStatement*, *LabelNode*

Represents a label in C code.

**__init__**(*name*, ***kwargs*)

**Parameters**
**name** (*str*)

**name**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.c.**CStructField**

Bases: *CExpression*, *StructFieldNode*

**__init__**(*struct_type*, *offset*, *field*, ***kwargs*)

**Parameters**

- **struct_type** (SimStruct)
- **offset** (*int*)
- **field** (*str*)

**struct_type**

**offset**

**field**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.c.**CFakeVariable**

Bases: *CExpression*

An uninterpreted name to display in the decompilation output. Pretty much always represents an error?

**__init__**(*name*, *ty*, ***kwargs*)

**Parameters**

- **name** (*str*)
- **ty** (SimType)

**name**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.c.**CVariable**

Bases: *CExpression*, *VariableNode*

CVariable represents access to a variable with the specified type (*variable_type*).

*variable* must be a SimVariable.

**__init__**(*variable*, *unified_variable=None*, *variable_type=None*, *vvar_id=None*, ***kwargs*)

**Parameters**
**variable** (SimVariable)

**variable:** *SimVariable*

**unified_variable:** *SimVariable* | None

**variable_type:** *SimType* | None

**vvar_id**

**property type**

**property name**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.c.**CIndexedVariable**

Bases: *CExpression*, *IndexedVariableNode*

Represent a variable (an array) that is indexed.

**__init__**(*variable*, *index*, *variable_type=None*, ***kwargs*)

**Parameters**

- **variable** (CExpression)
- **index** (CExpression)

**index:** *CExpression*

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**collapsed**

class angr.analyses.decompiler.structured_codegen.c.**CVariableField**

Bases: *CExpression*, *VariableFieldNode*

Represent a field of a variable.

**stl_accessor:** str | None = None

**__init__**(*variable*, *field*, *var_is_ptr=False*, ***kwargs*)

**Parameters**

- **variable** (CExpression)
- **field** (CStructField)
- **var_is_ptr** (*bool*)

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**collapsed**

class angr.analyses.decompiler.structured_codegen.c.**CUnaryOp**

Bases: *CExpression*, *UnaryOpNode*

Unary operations.

**__init__**(*op*, *operand*, ***kwargs*)

**Parameters**

- **op** (*str*)
- **operand** (CExpression)

**op**

**operand**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.c.**CBinaryOp**

Bases: *CExpression*, *BinaryOpNode*

Binary operations.

**__init__**(*op*, *lhs*, *rhs*, *signed=None*, ***kwargs*)

**Parameters**

- **op** (*str*)
- **lhs** (CExpression)
- **rhs** (CExpression)
- **signed** (*bool | None*)

**op**

**lhs**

**rhs**

**signed**

**common_type**

**static compute_common_type**(*op*, *lhs_ty*, *rhs_ty*)

**Return type**
*SimType*

**Parameters**

- **op** (*str*)
- **lhs_ty** (SimType)
- **rhs_ty** (SimType)

**property type**

**property op_precedence**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.c.**CTypeCast**

Bases: *CExpression*

**__init__**(*src_type*, *dst_type*, *expr*, ***kwargs*)

**Parameters**

- **src_type** (SimType | *None*)
- **dst_type** (SimType)
- **expr** (CExpression)

**src_type**

**dst_type**

**expr**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

angr.analyses.decompiler.structured_codegen.c.**prefix_unary_operand_needs_parens**(*operand*, *op*)

Whether the operand of the prefix unary operator op must be parenthesized.

Skip operand parentheses after * in the following cases: - **p - *p->q - *a[i] - *(char *)p - !!x

-(-x) and ~(~x) keep their parentheses. Everything else (binops or an expression class with no known precedence) keeps parentheses.

**Return type**
bool

**Parameters**

- **operand** (CExpression)
- **op** (*str*)

angr.analyses.decompiler.structured_codegen.c.**is_addressable_lvalue**(*cexpr*)

Whether the expression names memory: a stack or global variable, an array element, a dereference, or a field of one of those. Register variables and register-held parameters are not.

**Return type**
bool

**Parameters**
**cexpr** (CExpression)

class angr.analyses.decompiler.structured_codegen.c.**CReinterpret**

Bases: *CExpression*

A bit-pattern view of an expression as another type of the same width: `*(T *)&x` for a memory-backed lvalue, `__double_as_longlong(x)` (the CUDA intrinsic names) for register variables and other values.

```
INTRINSICS: dict[tuple[str, int | None, str, int | None], str] = {('F', 32, 'I',
32):  '__float_as_int', ('F', 64, 'I', 64):  '__double_as_longlong', ('I', 32, 'F',
32):  '__int_as_float', ('I', 64, 'F', 64):  '__longlong_as_double'}
```

**__init__**(*src_type*, *dst_type*, *expr*, ***kwargs*)

**Parameters**

- **src_type** (SimType)
- **dst_type** (SimType)
- **expr** (CExpression)

**src_type**

**dst_type**

**expr**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.c.**CConstant**

Bases: *CExpression*, *ConstantNode*

**__init__**(*value*, *type_*, *reference_values=None*, ***kwargs*)

**Parameters**

- **value** (*float | str*)
- **type_** (SimType)
- **reference_values** (*dict[*SimType, *str | bytes | int | float |* Function *|* MemoryData*] | None*)

**value: int | float | str**

**reference_values**

**property fmt**

**property fmt_hex**

**property fmt_neg**

**property fmt_char**

**Setter accepts**
bool

property fmt_float

Setter accepts
bool

property fmt_double

Setter accepts
bool

property type

static str_to_c_str(*_str*, *prefix=''*, *maxlen=None*)

Return type
str

Parameters

- **prefix** (*str*)
- **maxlen** (*int | None*)

c_repr_chunks(*indent=0*, *asexpr=False*)

fmt_int(*value*)

Format an integer using the format setup of the current node.

Parameters
**value** (int) – The integer value to format.

Return type
str

Returns
The formatted string.

class angr.analyses.decompiler.structured_codegen.c.CRegister

Bases: *CExpression*

__init__(*reg*, ***kwargs*)

Parameters
**reg** (*str*)

reg

property type

c_repr_chunks(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.c.CITE

Bases: *CExpression*

__init__(*cond*, *iftrue*, *iffalse*, ***kwargs*)

Parameters

- **cond** (CExpression)
- **iftrue** (CExpression)
- **iffalse** (CExpression)

**cond**

**iftrue**

**iffalse**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.c.**CMultiStatementExpression**

Bases: *CExpression*

(stmt0, stmt1, stmt2, expr)

**__init__**(*stmts*, *expr*, ***kwargs*)

**Parameters**

- **stmts** (CStatements)
- **expr** (CExpression)

**stmts**

**expr**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.c.**CVEXCCallExpression**

Bases: *CExpression*

ccall_name(arg0, arg1, ...)

**__init__**(*callee*, *operands*, ***kwargs*)

**Parameters**

- **callee** (*str*)
- **operands** (*list[CExpression]*)

**callee**

**operands**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.c.**CVectorConvert**

Bases: *CExpression*

A lane-wise conversion (an AIL Convert with vector_count), rendered as an intrinsic-style call because C has no vector cast syntax.

**__init__**(*expr*, *operand*, ***kwargs*)

**Parameters**

- **expr** (Convert)
- **operand** (CExpression)

**expr**

**operand**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.c.**CDirtyExpression**

Bases: *CExpression*

Ideally all dirty expressions should be handled and converted to proper conversions during conversion from VEX to AIL. Eventually this class should not be used at all.

**__init__**(*dirty*, *operands=None*, ***kwargs*)

**Parameters**
**operands** (*list[CExpression] | None*)

**dirty**

**operands**

**property type**

**intrinsic_name**()

Return the dirty callee if it is a clean C identifier, else None.

**Return type**
str | None

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.c.**CClosingObject**

Bases: *ClosingObjectNode*

A class to represent all objects that can be closed by it's correspodning character. Examples: (), {}, []

**__init__**(*opening_symbol*)

**opening_symbol**

**class** angr.analyses.decompiler.structured_codegen.c.**CArrayTypeLength**

Bases: object

A class to represent the type information of fixed-size array lengths. Examples: In "char foo[20]", this would be the "[20]".

**__init__**(*text*)

**text**

**class** angr.analyses.decompiler.structured_codegen.c.**CStructFieldNameDef**

Bases: object

A class to represent the name of a defined field in a struct. Needed because it's not a CVariable or a CStructField (because CStructField is the access of a CStructField). Example: In "struct foo { int bar; }, this would be "bar".

**__init__**(*name*)

**name**

class angr.analyses.decompiler.structured_codegen.c.**CStructuredCodeGenerator**

Bases: *BaseStructuredCodeGenerator*, *Analysis*, *Serializable*

**__init__**(*func*, *sequence*, *indent=0*, *cfg=None*, *func_args=None*, *binop_depth_cutoff=16*, *show_casts=True*, *braces_on_own_lines=True*, *use_compound_assignments=True*, *show_local_types=True*, *comment_gotos=False*, *cstyle_null_cmp=True*, *flavor=None*, *stmt_comments=None*, *expr_comments=None*, *show_externs=True*, *externs=None*, *const_formats=None*, *show_demangled_name=True*, *show_disambiguated_name=True*, *ail_graph=None*, *simplify_else_scope=True*, *cstyle_ifs=True*, *omit_func_header=False*, *display_block_addrs=False*, *display_vvar_ids=False*, *min_data_addr=4194304*, *notes=None*, *display_notes=True*, *max_str_len=None*, *prettify_thiscall=False*, *cstyle_void_param=True*, *indent_size=4*, *variable_map=None*, *stl_accessor_calls=False*)

**Parameters**

- **func** (Function)
- **func_args** (*list[SimVariable] | None*)
- **binop_depth_cutoff** (*int*)
- **min_data_addr** (*int*)
- **display_notes** (*bool*)
- **max_str_len** (*int | None*)
- **prettify_thiscall** (*bool*)
- **cstyle_void_param** (*bool*)
- **indent_size** (*int*)
- **variable_map** (VariableMap | *None*)
- **stl_accessor_calls** (*bool*)

**ailexpr2cnode:** dict[tuple[*Expression*, bool], *CExpression*] | None

**cnode2ailexpr:** dict[*CExpression*, *Expression*] | None

**map_ast_to_pos:** dict[*SimVariable*, set[*PositionMappingElement*]] | None

**map_addr_to_label:** dict[tuple[int, int | None], *CLabel*]

**cfunc:** *CFunction* | None

**cexterns:** set[*CVariable*] | None

**reapply_options**(*options*)

**cleanup**()

Remove existing rendering results.

**regenerate_text**()

Re-render text and re-generate all sorts of mapping information.

**Return type**

None

**render_text**(*cfunc*)

**Return type**

**Parameters**
**cfunc** (CFunction)

**render_notes**()

Render decompilation notes.

**Return type**
str

**Returns**
A string containing all notes.

**reload_variable_types**()

**Return type**
None

**default_simtype_from_bits**(*n*, *signed=True*)

**Return type**
*SimType*

**Parameters**

- **n** (*int*)
- **signed** (*bool*)

**variables_unify**(*v1*, *v2*)

**Return type**
bool

**Parameters**

- **v1** (VirtualVariable)
- **v2** (VirtualVariable)

**ERRNO_LOCATION_FUNCS = frozenset({'__errno', '__errno_location', '__error', '_errno'})**

The libc functions that return `&errno`. `errno` is a macro that dereferences one of them, so it never survives into a binary as a symbol; what reaches decompilation is `*(__errno_location())`, which is both correct and unreadable.

**class** angr.analyses.decompiler.structured_codegen.c.**CStructuredCodeWalker**

Bases: object

**handle**(*obj*)

**handle_default**(*obj*)

**handle_CFunction**(*obj*)

**handle_CStatements**(*obj*)

**handle_CWhileLoop**(*obj*)

**handle_CDoWhileLoop**(*obj*)

**handle_CForLoop**(*obj*)

**handle_CIfElse**(*obj*)

**handle_CIfBreak**(*obj*)

**handle_CSwitchCase**(*obj*)

**handle_CAssignment**(*obj*)

**handle_CExpressionStatement**(*obj*)

**handle_CFunctionCall**(*obj*)

**handle_CReturn**(*obj*)

**handle_CGoto**(*obj*)

**handle_CIndexedVariable**(*obj*)

**handle_CVariableField**(*obj*)

**handle_CUnaryOp**(*obj*)

**handle_CBinaryOp**(*obj*)

**handle_CTypeCast**(*obj*)

**handle_CITE**(*obj*)

**handle_CMultiStatementExpression**(*obj*)

**handle_CVectorConvert**(*obj*)

**handle_CVEXCCallExpression**(*obj*)

**handle_CDirtyExpression**(*obj*)

**class** angr.analyses.decompiler.structured_codegen.c.**MakeTypecastsImplicit**

Bases: *CStructuredCodeWalker*

**classmethod collapse**(*dst_ty*, *child*)

**Return type**
*CExpression*

**Parameters**

- **dst_ty** (SimType)
- **child** (CExpression)

**handle_CAssignment**(*obj*)

**handle_CFunctionCall**(*obj*)

**Parameters**
**obj** (CFunctionCall)

**handle_CReturn**(*obj*)

**Parameters**
**obj** (CReturn)

**handle_CBinaryOp**(*obj*)

**Parameters**
**obj** (CBinaryOp)

**handle_CTypeCast**(*obj*)

**Parameters**
**obj** (CTypeCast)

**class** angr.analyses.decompiler.structured_codegen.c.**FieldReferenceCleanup**

Bases: *CStructuredCodeWalker*

**handle_CTypeCast**(*obj*)

**class** angr.analyses.decompiler.structured_codegen.c.**PointerArithmeticFixer**

Bases: *CStructuredCodeWalker*

Before calling this fixer class, pointer arithmetics are purely integer-based and ignoring the pointer type.

For example, in the following case:

struct A* a_ptr; // assume struct A is 24 bytes in size a_ptr = a_ptr + 24;

It means adding 24 to the address of a_ptr, without considering the size of struct A. This fixer class will make pointer arithmetics aware of the pointer type. In this case, the fixer class will convert the code to a_ptr = a_ptr + 1.

**handle_CAssignment**(*obj*)

**Parameters**
**obj** (CAssignment)

**handle_CBinaryOp**(*obj*)

**Parameters**
**obj** (CBinaryOp)

### angr.analyses.decompiler.structured_codegen.c_serialize

Protobuf serialization helpers for the C AST defined in `c`.

The AST is serialized as a flat indexed table of `CConstructNode` cmessages: every `CConstruct` instance is assigned a non-zero `uint32` node_id at serialize time, and child CConstructs are referenced by id. This avoids unbounded recursion in protobuf encoding and lets `PositionMapping`, `cexterns`, and `map_addr_to_label` reference into the AST without duplicating subtrees.

**class** angr.analyses.decompiler.structured_codegen.c_serialize.**SerializeContext**

Bases: `object`

Tracks which nodes have been serialized while walking the C AST.

**__init__**()

**Return type**
None

**nodes:** `list[CConstructNode]`

**type_json_memo**(*t*)

The memo a type is encoded with; a flavor may pre-seed it so some named types are written by name.

**Return type**
dict | None

**Parameters**
**t** (SimType)

**intern_type**(*t*)

Intern a SimType's JSON encoding and return its ref (index+1 into the type pool); 0 for None.

**Return type**
int

**Parameters**
**t** (*SimType | None*)

**property type_pool: list[str]**

**intern_tags**(*tags*)

Intern a sanitized tags dict and return its ref (index+1 into the tag pool); 0 for no tags.

**Return type**
int

**Parameters**
**tags** (*dict | None*)

**property tag_pool: list[CConstructTags]**

**intern_simvar**(*v*)

Intern a SimVariable's polymorphic payload and return its ref (index+1 into the pool); 0 for None.

**Return type**
int

**Parameters**
**v** (*SimVariable | None*)

**property simvar_pool: list[bytes]**

**add_cfuncall_config**(*node_id*, *show_demangled_name*, *show_disambiguated_name*)

**Return type**
None

**Parameters**

- **node_id** (*int*)
- **show_demangled_name** (*bool*)
- **show_disambiguated_name** (*bool*)

**property node_config: list[NodeConfigEntry]**

**node_id**(*node*)

The id a node is stored under. C nodes carry their own (CConstruct.idx).

**Return type**
int

**write_base_fields**(*node*, *pb*)

Write the family-dependent base fields of a node.

**Return type**
None

**serialize**(*node*)

Serialize node (recursively) and return its node_id. 0 indicates absent.

**Return type**
int

**Parameters**
**node** (*CConstruct | None*)

**class** angr.analyses.decompiler.structured_codegen.c_serialize.**ParseContext**

Bases: object

Tracks and resolves node.idx to the corresponding C AST.

**__init__**(*nodes_msg*, *project=None*, *kb=None*, *type_pool=()*, *tag_pool=()*, *simvar_pool=()*, *node_config=None*)

**Return type**
None

**project**

**kb**

**cfuncall_config**(*node_id*)

(show_demangled_name, show_disambiguated_name) for a CFunctionCall node; defaults to (True, True).

**Return type**
tuple[bool, bool]

**Parameters**
**node_id** (*int*)

**resolve_function**(*addr*)

**Return type**
*Function* | *FunctionRef* | None

**Parameters**
**addr** (*int*)

**resolve_type**(*ref*)

Resolve a type-pool ref (index+1; 0 means absent) into a fresh SimType instance, arch-bound so it can report its size when re-rendered.

**Return type**
*SimType* | None

**Parameters**
**ref** (*int*)

**resolve_simvar**(*ref*)

Resolve a simvar-pool ref (index+1; 0 means absent) into a fresh SimVariable instance.

**Return type**
*SimVariable* | None

**Parameters**
**ref** (*int*)

**resolve_tags**(*ref*)

Resolve a tag-pool ref (index+1; 0 means no tags) into a fresh tags dict.

**Return type**
dict

**Parameters**
**ref** (*int*)

**parser_for**(*kind*)

**Parameters**
**kind** (*int*)

**apply_base_state**(*obj*, *pb*)

Restore the family-dependent base state of a parsed node.

**Return type**
None

**resolve**(*node_id*)

**Parameters**
**node_id** (*int*)

**set_codegen**(*codegen*)

**Return type**
None

angr.analyses.decompiler.structured_codegen.c_serialize.**serialize_subtree**(*root*)

Serialize an AST subtree as a Codegen envelope carrying only the indexed table + root_id. For testing and any caller that wants to round-trip a CConstruct without a full codegen object.

**Return type**
bytes

**Parameters**
**root** (CConstruct)

angr.analyses.decompiler.structured_codegen.c_serialize.**parse_subtree**(*data*, *project=None*, *kb=None*)

**Return type**
*CConstruct* | None

**Parameters**
**data** (bytes)

angr.analyses.decompiler.structured_codegen.c_serialize.**serialize_codegen**(*codegen*)

Build a Codegen cmessage from a live CStructuredCodeGenerator instance.

**Return type**
Codegen

angr.analyses.decompiler.structured_codegen.c_serialize.**parse_codegen**(*msg*, ***, *project=None*, *kb=None*, *func=None*)

Create a CStructuredCodeGenerator from a Codegen cmessage. Bypasses __init__ (which runs the full decompilation pipeline) and populates the attributes directly. The parsed instance is suitable for display, navigation, and cache-validity checks; re-rendering and re-running analyses require `project` / `func` / `kb` to be reattached. Decompilation variables are read from `kb.dec_variables`.

angr.analyses.decompiler.structured_codegen.c_serialize.**register_all**()

Registers serializer/parser pairs for every concrete CConstruct subclass. Called from c.py at import time.

**Return type**
None

### angr.analyses.decompiler.structured_codegen.dummy

class angr.analyses.decompiler.structured_codegen.dummy.**DummyStructuredCodeGenerator**

Bases: *BaseStructuredCodeGenerator*, *Serializable*

A dummy structured code generator that only stores user-specified information.

**__init__**(*flavor*, *expr_comments=None*, *stmt_comments=None*, *configuration=None*, *const_formats=None*)

**Parameters**
**flavor** (*str*)

### angr.analyses.decompiler.structured_codegen.dwarf_import

class angr.analyses.decompiler.structured_codegen.dwarf_import.**ImportedLine**

Bases: object

**__init__**(*addr*)

class angr.analyses.decompiler.structured_codegen.dwarf_import.**ImportSourceCode**

Bases: *BaseStructuredCodeGenerator*, *Analysis*

**__init__**(*function*, *flavor='source'*, *source_root=None*, *encoding='utf-8'*)

**regenerate_text**()

### angr.analyses.decompiler.structured_codegen.go

Go-flavored structured code generator. A fork of the C backend (c.py) that renders Go syntax.

type angr.analyses.decompiler.structured_codegen.go.**RenderResult** = tuple[str, *PositionMapping*, *PositionMapping*, *InstructionMapping*, dict[Any, set[Any]]]

angr.analyses.decompiler.structured_codegen.go.**qualifies_for_simple_cast**(*ty1*, *ty2*)

angr.analyses.decompiler.structured_codegen.go.**qualifies_for_width_cast**(*ty*)

angr.analyses.decompiler.structured_codegen.go.**qualifies_for_implicit_cast**(*ty1*, *ty2*)

angr.analyses.decompiler.structured_codegen.go.**extract_terms**(*expr*)

**Return type**
tuple[int, list[tuple[int, *GoExpression*]]]

**Parameters**
**expr** (GoExpression)

angr.analyses.decompiler.structured_codegen.go.**is_machine_word_size_type**(*type_*, *arch*)

**Return type**
bool

**Parameters**

- **type_** (SimType)
- **arch** (*archinfo.Arch*)

angr.analyses.decompiler.structured_codegen.go.**guess_value_type**(*value*, *project*)

**Return type**
*SimType* | None

**Parameters**

- **value** (*int*)
- **project** (*angr.Project*)

angr.analyses.decompiler.structured_codegen.go.**type_equals**(*t0*, *t1*)

**Return type**
bool

**Parameters**

- **t0** (SimType)
- **t1** (SimType)

angr.analyses.decompiler.structured_codegen.go.**type_layout_key**(*ty*, *_seen=frozenset({})*)

A structural sort key for a type, derived purely from its memory layout (sizes, field offsets, and the layouts of field/element/pointee types) and not from any user-renamable struct or field name. This lets the code generator order type definitions stably without their order changing when the user renames a struct or a field. Cycles through recursive struct/pointer references are broken with a marker.

**Return type**
str

**Parameters**
**_seen** (*frozenset*)

angr.analyses.decompiler.structured_codegen.go.**cextern_sort_key**(*cextern*)

A stable sort key for extern variables, based on the variable's address. Unlike the variable name, the address does not change when the user renames the variable, so the ordering of extern definitions stays put across renames.

**Return type**
tuple

angr.analyses.decompiler.structured_codegen.go.**go_type_str**(*ty*, *memo=None*)

Spell a SimType the Go way. Only C-flavored SimTypes reach here until Go-specific SimTypes exist; they are mapped onto the closest Go builtin by size and signedness.

**Return type**
str

**Parameters**

- **ty** (SimType | *None*)
- **memo** (*set[int]* | *None*)

angr.analyses.decompiler.structured_codegen.go.**type_to_go_repr_chunks**(*ty*, *name=None*, *name_type=None*, *full=False*, *indent_str=''*, *indent_delta=4*, *memo=None*)

Helper generator function to turn a SimType into generated tuples of (Go-string, AST node).

Go declarations put the name first (`name T`); a full struct definition renders as `type Name struct {...}`.

**Parameters**

- **ty** (SimType)
- **indent_delta** (*int*)
- **memo** (*set[int] | None*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoConstruct**

Bases: object

Represents a program construct in C. Acts as the base class for all other representation constructions.

**__init__**(*codegen*, *tags=None*)

**Parameters**
**codegen** (GoStructuredCodeGenerator)

**tags**

**codegen:** *GoStructuredCodeGenerator*

**ident:** str

**idx:** int

**c_repr**(*initial_pos=0*, *indent=0*, *pos_to_node=None*, *pos_to_addr=None*, *addr_to_pos=None*)

Creates the C representation of the code and displays it by constructing a large string. This function is called by each program function that needs to be decompiled. The map_pos_to_node and map_pos_to_addr act as position maps for the location of each variable and statement to be tracked for later GUI operations. The map_pos_to_addr also contains expressions that are nested inside of statements.

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**static indent_str**(*indent=0*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoFunction**

Bases: *GoConstruct*, *FunctionNode*

Represents a function in C.

**__init__**(*addr*, *name*, *functy*, *arg_list*, *statements*, *variables_in_use*, *variable_manager*, *demangled_name=None*, *show_demangled_name=True*, *omit_header=False*, ***kwargs*)

**Parameters**

- **addr** (*int*)
- **name** (*str*)
- **functy** (SimTypeFunction)
- **arg_list** (*list[GoVariable]*)

**addr**

**name**

**functy**

**arg_list**

**statements**

**variables_in_use**

**variable_manager:** *VariableManagerInternal*

**demangled_name**

**unified_local_vars:** dict[*SimVariable*, set[tuple[*GoVariable*, *SimType*]]]

**show_demangled_name**

**omit_header**

**extra_decls:** list[tuple[str, *SimType*]]

**short_declared:** set

**refresh**()

**get_unified_local_vars**()

**Return type**
dict[*SimVariable*, set[tuple[*GoVariable*, *SimType*]]]

**variable_list_repr_chunks**(*indent=0*)

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**headerless_c_repr_chunks**(*indent=0*)

**full_c_repr_chunks**(*indent=0*, *asexpr=False*)

**static sort_local_vars**(*local_vars*)

**Return type**
list[*SimVariable*]

**Parameters**
**local_vars** (*Iterable*[SimVariable])

**class** angr.analyses.decompiler.structured_codegen.go.**GoStatement**

Bases: *GoConstruct*

Represents a statement in C.

**__init__**(*tags=None*, ***, *codegen*)

**Parameters**
**codegen** (GoStructuredCodeGenerator)

**codegen:** *GoStructuredCodeGenerator*

**ident:** str

**idx:** *int*

**tags**

**class** angr.analyses.decompiler.structured_codegen.go.**GoExpression**

Bases: *GoConstruct*, *ExpressionNode*

Base class for C expressions.

**__init__**(*collapsed=False*, *tags=None*, ***, *codegen*)

**Parameters**
**codegen** (GoStructuredCodeGenerator)

**collapsed**

**property type:** *SimType* | None

**set_type**(*v*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoStatements**

Bases: *GoStatement*

Represents a sequence of statements in C.

**__init__**(*statements*, *addr=None*, ***kwargs*)

**Parameters**
**statements** (*Sequence*[GoStatement])

**statements**

**addr**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoAILBlock**

Bases: *GoStatement*

Represents a block of AIL statements.

**__init__**(*block*, ***kwargs*)

**Parameters**
**block** (*Block*)

**block**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoLoop**

Bases: *GoStatement*

Represents a loop in C.

**class** angr.analyses.decompiler.structured_codegen.go.**GoWhileLoop**

Bases: *GoLoop*

Represents a while loop in C.

**__init__**(*condition*, *body*, ***kwargs*)

**Parameters**

- **condition** (GoExpression)
- **body** (GoStatements | *None*)

**condition**

**body**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.go.**GoDoWhileLoop**

Bases: *GoLoop*

Represents a do-while loop in C.

**__init__**(*condition*, *body*, ***kwargs*)

**Parameters**

- **condition** (GoExpression)
- **body** (GoStatements | *None*)

**condition**

**body**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.go.**GoForLoop**

Bases: *GoStatement*

Represents a for-loop in C.

**__init__**(*initializer*, *condition*, *iterator*, *body*, ***kwargs*)

**Parameters**

- **condition** (GoExpression | *None*)
- **body** (GoStatements | *None*)

**initializer**

**condition**

**iterator**

**body**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.go.**GoRangeLoop**

Bases: *GoStatement*

`for i, v = range coll { ... }`; `index`/`value` may be None (rendered as `_`).

__init__(*index*, *value*, *collection*, *body*, ***kwargs*)

**Parameters**

- **collection** (GoExpression)
- **body** (GoStatements | *None*)

**index**

**value**

**collection**

**body**

**declares**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.go.**GoIfElse**

Bases: *GoStatement*

Represents an if-else construct in C.

__init__(*condition_and_nodes*, *else_node=None*, *simplify_else_scope=False*, *cstyle_ifs=True*, ***kwargs*)

**Parameters**

**condition_and_nodes** (*list[tuple[GoExpression, GoStatement | None]]*)

**condition_and_nodes**

**else_node**

**simplify_else_scope**

**cstyle_ifs**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.go.**GoIfBreak**

Bases: *GoStatement*

Represents an if-break statement in C.

__init__(*condition*, *cstyle_ifs=True*, ***kwargs*)

**Parameters**

**condition** (GoExpression)

**condition**

**cstyle_ifs**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.go.**GoBreak**

Bases: *GoStatement*

Represents a break statement in C.

__init__(***kwargs*)

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoContinue**

Bases: *GoStatement*

Represents a continue statement in C.

**__init__**(***kwargs*)

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoSwitchCase**

Bases: *GoStatement*

Represents a switch-case statement in C.

**__init__**(*switch*, *cases*, *default*, ***kwargs*)

**Parameters**

- **switch** (GoExpression)
- **cases** (*Sequence[tuple[int | tuple[int, ...], GoStatements]]*)
- **default** (GoStatements | *None*)

**switch**

**cases**

**default**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoIncompleteSwitchCase**

Bases: *GoStatement*

Represents an incomplete switch-case construct; this only appear in the decompilation output when switch-case structuring fails (for whatever reason).

**__init__**(*head*, *cases*, ***kwargs*)

**head**

**cases:** list[tuple[int, *GoStatements*]]

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoAssignment**

Bases: *GoStatement*

a = b

**__init__**(*lhs*, *rhs*, ***kwargs*)

**Parameters**

**rhs** (GoExpression)

**lhs**

**rhs**

**declares**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoMethodCall**

Bases: *GoExpression*

`recv.Method(args)` through an interface's method table.

**__init__**(*receiver*, *method*, *args*, *signature=None*, ***kwargs*)

**Parameters**

- **method** (*str*)
- **args** (*Sequence[GoExpression]*)

**receiver**

**method**

**args**

**signature**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoMultiAssignment**

Bases: *GoStatement*

`a, b = f()`

**__init__**(*lhs*, *rhs*, ***kwargs*)

**lhs**

**rhs**

**declares**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoSelectCase**

Bases: `object`

One `select` case: a receive (`v, ok := <-ch`), a send (`ch <- x`) or the default.

**__init__**(*kind*, *channel=None*, *value=None*, *ok=None*)

**Parameters**

**kind** (*str*)

**kind**

**channel**

**value**

**ok**

c_repr_chunks()

class angr.analyses.decompiler.structured_codegen.go.GoSelect

Bases: GoStatement

select { case ...:  ...  }

__init__(*cases*, ***kwargs*)

cases

c_repr_chunks(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.go.GoTypeSwitch

Bases: GoStatement

switch x := v.(type) { case T: ... default:  ...  }

__init__(*value*, *bound_name*, *cases*, *default*, ***kwargs*)

**Parameters**
**bound_name** (*str | None*)

value

bound_name

cases

default

c_repr_chunks(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.go.GoExpressionStatement

Bases: GoStatement

Wraps a GoExpression so it can be used as a standalone statement.

expr;

__init__(*expr*, *returning=True*, ***kwargs*)

**Parameters**
- **expr** (GoExpression)
- **returning** (*bool | None*)

expr

returning

c_repr_chunks(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.go.GoFunctionCall

Bases: GoExpression, FunctionCallNode

func(arg0, arg1)

**Variables**
**callee_func** (Function) – The function getting called.

__init__(*callee_target*, *callee_func*, *args*, *show_demangled_name=True*, *show_disambiguated_name=True*, *tags=None*, *, *codegen*, **kwargs*)

**Parameters**
**show_disambiguated_name** (*bool*)

**callee_target**

**args**

**show_demangled_name**

**show_disambiguated_name**

**site_returnty: *SimType* | None**

**property callee_func: *Function* | None**

**property callee_func_addr: int | None**
The callee's address, without loading the callee.

**property prettify_thiscall: bool**

**property prototype: *SimTypeFunction* | None**

**property prototype_returnty: *SimType***
Returns returnty and avoids creating the SimTypeFunction instance if the function prototype is not available. Instead of self.prototype.returnty, you should use self.prototype_returnty for better performance.

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoReturn**
Bases: *GoStatement*

return with zero, one or several result expressions.

__init__(*retval*, **kwargs*)

**Parameters**
**retval** (*GoExpression | None*)

**retvals**

**property retval**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoGoto**
Bases: *GoStatement*

__init__(*target*, *target_idx*, **kwargs*)

**Parameters**
- **target** (*GoExpression | int*)
- **target_idx** (*int*)

**target: int | *GoExpression***

**target_idx**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoUnsupportedStatement**

Bases: *GoStatement*

A wrapper for unsupported AIL statement.

**__init__**(*stmt*, ***kwargs*)

**stmt**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoDirtyStatement**

Bases: *GoExpression*

**__init__**(*dirty*, ***kwargs*)

**Parameters**
**dirty** (GoDirtyExpression)

**dirty**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoLabel**

Bases: *GoStatement*, *LabelNode*

Represents a label in C code.

**__init__**(*name*, ***kwargs*)

**Parameters**
**name** (*str*)

**name**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoStructField**

Bases: *GoExpression*, *StructFieldNode*

**__init__**(*struct_type*, *offset*, *field*, ***kwargs*)

**Parameters**

- **struct_type** (SimStruct)
- **offset** (*int*)
- **field** (*str*)

**struct_type**

**offset**

**field**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoFakeVariable**

Bases: *GoExpression*

An uninterpreted name to display in the decompilation output. Pretty much always represents an error?

**__init__**(*name*, *ty*, ***kwargs*)

**Parameters**

- **name** (*str*)
- **ty** (SimType)

**name**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoVariable**

Bases: *GoExpression*, *VariableNode*

GoVariable represents access to a variable with the specified type (*variable_type*).

*variable* must be a SimVariable.

**__init__**(*variable*, *unified_variable=None*, *variable_type=None*, *vvar_id=None*, ***kwargs*)

**Parameters**

**variable** (SimVariable)

**variable:** *SimVariable*

**unified_variable:** *SimVariable* | None

**variable_type:** *SimType* | None

**vvar_id**

**property type**

**property name**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoIndexedVariable**

Bases: *GoExpression*, *IndexedVariableNode*

Represent a variable (an array) that is indexed.

**__init__**(*variable*, *index*, *variable_type=None*, ***kwargs*)

**Parameters**

- **variable** (GoExpression)
- **index** (GoExpression)

**index:** *GoExpression*

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**collapsed**

**class** angr.analyses.decompiler.structured_codegen.go.**GoVariableField**

Bases: *GoExpression*, *VariableFieldNode*

Represent a field of a variable.

**__init__**(*variable*, *field*, *var_is_ptr=False*, ***kwargs*)

**Parameters**

- **variable** (GoExpression)
- **field** (GoStructField)
- **var_is_ptr** (*bool*)

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**collapsed**

**class** angr.analyses.decompiler.structured_codegen.go.**GoUnaryOp**

Bases: *GoExpression*, *UnaryOpNode*

Unary operations.

**__init__**(*op*, *operand*, ***kwargs*)

**Parameters**
**operand** (GoExpression)

**op**

**operand**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoBinaryOp**

Bases: *GoExpression*, *BinaryOpNode*

Binary operations.

**__init__**(*op*, *lhs*, *rhs*, ***kwargs*)

**op**

**lhs**

**rhs**

**signed:** bool | None

**common_type**

**static compute_common_type**(*op*, *lhs_ty*, *rhs_ty*)

**Return type**
*SimType*

**Parameters**

- **op** (*str*)
- **lhs_ty** (SimType)
- **rhs_ty** (SimType)

**property type**

**property op_precedence**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoTypeCast**

Bases: *GoExpression*

**__init__**(*src_type*, *dst_type*, *expr*, ***kwargs*)

**Parameters**

- **src_type** (SimType | *None*)
- **dst_type** (SimType)
- **expr** (GoExpression)

**src_type**

**dst_type**

**expr**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoConstant**

Bases: *GoExpression*, *ConstantNode*

**__init__**(*value*, *type_*, *reference_values=None*, ***kwargs*)

**Parameters**
**type_** (SimType)

**value: int | float | str**

**string_data: str | None**

**property reference_values: dict | None**

**property raw_reference_values: dict | None**

The reference values, without loading the functions a parsed constant refers to.

**property fmt**

**property fmt_hex**

property fmt_neg

property fmt_char

Setter accepts
bool

property fmt_float

Setter accepts
bool

property fmt_double

Setter accepts
bool

property type

static str_to_c_str(*_str*, *prefix=''*, *maxlen=None*)

Return type
str

Parameters

- **prefix** (*str*)
- **maxlen** (*int | None*)

c_repr_chunks(*indent=0*, *asexpr=False*)

fmt_int(*value*)

Format an integer using the format setup of the current node.

Parameters
**value** (int) – The integer value to format.

Return type
str

Returns
The formatted string.

class angr.analyses.decompiler.structured_codegen.go.GoRegister

Bases: *GoExpression*

__init__(*reg*, ***kwargs*)

reg

property type

c_repr_chunks(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.go.GoITE

Bases: *GoExpression*

__init__(*cond*, *iftrue*, *iffalse*, ***kwargs*)

cond

**iftrue**

**iffalse**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.go.**GoMultiStatementExpression**

Bases: *GoExpression*

(stmt0, stmt1, stmt2, expr)

**__init__**(*stmts*, *expr*, ***kwargs*)

**Parameters**

- **stmts** (GoStatements)
- **expr** (GoExpression)

**stmts**

**expr**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.go.**GoVEXCCallExpression**

Bases: *GoExpression*

ccall_name(arg0, arg1, ...)

**__init__**(*callee*, *operands*, ***kwargs*)

**Parameters**

- **callee** (*str*)
- **operands** (*list[GoExpression]*)

**callee**

**operands**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.go.**GoDirtyExpression**

Bases: *GoExpression*

Ideally all dirty expressions should be handled and converted to proper conversions during conversion from VEX to AIL. Eventually this class should not be used at all.

**__init__**(*dirty*, ***kwargs*)

**dirty**

**property type**

**intrinsic_name**()

Return the dirty callee if it is a clean C identifier, else None.

**Return type**
str | None

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoStringLiteral**

Bases: *GoExpression*

A Go string constant (pointer, length) known at decompilation time.

**__init__**(*data*, *tags=None*, ***kwargs*)

**Parameters**
**data** (*str*)

**data**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoStructLiteral**

Bases: *GoExpression*

A struct-shaped value assembled from its fields: a composite literal `T{a: x, b: y}`, or `nil`/`""` when every field is zero.

**__init__**(*name*, *fields*, *field_names*, *tags=None*, ***kwargs*)

**Parameters**
**name** (*str*)

**name**

**fields**

**field_names**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoBoxedValue**

Bases: *GoExpression*

A value converted to an interface: `x` when its static type already is the boxed type, `T(x)` otherwise.

**__init__**(*expr*, *iface_name*, *concrete*, *tags=None*, ***kwargs*)

**Parameters**

- **iface_name** (*str*)
- **concrete** (*str | None*)

**expr**

**iface_name**

**concrete**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoTypeAssertion**

Bases: *GoExpression*

`x.(T)`, or the interface conversion `T(x)` when `conversion` is set.

**__init__**(*expr*, *type_name*, *tags=None*, *conversion=False*, ***kwargs*)

**Parameters**

- **type_name** (*str*)
- **conversion** (*bool*)

**expr**

**type_name**

**conversion**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoSliceLiteral**

Bases: *GoExpression*

`[]T{a, b, c}`

**__init__**(*elem_type*, *elems*, *tags=None*, ***kwargs*)

**Parameters**

**elem_type** (*str*)

**elem_type**

**elems**

**property type**

**elem_chunks**()

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.go.**GoClosingObject**

Bases: *ClosingObjectNode*

A class to represent all objects that can be closed by it's correspodning character. Examples: (), {}, []

**__init__**(*opening_symbol*)

**opening_symbol**

**class** angr.analyses.decompiler.structured_codegen.go.**GoArrayTypeLength**

Bases: `object`

A class to represent the type information of fixed-size array lengths. Examples: In "char foo[20]", this would be the "[20]".

__init__(*text*)

**text**

class angr.analyses.decompiler.structured_codegen.go.**GoStructFieldNameDef**

Bases: object

A class to represent the name of a defined field in a struct. Needed because it's not a GoVariable or a GoStructField (because GoStructField is the access of a GoStructField). Example: In "struct foo { int bar; }, this would be "bar".

__init__(*name*)

**name**

class angr.analyses.decompiler.structured_codegen.go.**GoStructuredCodeGenerator**

Bases: *BaseStructuredCodeGenerator*, *Analysis*, *Serializable*

__init__(*func*, *sequence*, *indent=0*, *cfg=None*, *func_args=None*, *binop_depth_cutoff=16*, *show_casts=True*, *braces_on_own_lines=False*, *use_compound_assignments=True*, *show_local_types=True*, *comment_gotos=False*, *cstyle_null_cmp=True*, *flavor=None*, *stmt_comments=None*, *expr_comments=None*, *show_externs=True*, *externs=None*, *const_formats=None*, *show_demangled_name=True*, *show_disambiguated_name=True*, *ail_graph=None*, *simplify_else_scope=True*, *cstyle_ifs=True*, *omit_func_header=False*, *display_block_addrs=False*, *display_vvar_ids=False*, *min_data_addr=4194304*, *notes=None*, *display_notes=True*, *max_str_len=None*, *prettify_thiscall=False*, *cstyle_void_param=True*, *indent_size=4*, *variable_map=None*, *stl_accessor_calls=False*)

**Parameters**

- **func_args** (*list[SimVariable] | None*)
- **binop_depth_cutoff** (*int*)
- **min_data_addr** (*int*)
- **display_notes** (*bool*)
- **max_str_len** (*int | None*)
- **prettify_thiscall** (*bool*)
- **cstyle_void_param** (*bool*)
- **indent_size** (*int*)
- **variable_map** (*VariableMap | None*)
- **stl_accessor_calls** (*bool*)

**ailexpr2cnode:** dict[tuple[*Expression* | *Statement*, bool], *GoExpression*] | None

**cnode2ailexpr:** dict[*GoExpression*, *Expression* | *Statement*] | None

**map_addr_to_label:** dict[tuple[int, int | None], *GoLabel*]

**cfunc:** *GoFunction* | None

**cexterns:** set[*GoVariable*] | None

**reapply_options**(*options*)

**cleanup**()

Remove existing rendering results.

**regenerate_text**()

Re-render text and re-generate all sorts of mapping information.

**Return type**
None

**render_text**(*cfunc*)

**Return type**

**Parameters**
**cfunc** (GoFunction)

**render_notes**()

Render decompilation notes.

**Return type**
str

**Returns**
A string containing all notes.

**reload_variable_types**()

**Return type**
None

**default_simtype_from_bits**(*n*, *signed=True*)

**Return type**
*SimType*

**Parameters**

- **n** (*int*)
- **signed** (*bool*)

**variables_unify**(*v1*, *v2*)

**Return type**
bool

**Parameters**

- **v1** (VirtualVariable)
- **v2** (VirtualVariable)

**property map_ast_to_pos:** dict[Any, set[*PositionMappingElement*]] | None

**resolve_callee**(*addr*)

The function at addr for a parsed call, the same object for every call to it.

**Return type**
*Function* | None

**Parameters**
**addr** (*int*)

class angr.analyses.decompiler.structured_codegen.go.**GoStructuredCodeWalker**

Bases: object

**handle**(*obj*)

**handle_default**(*obj*)

**handle_GoFunction**(*obj*)

**handle_GoStatements**(*obj*)

**handle_GoWhileLoop**(*obj*)

**handle_GoDoWhileLoop**(*obj*)

**handle_GoRangeLoop**(*obj*)

**handle_GoMethodCall**(*obj*)

**handle_GoMultiAssignment**(*obj*)

**handle_GoStructLiteral**(*obj*)

**handle_GoBoxedValue**(*obj*)

**handle_GoTypeSwitch**(*obj*)

**handle_GoSelect**(*obj*)

**handle_GoTypeAssertion**(*obj*)

**handle_GoSliceLiteral**(*obj*)

**handle_GoForLoop**(*obj*)

**handle_GoIfElse**(*obj*)

**handle_GoIfBreak**(*obj*)

**handle_GoSwitchCase**(*obj*)

**handle_GoAssignment**(*obj*)

**handle_GoExpressionStatement**(*obj*)

**handle_GoFunctionCall**(*obj*)

**handle_GoReturn**(*obj*)

**handle_GoGoto**(*obj*)

**handle_GoIndexedVariable**(*obj*)

**handle_GoVariableField**(*obj*)

**handle_GoUnaryOp**(*obj*)

**handle_GoBinaryOp**(*obj*)

**handle_GoTypeCast**(*obj*)

**handle_GoITE**(*obj*)

**class** angr.analyses.decompiler.structured_codegen.go.**RangeLoopRecovery**

Bases: *GoStructuredCodeWalker*

Turn a counting loop over a slice or string into `for i, x = range s`: the index starts at zero (in the loop initializer or just before the loop), the condition is `i < len(s)` (the length possibly hoisted into a variable or the initializer) and the index advances by one per iteration. The range value is bound from `x = s.ptr[i]` at the top of the body, or from a pointer that starts at `s.ptr` and advances by one element at the end of the body.

**__init__**(*codegen*)

**handle_GoFunction**(*obj*)

**handle_GoStatements**(*obj*)

**class** angr.analyses.decompiler.structured_codegen.go.**TupleDestructuring**

Bases: *GoStructuredCodeWalker*

`v = f()` followed by `v.~r0` / `v.~r1` accesses of a multi-result value becomes `a, err = f()` with one variable per result, when the value is only ever read through its fields.

**__init__**(*codegen*, *cfunc*)

**Parameters**
**cfunc** (GoFunction)

**collect**(*node*, *chain=()*)

`chain` is the ancestry as (node, attribute, index-or-key) triples, innermost last.

**Parameters**
**chain** (*tuple*)

**run**()

**handle_GoAssignment**(*obj*)

**handle_GoVariableField**(*obj*)

**handle_GoVariable**(*obj*)

**handle_GoUnaryOp**(*obj*)

**handle_GoBinaryOp**(*obj*)

**class** angr.analyses.decompiler.structured_codegen.go.**PrintFolding**

Bases: *GoStructuredCodeWalker*

Fold the `printlock; print<T>(a); printsp; ...; printnl; printunlock` sequence the compiler emits for the `print`/`println` builtins back into one call.

**__init__**(*codegen*)

**handle_GoStatements**(*obj*)

**class** angr.analyses.decompiler.structured_codegen.go.**InterfaceMethodCalls**

Bases: *GoStructuredCodeWalker*

`x.tab.fun[i](x.data, args...)` becomes `x.Method(args...)` using the interface's method set.

**__init__**(*codegen*)

**handle_GoFunction**(*obj*)

**handle_GoFunctionCall**(*obj*)

**class** angr.analyses.decompiler.structured_codegen.go.**TypeAssertionRecovery**

Bases: *GoStructuredCodeWalker*

`if v.tab == &type:T` guarding reads of `v.data` becomes `x, ok := v.(T)` followed by `if ok`; the same check guarding only a `runtime.panicdottype*` call is the panicking form `v.(T)`.

**PANIC_NAMES = frozenset({'runtime.panicdottypeE', 'runtime.panicdottypeI', 'runtime.panicnildottype'})**

**__init__**(*codegen*, *cfunc*)

**Parameters**
**cfunc** (GoFunction)

**run**()

**handle_GoStatements**(*obj*)

**class** angr.analyses.decompiler.structured_codegen.go.**InterfaceAssertionRecovery**

Bases: *TypeAssertionRecovery*

Assertions and conversions to interface types, which go through `runtime.typeAssert`. Runs late: the holder needs its interface type and the spill copies around the call must be gone.

**changed = False**

**handle_GoStatements**(*obj*)

**class** angr.analyses.decompiler.structured_codegen.go.**ITEHoisting**

Bases: object

`x = c ? a : b` renders as an immediately invoked closure in Go. Inside a statement list the value is hoisted into a temporary assigned by an `if/else` placed before the statement; ITEs in loop headers stay as they are.

**__init__**(*codegen*, *cfunc*)

**Parameters**
**cfunc** (GoFunction)

**run**()

**class** angr.analyses.decompiler.structured_codegen.go.**NamedFieldRetyping**

Bases: object

Field accesses built on register copies carry the copy's inferred struct; once copy cleanup has folded them onto an expression whose type is a named Go struct, name the fields after that struct. Variables defined by such a read take its type, so the fix propagates through chains of copies and indexing.

**MAX_ROUNDS = 4**

**__init__**(*codegen*, *cfunc*)

**Parameters**
**cfunc** (GoFunction)

**run**()

class angr.analyses.decompiler.structured_codegen.go.**StringSwitchRecovery**

Bases: *GoStructuredCodeWalker*

An if/else-if chain whose conditions all compare one string with literals is a `switch` on it.

**__init__**(*codegen*)

**handle_GoIfElse**(*obj*)

**handle_GoBinaryOp**(*obj*)

class angr.analyses.decompiler.structured_codegen.go.**TypeSwitchRecovery**

Bases: *GoStructuredCodeWalker*

An if/else-if chain comparing one interface value's type word against type descriptors becomes `switch x := v.(type)`; a trailing `runtime.interfaceSwitch` dispatch adds the interface cases.

**__init__**(*codegen*, *cfunc*)

**Parameters**
**cfunc** (GoFunction)

**run**()

**handle_GoStatements**(*obj*)

**handle_GoSwitchCase**(*obj*)

class angr.analyses.decompiler.structured_codegen.go.**MapRangeRecovery**

Bases: *GoStructuredCodeWalker*

`runtime.mapiterinit(T, m, &it)` followed by a loop on `it.key != nil` that ends with `runtime.mapiternext(&it)` becomes `for k, v = range m`; reads through the iterator's key and element pointers become `k` and `v`.

**__init__**(*codegen*, *cfunc*)

**Parameters**
**cfunc** (GoFunction)

**run**()

**handle_GoStatements**(*obj*)

class angr.analyses.decompiler.structured_codegen.go.**ChannelRangeRecovery**

Bases: *GoStructuredCodeWalker*

`for { S; v, ok = <-ch; if !ok { break }; R }` becomes `S; for v = range ch { R; S }`: the statements ahead of the receive also run on the final, failed receive, so they move before the loop and to the end of the body.

**__init__**(*codegen*, *cfunc*)

**Parameters**
**cfunc** (GoFunction)

**run**()

**handle_GoStatements**(*obj*)

**class** angr.analyses.decompiler.structured_codegen.go.**SingleTripLoops**

Bases: *GoStructuredCodeWalker*

`for i = 0; i <= 0; i = 1 { body }` runs its body exactly once (a range over a one-element array, e.g. an inlined `append` of one value): emit the body (and the iterator) without the loop. The flag variable must be written only by the initializer and unconditional constant stores, and read only by the condition.

**__init__**(*codegen*, *cfunc*)

**Parameters**
**cfunc** (GoFunction)

**run**()

**handle_GoStatements**(*obj*)

**class** angr.analyses.decompiler.structured_codegen.go.**UnreachableAfterReturn**

Bases: *GoStructuredCodeWalker*

Statements after a `return` in the same block that no goto can reach are dropped.

**handle_GoStatements**(*obj*)

**class** angr.analyses.decompiler.structured_codegen.go.**CopyCleanup**

Bases: object

Remove the register shuffling that phi elimination and spilling leave in structured code:

- a value spilled before a loop and reloaded inside it (`x = y … y = x`) never changes, so the spill and the reloads go and `x` reads as `y`;
- `x = y` whose every read follows in the same block, with `y` unchanged in between, is folded into the reads;
- single-assignment locals nobody reads are dropped.

A loop whose iterator statement went away takes the body's final update of a condition variable as its iterator.

**MAX_ROUNDS = 8**

**__init__**(*codegen*, *cfunc*)

**Parameters**
**cfunc** (GoFunction)

**run**()

**class** angr.analyses.decompiler.structured_codegen.go.**ShortDeclarations**

Bases: object

Turn the first assignment of a local into `x := e` when it sits in the innermost block enclosing every use of `x` (Go's scoping for short declarations), and drop the `var` line. Loop initializers and range loops declare their variables the same way.

**__init__**(*codegen*, *cfunc*)

**Parameters**
**cfunc** (GoFunction)

**run**()

class angr.analyses.decompiler.structured_codegen.go.**StringLiteralLengths**

Bases: object

Go string data is not NUL-terminated, so a constant data pointer renders the rest of the string pool. Clip it to the length it travels with: the next word of a struct literal, the next call argument or result, or the length word stored next to it (`x.len = n; x.ptr = p` or two adjacent stack slots).

**__init__**(*codegen*, *cfunc*)

**Parameters**
**cfunc** (GoFunction)

**run**()

class angr.analyses.decompiler.structured_codegen.go.**SelectRecovery**

Bases: *GoStructuredCodeWalker*

`runtime.selectgo(&cases, &order, pc, nsends, nrecvs, block)` with its case records built on the stack and the dispatch on the chosen index becomes `select { case v := <-ch: ... case ch <- x: ... default: ... }`.

**__init__**(*codegen*, *cfunc*)

**Parameters**
**cfunc** (GoFunction)

**run**()

**handle_GoStatements**(*obj*)

class angr.analyses.decompiler.structured_codegen.go.**MakeTypecastsImplicit**

Bases: *GoStructuredCodeWalker*

**classmethod collapse**(*dst_ty*, *child*)

**Return type**
*GoExpression*

**Parameters**

- **dst_ty** (SimType)
- **child** (GoExpression)

**handle_GoAssignment**(*obj*)

**handle_GoFunctionCall**(*obj*)

**Parameters**
**obj** (GoFunctionCall)

**handle_GoReturn**(*obj*)

**Parameters**
**obj** (GoReturn)

**handle_GoBinaryOp**(*obj*)

**Parameters**
**obj** (GoBinaryOp)

**handle_GoTypeCast**(*obj*)

**Parameters**
**obj** (GoTypeCast)

class angr.analyses.decompiler.structured_codegen.go.**FieldReferenceCleanup**

Bases: *GoStructuredCodeWalker*

**handle_GoTypeCast**(*obj*)

class angr.analyses.decompiler.structured_codegen.go.**PointerArithmeticFixer**

Bases: *GoStructuredCodeWalker*

Before calling this fixer class, pointer arithmetics are purely integer-based and ignoring the pointer type.

For example, in the following case:

struct A* a_ptr; // assume struct A is 24 bytes in size a_ptr = a_ptr + 24;

It means adding 24 to the address of a_ptr, without considering the size of struct A. This fixer class will make pointer arithmetics aware of the pointer type. In this case, the fixer class will convert the code to a_ptr = a_ptr + 1.

**handle_GoAssignment**(*obj*)

**Parameters**
**obj** (GoAssignment)

**handle_GoBinaryOp**(*obj*)

**Parameters**
**obj** (GoBinaryOp)

### angr.analyses.decompiler.structured_codegen.go_serialize

Protobuf serialization for the Go AST defined in go.

Same flat indexed node table as c_serialize, and the same Codegen envelope: Codegen.flavor says which class family a node table belongs to, and every node kind shared with C names both a C class and its Go counterpart. Where a Go node's payload matches its C counterpart's, the C serializer writes it.

class angr.analyses.decompiler.structured_codegen.go_serialize.**GoSerializeContext**

Bases: *SerializeContext*

Stores a node under its idx, except when another node already took that idx: a node copied with copy.copy (as ChannelRangeRecovery does) keeps its original's idx, and the two must stay two nodes. Whichever is serialized second gets an id past every idx the codegen has allocated.

**__init__**(*next_free*, *kb=None*)

**Parameters**
**next_free** (*int*)

**Return type**
None

class angr.analyses.decompiler.structured_codegen.go_serialize.**GoParseContext**

Bases: *ParseContext*

Parses a Go node table.

**__init__**(**args*, ***kwargs*)

**Return type**
None

**resolve_type**(*ref*)

Resolve a type-pool ref once; every node referring to it shares the instance, as the live codegen's nodes share their variables' type objects. Library structs come back by name from kb.go_signatures.

**Return type**
*SimType* | None

**Parameters**
**ref** (*int*)

**resolve_function**(*addr*)

**Return type**
*FunctionRef*

**Parameters**
**addr** (*int*)

**parser_for**(*kind*)

**Parameters**
**kind** (*int*)

**set_codegen**(*codegen*)

**Return type**
None

angr.analyses.decompiler.structured_codegen.go_serialize.**serialize_codegen**(*codegen*)

Build a Codegen cmessage from a live GoStructuredCodeGenerator instance.

**Return type**
Codegen

angr.analyses.decompiler.structured_codegen.go_serialize.**parse_codegen**(*msg*, ***, *project=None*, *kb=None*, *func=None*)

Create a GoStructuredCodeGenerator from a Codegen cmessage, bypassing __init__ (which runs the whole decompilation pipeline). The result is suitable for display, navigation, and cache-validity checks; re-rendering needs the runtime back-references (project / func / kb) reattached.

angr.analyses.decompiler.structured_codegen.go_serialize.**rebuild_ast_to_pos**(*pos_to_node*)

Mirror of GoStructuredCodeGenerator.render_text: rebuild map_ast_to_pos from map_pos_to_node.

angr.analyses.decompiler.structured_codegen.go_serialize.**register_all**()

Register serializer/parser pairs for every concrete GoConstruct subclass. Called from go.py at import time, once every class is defined.

**Return type**
None

### angr.analyses.decompiler.structured_codegen.rust

angr.analyses.decompiler.structured_codegen.rust.**unpack_typeref**(*ty*)

angr.analyses.decompiler.structured_codegen.rust.**unpack_pointer**(*ty*)

**Return type**
*SimType* | None

angr.analyses.decompiler.structured_codegen.rust.**unpack_array**(*ty*)

**Return type**
*SimType* | None

angr.analyses.decompiler.structured_codegen.rust.**squash_array_reference**(*ty*)

angr.analyses.decompiler.structured_codegen.rust.**qualifies_for_simple_cast**(*ty1*, *ty2*)

angr.analyses.decompiler.structured_codegen.rust.**qualifies_for_width_cast**(*ty*)

angr.analyses.decompiler.structured_codegen.rust.**qualifies_for_implicit_cast**(*ty1*, *ty2*)

angr.analyses.decompiler.structured_codegen.rust.**extract_terms**(*expr*)

**Return type**
tuple[int, list[tuple[int, *RustExpression*]]]

**Parameters**
**expr** (RustExpression)

angr.analyses.decompiler.structured_codegen.rust.**is_machine_word_size_type**(*type_*, *arch*)

**Return type**
bool

**Parameters**

- **type_** (SimType)
- **arch** (*Arch*)

angr.analyses.decompiler.structured_codegen.rust.**guess_value_type**(*value*, *project*)

**Return type**
*SimType* | None

**Parameters**

- **value** (*float*)
- **project** (*angr.Project*)

angr.analyses.decompiler.structured_codegen.rust.**type_to_rust_repr_chunks**(*ty*, *name=None*, *name_type=None*, *full=False*, *indent_str=''*)

Helper generator function to turn a SimType into generated tuples of (C-string, AST node).

**Parameters**
**ty** (SimType)

**class** angr.analyses.decompiler.structured_codegen.rust.**RustConstruct**

Bases: object

Represents a program construct in C. Acts as the base class for all other representation constructions.

**__init__**(*codegen*)

**codegen:** *RustStructuredCodeGenerator*

**c_repr**(*indent=0*, *pos_to_node=None*, *pos_to_addr=None*, *addr_to_pos=None*)

Creates the C representation of the code and displays it by constructing a large string. This function is called by each program function that needs to be decompiled. The map_pos_to_node and map_pos_to_addr act as position maps for the location of each variable and statement to be tracked for later GUI operations. The map_pos_to_addr also contains expressions that are nested inside of statements.

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**static indent_str**(*indent=0*)

class angr.analyses.decompiler.structured_codegen.rust.**RustFunction**

Bases: *RustConstruct*, *FunctionNode*

Represents a function in Rust.

**__init__**(*addr*, *name*, *functy*, *arg_list*, *statements*, *variables_in_use*, *variable_manager*, *demangled_name=None*, *show_demangled_name=True*, ***kwargs*)

**Parameters**

- **functy** (RustSimTypeFunction)
- **arg_list** (*list*[RustVariable])

**addr**

**name**

**functy**

**arg_list**

**statements**

**variables_in_use**

**variable_manager:** *VariableManagerInternal*

**demangled_name**

**unified_local_vars:** dict[*SimVariable*, list[tuple[*RustVariable*, *SimType*]]]

**show_demangled_name**

**get_unified_local_vars**()

**Return type**
dict[*SimVariable*, list[tuple[*RustVariable*, *SimType*]]]

**variable_list_repr_chunks**(*indent=0*)

**c_repr_chunks**(*indent=0*, *asexpr=False*)

angr.analyses.decompiler.structured_codegen.rust.**UNSUPPORTED_PLACEHOLDER = '/* unsupported instruction */'**

emitted for a construct the backend cannot render; never an AIL or Python repr

class angr.analyses.decompiler.structured_codegen.rust.**RustStatement**

Bases: *RustConstruct*

Represents a statement in C.

class angr.analyses.decompiler.structured_codegen.rust.**RustExpression**

Bases: *RustConstruct*, *ExpressionNode*

Base class for C expressions.

**__init__**(*collapsed=False*, ***kwargs*)

**collapsed**

**property type**

**set_type**(*v*)

class angr.analyses.decompiler.structured_codegen.rust.**RustStatements**

Bases: *RustStatement*

Represents a sequence of statements in C.

**__init__**(*statements*, ***kwargs*)

**statements**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustAILBlock**

Bases: *RustStatement*

Represents a block of AIL statements.

**__init__**(*block*, ***kwargs*)

**block**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustLoop**

Bases: *RustStatement*

Represents a loop in Rust.

class angr.analyses.decompiler.structured_codegen.rust.**RustInfiniteLoop**

Bases: *RustLoop*

Represents an infinite loop in Rust.

**__init__**(*body*, *tags=None*, ***kwargs*)

**body**

**tags**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustWhileLoop**

Bases: *RustLoop*

Represents a while loop in C.

__init__(*condition*, *body*, *tags=None*, ***kwargs*)

condition

body

tags

c_repr_chunks(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.RustDoWhileLoop

Bases: RustLoop

Represents a do-while loop in C.

__init__(*condition*, *body*, *tags=None*, ***kwargs*)

condition

body

tags

c_repr_chunks(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.RustForLoop

Bases: RustStatement

Represents a for-loop in C.

__init__(*initializer*, *condition*, *iterator*, *body*, *tags=None*, ***kwargs*)

initializer

condition

iterator

body

tags

c_repr_chunks(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.RustIfElse

Bases: RustStatement

Represents an if-else construct in Rust.

__init__(*condition_and_nodes*, *else_node=None*, *simplify_else_scope=False*, *cstyle_ifs=True*, *tags=None*, ***kwargs*)

**Parameters**

**condition_and_nodes** (*list[tuple[RustExpression, RustStatement | None]]*)

condition_and_nodes

else_node

simplify_else_scope

**cstyle_ifs**

**tags**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustIfBreak**

Bases: *RustStatement*

Represents an if-break statement in C.

**__init__**(*condition*, *cstyle_ifs=True*, *tags=None*, ***kwargs*)

**condition**

**cstyle_ifs**

**tags**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustBreak**

Bases: *RustStatement*

Represents a break statement in C.

**__init__**(*tags=None*, ***kwargs*)

**tags**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustContinue**

Bases: *RustStatement*

Represents a continue statement in C.

**__init__**(*tags=None*, ***kwargs*)

**tags**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustSwitchCase**

Bases: *RustStatement*

Represents a switch-case statement in C.

**__init__**(*switch*, *cases*, *default*, *tags=None*, ***kwargs*)

**switch**

**cases:** list[tuple[int | tuple[int], *RustStatements*]]

**default**

**tags**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustPatternMatch**

Bases: *RustStatement*

Represents a pattern-match statement in Rust.

**__init__**(*match_expr*, *cases*, *default*, *tags=None*, ***kwargs*)

**scrutinee**

**arms**: list[tuple[tuple[*EnumVariant*, tuple[*RustExpression*, ...]], *RustStatements*]]

**default**

**tags**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustIfLet**

Bases: *RustStatement*

Represents an if let statement in Rust.

**__init__**(*pattern*, *scrutinee*, *true_node*, *false_node*, *tags=None*, ***kwargs*)

**pattern**

**scrutinee**

**true_node**

**false_node**

**tags**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustAssignment**

Bases: *RustStatement*

a = b

**__init__**(*lhs*, *rhs*, *tags=None*, ***kwargs*)

**lhs**

**rhs**

**tags**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustFunctionLikeMacro**

Bases: *RustStatement*, *RustExpression*

**__init__**(*name*, *args*, *delimiter*, *is_expr*, *returnty=None*, *tags=None*, ***kwargs*)

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**property type**

class angr.analyses.decompiler.structured_codegen.rust.**RustFunctionCall**

Bases: *RustStatement*, *RustExpression*, *FunctionCallNode*

func(arg0, arg1)

**Variables**

- **callee_func** (Function) – The function getting called.
- **is_expr** – True if the return value of the function is written to ret_expr; Essentially, ret_expr = call().

**__init__**(*callee_target*, *callee_func*, *args*, *returning=True*, *ret_expr=None*, *receiver=None*, *tags=None*, *is_expr=False*, *show_demangled_name=True*, *show_disambiguated_name=True*, *callsite_prototype=None*, ***kwargs*)

**Parameters**

- **is_expr** (*bool*)
- **show_disambiguated_name** (*bool*)
- **callsite_prototype** (RustSimTypeFunction | *None*)

**callee_target**

**callee_func**: *Function* | None

**args**

**returning**

**ret_expr**

**receiver**

**tags**

**is_expr**

**show_demangled_name**

**show_disambiguated_name**

**callsite_prototype**

property **prototype**: *SimTypeFunction* | None

property **type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**Parameters**

- **indent** – Number of whitespace indentation characters.
- **asexpr** (bool) – True if this call is used as an expression (which means we will skip the generation of semicolons and newlines at the end of the call).

class angr.analyses.decompiler.structured_codegen.rust.**RustReturn**

Bases: *RustStatement*

**__init__**(*retval*, *tags=None*, ***kwargs*)

**retval**

**tags**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustGoto**

Bases: *RustStatement*

**__init__**(*target*, *target_idx*, *tags=None*, ***kwargs*)

**target:** int | *RustExpression*

**target_idx**

**tags**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustUnsupportedStatement**

Bases: *RustStatement*

A wrapper for unsupported AIL statement.

**__init__**(*stmt*, ***kwargs*)

**stmt**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustIncompleteSwitchCase**

Bases: *RustStatement*

An incomplete switch-case construct; only appears in the output when switch-case structuring failed.

**__init__**(*head*, *cases*, *tags=None*, ***kwargs*)

**head**

**cases:** list[tuple[int, *RustStatements*]]

**tags**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustDirtyStatement**

Bases: *RustStatement*

A dirty expression used as a statement, i.e. only for its side effects.

**__init__**(*dirty*, ***kwargs*)

**dirty**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustLabel**

Bases: *RustStatement*, *LabelNode*

Represents a label in C code.

__init__(*name*, *ins_addr*, *block_idx*, *tags=None*, ***kwargs*)

**Parameters**

- **name** (*str*)
- **ins_addr** (*int | None*)
- **block_idx** (*int | None*)

**name**

**ins_addr**

**block_idx**

**tags**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustStruct**

Bases: *RustExpression*

__init__(*name*, *fields*, *field_names*, *tags=None*, ***kwargs*)

**name**

**fields**

**field_names**

**tags**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustEnum**

Bases: *RustExpression*

__init__(*name*, *fields*, *tags=None*, ***kwargs*)

**name**

**fields**

**tags**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustStructField**

Bases: *RustExpression*, *StructFieldNode*

__init__(*struct_type*, *offset*, *field*, *tags=None*, ***kwargs*)

**Parameters**

**struct_type** (SimStruct)

**struct_type**

**offset**

**field**

tags

property type

c_repr_chunks(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustArray**

Bases: *RustExpression*

__init__(*elements*, *tags=None*, ***kwargs*)

elements

tags

c_repr_chunks(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustLet**

Bases: *RustExpression*

__init__(*let_expr*, *tags=None*, ***kwargs*)

**Parameters**
**let_expr** (Let)

let_expr

property variant

property type

c_repr_chunks(*indent=0*, *asexpr=False*)

tags

class angr.analyses.decompiler.structured_codegen.rust.**RustStringLiteral**

Bases: *RustExpression*

__init__(*data*, *tags=None*, ***kwargs*)

data

property type

c_repr_chunks(*indent=0*, *asexpr=False*)

tags

class angr.analyses.decompiler.structured_codegen.rust.**RustFakeVariable**

Bases: *RustExpression*

An uninterpreted name to display in the decompilation output. Pretty much always represents an error?

__init__(*name*, *ty*, *tags=None*, ***kwargs*)

**Parameters**

- **name** (*str*)
- **ty** (SimType)

name

**tags**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.rust.**RustVariable**

Bases: *RustExpression*, *VariableNode*

CVariable represents access to a variable with the specified type (*variable_type*).

*variable* must be a SimVariable.

**__init__**(*variable*, *unified_variable=None*, *variable_type=None*, *tags=None*, ***kwargs*)

**Parameters**
**variable** (SimVariable)

**variable:** *SimVariable*

**unified_variable:** *SimVariable* | None

**variable_type:** *SimType*

**tags**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.rust.**RustIndexedVariable**

Bases: *RustExpression*, *IndexedVariableNode*

Represent a variable (an array) that is indexed.

**__init__**(*variable*, *index*, *variable_type=None*, *tags=None*, ***kwargs*)

**Parameters**

- **variable** (RustExpression)
- **index** (RustExpression)

**index:** *RustExpression*

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**collapsed**

**class** angr.analyses.decompiler.structured_codegen.rust.**RustVariableField**

Bases: *RustExpression*, *VariableFieldNode*

Represent a field of a variable.

**__init__**(*variable*, *field*, *var_is_ptr=False*, *tags=None*, ***kwargs*)

**Parameters**

- **variable** (RustExpression)
- **field** (RustStructField)
- **var_is_ptr** (*bool*)

property type

c_repr_chunks(*indent=0*, *asexpr=False*)

collapsed

class angr.analyses.decompiler.structured_codegen.rust.**RustUnaryOp**

Bases: *RustExpression*, *UnaryOpNode*

Unary operations.

__init__(*op*, *operand*, *tags=None*, ***kwargs*)

**Parameters**
**operand** (RustExpression)

op

operand

tags

property type

c_repr_chunks(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustBinaryOp**

Bases: *RustExpression*, *BinaryOpNode*

Binary operations.

__init__(*op*, *lhs*, *rhs*, *tags=None*, ***kwargs*)

op

lhs

rhs

tags

common_type

static compute_common_type(*op*, *lhs_ty*, *rhs_ty*)

**Return type**
*SimType*

**Parameters**

- **op** (*str*)
- **lhs_ty** (SimType)
- **rhs_ty** (SimType)

property type

property op_precedence

c_repr_chunks(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustTypeCast**

Bases: *RustExpression*

**__init__**(*src_type*, *dst_type*, *expr*, *tags=None*, ***kwargs*)

**Parameters**

- **src_type** (SimType | *None*)
- **dst_type** (SimType)
- **expr** (RustExpression)

**src_type**

**dst_type**

**expr**

**tags**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustConstant**

Bases: *RustExpression*, *ConstantNode*

**__init__**(*value*, *type_*, *reference_values=None*, *tags=None*, ***kwargs*)

**Parameters**

- **type_** (SimType)
- **tags** (*dict* | *None*)

**value**

**reference_values**

**tags**

**property fmt**

**property fmt_hex**

**property fmt_neg**

**property fmt_char**

**Setter accepts**
bool

**property type**

**static str_to_rust_str**(*_str*, *is_heap_str=False*, *prefix=''*)

**Parameters**
**prefix** (*str*)

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**fmt_int**(*value*)

Format an integer using the format setup of the current node.

**Parameters**
**value** (int) – The integer value to format.

**Return type**
str

**Returns**
The formatted string.

**class** angr.analyses.decompiler.structured_codegen.rust.**RustRegister**

Bases: *RustExpression*

**__init__**(*reg*, *tags=None*, ***kwargs*)

**Parameters**
**reg** (*str*)

**reg**

**tags**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.rust.**RustITE**

Bases: *RustExpression*

**__init__**(*cond*, *iftrue*, *iffalse*, *tags=None*, ***kwargs*)

**cond**

**iftrue**

**iffalse**

**tags**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.rust.**RustMultiStatementExpression**

Bases: *RustExpression*

(stmt0, stmt1, stmt2, expr)

**__init__**(*stmts*, *expr*, *tags=None*, ***kwargs*)

**Parameters**

- **stmts** (RustStatements)
- **expr** (RustExpression)

**stmts**

**expr**

**tags**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.rust.**RustVEXCCallExpression**

Bases: *RustExpression*

ccall_name(arg0, arg1, ...)

**__init__**(*callee*, *operands*, *tags=None*, ***kwargs*)

**Parameters**

- **callee** (*str*)
- **operands** (*list[RustExpression]*)

**callee**

**operands**

**tags**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.rust.**RustVectorConvert**

Bases: *RustExpression*

A lane-wise conversion (an AIL Convert with vector_count), rendered as an intrinsic-style call.

**__init__**(*expr*, *operand*, ***kwargs*)

**Parameters**

- **expr** (Convert)
- **operand** (RustExpression)

**expr**

**operand**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

**class** angr.analyses.decompiler.structured_codegen.rust.**RustDirtyExpression**

Bases: *RustExpression*

Ideally all dirty expressions should be handled and converted to proper conversions during conversion from VEX to AIL. Eventually this class should not be used at all.

**__init__**(*dirty*, *operands=None*, ***kwargs*)

**Parameters**

**operands** (*list[RustExpression] | None*)

**dirty**

**operands**

**property type**

**c_repr_chunks**(*indent=0*, *asexpr=False*)

class angr.analyses.decompiler.structured_codegen.rust.**RustClosingObject**

Bases: *ClosingObjectNode*

A class to represent all objects that can be closed by it's correspodning character. Examples: (), {}, []

**__init__**(*opening_symbol*)

**opening_symbol**

class angr.analyses.decompiler.structured_codegen.rust.**RustArrayTypeLength**

Bases: object

A class to represent the type information of fixed-size array lengths. Examples: In "char foo[20]", this would be the "[20]".

**__init__**(*text*)

**text**

class angr.analyses.decompiler.structured_codegen.rust.**RustStructFieldNameDef**

Bases: object

A class to represent the name of a defined field in a struct. Needed because it's not a CVariable or a CStructField (because CStructField is the access of a CStructField). Example: In "struct foo { int bar; }, this would be "bar".

**__init__**(*name*)

**name**

class angr.analyses.decompiler.structured_codegen.rust.**RustStructuredCodeGenerator**

Bases: *BaseStructuredCodeGenerator*, *Analysis*

**__init__**(*func*, *sequence*, *indent=0*, *cfg=None*, *func_args=None*, *binop_depth_cutoff=16*, *show_casts=True*, *braces_on_own_lines=False*, *use_compound_assignments=True*, *show_local_types=False*, *comment_gotos=False*, *cstyle_null_cmp=True*, *flavor=None*, *stmt_comments=None*, *expr_comments=None*, *show_externs=False*, *externs=None*, *const_formats=None*, *show_demangled_name=True*, *show_disambiguated_name=True*, *ail_graph=None*, *simplify_else_scope=True*, *cstyle_ifs=True*, *omit_func_header=False*, *display_block_addrs=False*, *display_vvar_ids=False*, *min_data_addr=4194304*, *notes=None*, *display_notes=True*, *max_str_len=None*, *prettify_thiscall=False*, *cstyle_void_param=True*, *indent_size=4*, *variable_map=None*, *stl_accessor_calls=False*)

**Parameters**

- **func_args** (*list[SimVariable] | None*)
- **binop_depth_cutoff** (*int*)
- **min_data_addr** (*int*)
- **display_notes** (*bool*)
- **max_str_len** (*int | None*)
- **prettify_thiscall** (*bool*)
- **cstyle_void_param** (*bool*)

- **indent_size** (*int*)
- **variable_map** (VariableMap | *None*)
- **stl_accessor_calls** (*bool*)

**ailexpr2cnode:** dict[tuple[*Expression*, bool], *RustExpression*] | None

**cnode2ailexpr:** dict[*RustExpression*, *Expression*] | None

**expr_comments:** dict[int, str]

**stmt_comments:** dict[int, str]

**const_formats:** dict[Any, dict[str, Any]]

**map_ast_to_pos:** dict[*SimVariable*, set[*PositionMappingElement*]] | None

**map_addr_to_label:** dict[tuple[int | None, int | None], *RustLabel*]

**rust_func:** *RustFunction* | None

**cexterns:** set[*RustVariable*] | None

**reapply_options**(*options*)

**cleanup**()

Remove existing rendering results.

**regenerate_text**()

Re-render text and re-generate all sorts of mapping information.

**Return type**
None

**RENDER_TYPE**

alias of tuple[str, *PositionMapping*, *PositionMapping*, *InstructionMapping*, dict[Any, set[Any]]]

**render_text**(*rust_func*)

**Return type**
tuple[str, *PositionMapping*, *PositionMapping*, *InstructionMapping*, dict[Any, set[Any]]]

**Parameters**
**rust_func** (RustFunction)

**render_notes**()

Render decompilation notes.

**Return type**
str

**Returns**
A string containing all notes.

**reload_variable_types**()

**Return type**
None

default_simtype_from_size(*n*, *signed=True*)

**Return type**
*RustSimTypeInt*

**Parameters**

- **n** (*int*)
- **signed** (*bool*)

class angr.analyses.decompiler.structured_codegen.rust.**RustStructuredCodeWalker**

Bases: object

classmethod handle(*obj*)

classmethod handle_default(*obj*)

classmethod handle_RustFunction(*obj*)

classmethod handle_RustStatements(*obj*)

classmethod handle_RustWhileLoop(*obj*)

classmethod handle_RustInfiniteLoop(*obj*)

classmethod handle_RustDoWhileLoop(*obj*)

classmethod handle_RustForLoop(*obj*)

classmethod handle_RustIfElse(*obj*)

classmethod handle_RustIfBreak(*obj*)

classmethod handle_RustSwitchCase(*obj*)

classmethod handle_RustAssignment(*obj*)

classmethod handle_RustFunctionCall(*obj*)

classmethod handle_RustReturn(*obj*)

classmethod handle_RustGoto(*obj*)

classmethod handle_RustIndexedVariable(*obj*)

classmethod handle_RustVariableField(*obj*)

classmethod handle_RustUnaryOp(*obj*)

classmethod handle_RustBinaryOp(*obj*)

classmethod handle_RustTypeCast(*obj*)

classmethod handle_RustITE(*obj*)

classmethod handle_RustVectorConvert(*obj*)

classmethod handle_RustVEXCCallExpression(*obj*)

class angr.analyses.decompiler.structured_codegen.rust.**MakeTypecastsImplicit**

Bases: *RustStructuredCodeWalker*

**classmethod collapse**(*dst_ty*, *child*)

**Return type**
*RustExpression*

**Parameters**

- **dst_ty** (SimType | *None*)
- **child** (RustExpression)

**classmethod handle_RustAssignment**(*obj*)

**classmethod handle_RustFunctionCall**(*obj*)

**Parameters**
**obj** (RustFunctionCall)

**classmethod handle_RustReturn**(*obj*)

**Parameters**
**obj** (RustReturn)

**classmethod handle_RustBinaryOp**(*obj*)

**Parameters**
**obj** (RustBinaryOp)

**classmethod handle_RustTypeCast**(*obj*)

**Parameters**
**obj** (RustTypeCast)

**class** angr.analyses.decompiler.structured_codegen.rust.**FieldReferenceCleanup**

Bases: *RustStructuredCodeWalker*

**classmethod handle_RustTypeCast**(*obj*)

**class** angr.analyses.decompiler.structured_codegen.rust.**PointerArithmeticFixer**

Bases: *RustStructuredCodeWalker*

Before calling this fixer class, pointer arithmetics are purely integer-based and ignoring the pointer type.

For example, in the following case:

struct A* a_ptr; // assume struct A is 24 bytes in size a_ptr = a_ptr + 24;

It means adding 24 to the address of a_ptr, without considering the size of struct A. This fixer class will make pointer arithmetics aware of the pointer type. In this case, the fixer class will convert the code to a_ptr = a_ptr + 1.

**classmethod handle_RustBinaryOp**(*obj*)

**Parameters**
**obj** (RustBinaryOp)

### angr.analyses.decompiler.structured_codegen.sse_intrinsics

Intel-intrinsics view of 128-bit SSE vector AIL: lane kinds of variables, `_mm_*` names of lane-wise ops, and the `pshufd` lane shuffles that VEX spells out as CONCAT trees of 32-bit lane extractions.

angr.analyses.decompiler.structured_codegen.sse_intrinsics.**is_vector_op**(*expr*)

A lane-wise BinaryOp over a full 128-bit vector.

**Return type**
TypeGuard[*BinaryOp*]

**Parameters**
**expr** (Expression)

angr.analyses.decompiler.structured_codegen.sse_intrinsics.**vector_op_kind**(*expr*)

**Return type**
Literal['int', 'float', 'double']

**Parameters**
**expr** (BinaryOp)

angr.analyses.decompiler.structured_codegen.sse_intrinsics.**vector_op_intrinsic**(*expr*)

(intrinsic name, swap operands, operand lane bits) of a lane-wise op, or None when no intrinsic matches exactly.

**Return type**
tuple[str, bool, int] | None

**Parameters**
**expr** (BinaryOp)

angr.analyses.decompiler.structured_codegen.sse_intrinsics.**lane_of**(*expr*, *lane_bits*, *any_offset=False*)

(vector, bit offset) when *expr* reads one *lane_bits*-wide, lane-aligned lane of a 128-bit vector through truncations and logical right shifts, e.g. `(uint32_t)((uint64_t)v >> 32)` is lane 1 of v. With *any_offset*, *expr* may be wider than the lane, and the offset need not be lane-aligned.

**Return type**
tuple[*Expression*, int] | None

**Parameters**

- **expr** (Expression)
- **lane_bits** (*int*)
- **any_offset** (*bool*)

angr.analyses.decompiler.structured_codegen.sse_intrinsics.**concat_constant**(*expr*)

The value of a Concat tree of integer constants, or None.

**Return type**
int | None

**Parameters**
**expr** (BinaryOp)

angr.analyses.decompiler.structured_codegen.sse_intrinsics.**match_shuffle_epi32**(*expr*)

(vector, imm8) when a 128-bit Concat tree picks the four 32-bit lanes of one vector: pshufd.

**Return type**
tuple[*Expression*, int] | None

**Parameters**
**expr** (BinaryOp)

**class** angr.analyses.decompiler.structured_codegen.sse_intrinsics.**SSEVectorTyping**

Bases: object

Lane kinds of 128-bit variables: seeded by the lane-wise ops that read or write them and propagated through copies and full-width bitwise ops.

**Parameters**

- **variable_key** (Callable[[*Expression* | *Statement*], *SimVariable* | None]) – Maps an AIL expression to the (unified) variable it denotes, or None.
- **eligible** (Callable[[*SimVariable*], bool]) – Whether a variable may be retyped as a vector (its current type is a 128-bit integer).

**__init__**(*variable_key*, *eligible*)

**Parameters**

- **variable_key** (*Callable[[Expression | Statement], SimVariable | None]*)
- **eligible** (*Callable[[SimVariable], bool]*)

**kind**(*expr*)

The lane kind of a 128-bit expression, or None if it does not look like a vector.

**Return type**
Optional[Literal['int', 'float', 'double']]

**Parameters**
**expr** (Expression)

**collect**(*blocks*)

**Return type**
None

**Parameters**
**blocks** (*Iterable[Block]*)

## angr.analyses.decompiler.structured_codegen.utils

angr.analyses.decompiler.structured_codegen.utils.**first_stmt_addr**(*statements*)

The address of the first statement that has one: a nested statement list's address or an instruction address tag.

**Return type**
int | None

**Parameters**
**statements** (*Sequence[CStatement] | Sequence[GoStatement]*)

## angr.analyses.decompiler.structurer_nodes

**exception** angr.analyses.decompiler.structurer_nodes.**EmptyBlockNotice**

Bases: Exception

**class** angr.analyses.decompiler.structurer_nodes.**MultiNode**

Bases: object

**__init__**(*nodes*, *addr=None*, *idx=None*)

**Parameters**

- **nodes** (*Iterable[Block]*)
- **addr** (*int | None*)
- **idx** (*int | None*)

**nodes:** list[Block]

**addr**

**idx**

**copy**()

**Return type**
*MultiNode*

**dbg_repr**(*indent=0*)

**Return type**
str

class angr.analyses.decompiler.structurer_nodes.**BaseNode**

Bases: object

**__init__**(*addr*)

**Parameters**
**addr** (*int*)

**addr**

**static test_empty_node**(*node*)

**static test_empty_condition_node**(*cond_node*)

**dbg_repr**(*indent=0*)

class angr.analyses.decompiler.structurer_nodes.**SequenceNode**

Bases: *BaseNode*

**__init__**(*addr*, *nodes=None*)

**Parameters**
**addr** (*int*)

**nodes**

**add_node**(*node*)

**Parameters**

- **switch_expr** (Expression)
- **cases** (*OrderedDict[int | tuple[int, ...], SequenceNode]*)
- **addr** (*int | None*)

**switch_expr**

**cases:** OrderedDict[int | tuple[int, ...], *SequenceNode*]

**default_node**

**dbg_repr**(*indent=0*)

**Return type**
str

class angr.analyses.decompiler.structurer_nodes.**IncompleteSwitchCaseNode**

Bases: *BaseNode*

Describes an incomplete set of switch-case nodes. Usually an intermediate result. Should always be restructured into a SwitchCaseNode by the end of structuring. Only used in Phoenix structurer.

**__init__**(*addr*, *head*, *cases*)

**Parameters**
**cases** (*list*)

**head**

**cases:** list

class angr.analyses.decompiler.structurer_nodes.**IncompleteSwitchCaseHeadStatement**

Bases: *Statement*

Describes a switch-case head. This is only created by LoweredSwitchSimplifier.

**kind = 'IncompleteSwitchCaseHead'**

**pykind = 'IncompleteSwitchCaseHead'**

**__init__**(*idx*, *switch_variable*, *case_addrs*, *peephole_optimized=False*, ***kwargs*)

**Parameters**
**peephole_optimized** (*bool*)

**switch_variable**

**case_addrs:** list[tuple[Block, int | str, int, int, int]]

**peephole_optimized**

**replace**(*old_expr*, *new_expr*)

**property depth:** int

**addr**

**likes**(*other*)

**matches**(*other*)

### angr.analyses.decompiler.structuring

angr.analyses.decompiler.structuring.**DEFAULT_STRUCTURER**

alias of *SAILRStructurer*

**class** angr.analyses.decompiler.structuring.**DreamStructurer**

Bases: *StructurerBase*

Structure a region using a structuring algorithm that is similar to the one in Dream decompiler (described in the "no more gotos" paper). Note that this implementation has quite a few improvements over the original described version and *should not* be used to evaluate the performance of the original algorithm described in that paper.

The current function graph is provided so that we can detect certain edge cases, for example, jump table entries no longer exist due to empty node removal during structuring or prior steps.

**NAME = 'dream'**

**SUPPORTS_OVERLAYS = True**

**__init__**(*region*, *parent_map=None*, *condition_processor=None*, *func=None*, *case_entry_to_switch_head=None*, *parent_region=None*, ***kwargs*)

**Parameters**

- **func** (Function | *None*)
- **case_entry_to_switch_head** (*dict[int, int] | None*)

**class** angr.analyses.decompiler.structuring.**PhoenixStructurer**

Bases: *StructurerBase*

Structure a region using a structuring algorithm that is similar to the one in Phoenix decompiler (described in the "phoenix decompiler" paper). Note that this implementation has quite a few improvements over the original described version and *should not* be used to evaluate the performance of the original algorithm described in that paper.

**NAME = 'phoenix'**

**SUPPORTS_OVERLAYS = True**

**__init__**(*region*, *parent_map=None*, *condition_processor=None*, *func=None*, *case_entry_to_switch_head=None*, *parent_region=None*, *improve_algorithm=False*, *use_multistmtexprs=MultiStmtExprMode.MAX_ONE_CALL*, *multistmtexpr_stmt_threshold=5*, ***kwargs*)

**Parameters**

- **func** (Function | *None*)
- **case_entry_to_switch_head** (*dict[int, int] | None*)
- **use_multistmtexprs** (MultiStmtExprMode)
- **multistmtexpr_stmt_threshold** (*int*)

**replace_nodes_both**(*old_node_0*, *new_node*, *old_node_1=None*, *self_loop=True*, *drop_refinement_marks=False*)

Replace one or two nodes with a new node in the region: the member view, the with-successors view, and the complete graph are all updated by the single overlay operation. If `old_node_1` is a successor of the region rather than a member, it is absorbed into the new node in this region's views only.

**Parameters**
**drop_refinement_marks** (*bool*)

**static dump_graph**(*graph*, *path*)

**Return type**
None

**Parameters**

- **graph** (*DiGraph*)
- **path** (*str*)

**static switch_case_entry_node_has_common_successor_case_1**(*graph*, *jump_table*, *case_nodes*, *node_pred*)

**Return type**
bool

**static switch_case_entry_node_has_common_successor_case_2**(*graph*, *jump_table*, *case_nodes*, *node_pred*)

**Return type**
bool

**class** angr.analyses.decompiler.structuring.**RecursiveStructurer**

Bases: *Analysis*

Recursively structure a region and all of its subregions.

**__init__**(*region*, *cond_proc=None*, *func=None*, *structurer_cls=None*, ***, *ail_manager*, ***kwargs*)

**Parameters**

- **func** (Function | *None*)
- **structurer_cls** (type | *None*)
- **ail_manager** (*Manager*)

**class** angr.analyses.decompiler.structuring.**SAILRStructurer**

Bases: *PhoenixStructurer*

The SAILR structuring algorithm is the phoenix-based algorithm from the USENIX 2024 paper SAILR. The entirety of the algorithm is implemented across this class and various optimization passes in the decompiler. To find each optimization class, simply search for optimizations which reference this class.NAME.

At a high-level, SAILR does three things different from the traditional Phoenix schema-based algorithm:

1. It recursively structures the graph, rather than doing it in a single pass. This allows decisions to be made based on the current state of what the decompilation would look like.
2. It performs deoptimizations targeting specific optimizations that introduces gotos and mis-structured code. It can only do this because of the recursive nature of the algorithm.
3. It uses a more advanced heuristic for virtualizing edges, which is implemented in this class.

Additionally, some changes in Phoenix are only activated when SAILR is used.

**NAME = 'sailr'**

**__init__**(*region*, *improve_phoenix=True*, *postdom_max_edges=10*, *postdom_max_graph_size=50*, ***kwargs*)

angr.analyses.decompiler.structuring.**structurer_class_from_name**(*name*)

**Return type**
type | None

**Parameters**
**name** (*str*)

### Submodules

*dream*
*phoenix*
*recursive_structurer*
*sailr*
*structurer_base*

### angr.analyses.decompiler.structuring.dream

**class** angr.analyses.decompiler.structuring.dream.**DreamStructurer**

Bases: *StructurerBase*

Structure a region using a structuring algorithm that is similar to the one in Dream decompiler (described in the "no more gotos" paper). Note that this implementation has quite a few improvements over the original described version and *should not* be used to evaluate the performance of the original algorithm described in that paper.

The current function graph is provided so that we can detect certain edge cases, for example, jump table entries no longer exist due to empty node removal during structuring or prior steps.

**NAME: str = 'dream'**

**SUPPORTS_OVERLAYS = True**

**__init__**(*region*, *parent_map=None*, *condition_processor=None*, *func=None*, *case_entry_to_switch_head=None*, *parent_region=None*, ***kwargs*)

**Parameters**

- **func** (*Function | None*)
- **case_entry_to_switch_head** (*dict[int, int] | None*)

### angr.analyses.decompiler.structuring.phoenix

**exception** angr.analyses.decompiler.structuring.phoenix.**GraphChangedNotification**

Bases: Exception

A notification for graph that is currently worked on being changed. Once this notification is caught, the graph schema matching process for the current region restarts.

**class** angr.analyses.decompiler.structuring.phoenix.**MultiStmtExprMode**

Bases: StrEnum

Mode of multi-statement expression creation during structuring.

**NEVER = 'Never'**

**ALWAYS = 'Always'**

**MAX_ONE_CALL = 'Only when less than one call'**

**__new__**(*value*)

**class** angr.analyses.decompiler.structuring.phoenix.**PhoenixStructurer**

Bases: *StructurerBase*

Structure a region using a structuring algorithm that is similar to the one in Phoenix decompiler (described in the "phoenix decompiler" paper). Note that this implementation has quite a few improvements over the original described version and *should not* be used to evaluate the performance of the original algorithm described in that paper.

**NAME: str = 'phoenix'**

**SUPPORTS_OVERLAYS = True**

**__init__**(*region*, *parent_map=None*, *condition_processor=None*, *func=None*, *case_entry_to_switch_head=None*, *parent_region=None*, *improve_algorithm=False*, *use_multistmtexprs=MultiStmtExprMode.MAX_ONE_CALL*, *multistmtexpr_stmt_threshold=5*, ***kwargs*)

**Parameters**

- **func** (*Function | None*)
- **case_entry_to_switch_head** (*dict[int, int] | None*)
- **use_multistmtexprs** (*MultiStmtExprMode*)
- **multistmtexpr_stmt_threshold** (*int*)

**whitelist_edges: set[tuple[int, int]]**

**switch_case_known_heads: set[Block | *BaseNode*]**

**dowhile_known_tail_nodes: set**

**replace_nodes_both**(*old_node_0*, *new_node*, *old_node_1=None*, *self_loop=True*, *drop_refinement_marks=False*)

Replace one or two nodes with a new node in the region: the member view, the with-successors view, and the complete graph are all updated by the single overlay operation. If `old_node_1` is a successor of the region rather than a member, it is absorbed into the new node in this region's views only.

**Parameters**

**drop_refinement_marks** (*bool*)

**static dump_graph**(*graph*, *path*)

**Return type**

None

**Parameters**

- **graph** (*DiGraph*)
- **path** (*str*)

**static switch_case_entry_node_has_common_successor_case_1**(*graph*, *jump_table*, *case_nodes*, *node_pred*)

**Return type**

bool

static switch_case_entry_node_has_common_successor_case_2(*graph*, *jump_table*, *case_nodes*, *node_pred*)

**Return type**
bool

### angr.analyses.decompiler.structuring.recursive_structurer

class angr.analyses.decompiler.structuring.recursive_structurer.**RecursiveStructurer**

Bases: *Analysis*

Recursively structure a region and all of its subregions.

__init__(*region*, *cond_proc=None*, *func=None*, *structurer_cls=None*, ***, *ail_manager*, ***kwargs*)

**Parameters**

- **func** (Function | *None*)
- **structurer_cls** (type | *None*)
- **ail_manager** (*Manager*)

### angr.analyses.decompiler.structuring.sailr

class angr.analyses.decompiler.structuring.sailr.**SAILRStructurer**

Bases: *PhoenixStructurer*

The SAILR structuring algorithm is the phoenix-based algorithm from the USENIX 2024 paper SAILR. The entirety of the algorithm is implemented across this class and various optimization passes in the decompiler. To find each optimization class, simply search for optimizations which reference this class.NAME.

At a high-level, SAILR does three things different from the traditional Phoenix schema-based algorithm:

1. It recursively structures the graph, rather than doing it in a single pass. This allows decisions to be made based on the current state of what the decompilation would look like.
2. It performs deoptimizations targeting specific optimizations that introduces gotos and mis-structured code. It can only do this because of the recursive nature of the algorithm.
3. It uses a more advanced heuristic for virtualizing edges, which is implemented in this class.

Additionally, some changes in Phoenix are only activated when SAILR is used.

**NAME: str = 'sailr'**

__init__(*region*, *improve_phoenix=True*, *postdom_max_edges=10*, *postdom_max_graph_size=50*, ***kwargs*)

### angr.analyses.decompiler.structuring.structurer_base

class angr.analyses.decompiler.structuring.structurer_base.**StructurerBase**

Bases: *Analysis*

The base class for analysis passes that structures a region.

The current function graph is provided so that we can detect certain edge cases, for example, jump table entries no longer exist due to empty node removal during structuring or prior steps.

**NAME: str = 'StructurerBase'**

**__init__**(*region*, *parent_map=None*, *condition_processor=None*, *func=None*, *case_entry_to_switch_head=None*, *parent_region=None*, *jump_tables=None*, *ail_manager=None*, ***kwargs*)

**Parameters**

- **func** (*Function | None*)
- **case_entry_to_switch_head** (*dict[int, int] | None*)
- **jump_tables** (*dict[int, IndirectJump] | None*)
- **ail_manager** (*Manager | None*)

**static remove_redundant_jumps**(*seq*, *ail_manager*)

Remove all redundant jumps.

**Parameters**

- **seq** (SequenceNode) – The SequenceNode instance to handle.
- **ail_manager** (Manager) – The AIL manager to create new atoms if needed.

**Returns**

A processed SequenceNode.

**replace_nodes**(*graph*, *old_node_0*, *new_node*, *old_node_1=None*, *self_loop=True*)

**static replace_node_in_node**(*parent_node*, *old_node*, *new_node*)

**Return type**

None

**Parameters**

- **parent_node** (BaseNode)
- **old_node** (BaseNode | *Block* | MultiNode)
- **new_node** (BaseNode | *Block* | MultiNode)

**static is_a_jump_target**(*stmt*, *addr*)

**Return type**

bool

**Parameters**

- **stmt** (ConditionalJump | Jump | Statement)
- **addr** (*int*)

**static has_nonlabel_nonphi_statements**(*node*)

**Return type**

bool

**Parameters**

**node** (BaseNode)

### angr.analyses.decompiler.utils

angr.analyses.decompiler.utils.**const_with_value**(*expr*, *value*)

Return a copy of `expr` carrying `value`. AIL expressions must not be mutated in place: attribute access on a statement returns a fresh wrapper, so `stmt.target.value = x` silently updates a throwaway copy.

**Return type**
*Const*

**Parameters**

- **expr** (Const)
- **value** (*int*)

angr.analyses.decompiler.utils.**copy_expr_with_tags**(*expr*, ***tags*)

Return a copy of expr (same idx) with tags merged in.

Note that *stmt.src.tags[k] = v* is a no-op because stmt.src returns a fresh copy of the expression.

**Return type**
*Expression*

**Parameters**
**expr** (Expression)

angr.analyses.decompiler.utils.**update_jump_target**(*stmt*, *old_addr*, *new_addr*)

Update a Jump statement from old_addr to new_addr through the statement setter. Returns True if the update succeeded.

**Return type**
bool

**Parameters**

- **stmt** (Jump)
- **old_addr** (*int*)
- **new_addr** (*int*)

angr.analyses.decompiler.utils.**update_conditional_jump_target**(*stmt*, *old_addr*, *new_addr*)

Update every branch of a ConditionalJump that points to `old_addr` so it points to `new_addr`. Returns True if any branch was updated.

**Return type**
bool

**Parameters**

- **stmt** (ConditionalJump)
- **old_addr** (*int*)
- **new_addr** (*int*)

angr.analyses.decompiler.utils.**update_jump_target_idx**(*block*, *addr*, *old_idx*, *new_idx*)

Retarget the last statement of `block` (a Jump or ConditionalJump) from block (`addr`, `old_idx`) to block (`addr`, `new_idx`). `old_idx` of None matches any index. Call it whenever an edge is redirected to a copy of its target block, or the jump keeps naming the original block. Returns True if a target was updated.

The statement is replaced, not mutated: graph copies share statement objects, and a pass whose result is discarded must not leave the retargeted jump behind in the original graph.

**Return type**
bool

**Parameters**

- **block** (*Block*)
- **addr** (*int*)
- **old_idx** (*int | None*)
- **new_idx** (*int*)

angr.analyses.decompiler.utils.**set_conditional_jump_targets**(*stmt*, *true_addr*, *false_addr*)

Point the branches of a ConditionalJump (with constant targets) at `true_addr` and `false_addr`.

**Return type**
None

**Parameters**

- **stmt** (ConditionalJump)
- **true_addr** (*int*)
- **false_addr** (*int*)

angr.analyses.decompiler.utils.**remove_last_statement**(*node*)

angr.analyses.decompiler.utils.**remove_last_statements**(*node*)

**Return type**
bool

angr.analyses.decompiler.utils.**append_statement**(*node*, *stmt*)

angr.analyses.decompiler.utils.**replace_last_statement**(*node*, *old_stmt*, *new_stmt*)

angr.analyses.decompiler.utils.**extract_jump_targets**(*stmt*)

Extract concrete goto targets from a Jump or a ConditionalJump statement.

**Parameters**
**stmt** – The statement to analyze.

**Returns**
A list of known concrete jump targets.

**Return type**
list

angr.analyses.decompiler.utils.**switch_extract_cmp_bounds**(*last_stmt*)

Check the last statement of the switch-case header node, and extract lower+upper bounds for the comparison.

**Parameters**
**last_stmt** (*ConditionalJump* | *Statement*) – The last statement of the switch-case header node.

**Return type**
tuple[Any, int, int] | None

**Returns**
A tuple of (comparison expression, lower bound, upper bound), or None

angr.analyses.decompiler.utils.**switch_extract_cmp_bounds_from_condition**(*cond*)

**Return type**
tuple[Any, int, int] | None

**Parameters**
**cond** (Expression)

angr.analyses.decompiler.utils.**switch_extract_switch_expr_from_jump_target**(*target*)

Extract the switch expression from the indirect jump target expression.

**Parameters**
**target** (*Expression*) – The target of the indirect jump statement.

**Return type**
*Expression* | None

**Returns**
The extracted expression if successful, or None otherwise.

angr.analyses.decompiler.utils.**switch_extract_bitwiseand_jumptable_info**(*last_stmt*)

Check the last statement of the switch-case header node (whose address is loaded from a jump table and computed using an index) and extract necessary information for rebuilding the switch-case construct.

An example of the statement:

```
Goto(Conv(32->s64, (
    Load(addr=(0x4530e4<64> + (Conv(32->64, (Conv(64->32, vvar_287{reg 32}) & 0x3
↪<32>)) * 0x4<64>)),
         size=4, endness=Iend_LE) + 0x4530e4<32>))
)
```

Another example:

```
Load(addr=(((vvar_9{reg 36} & 0x3<32>) * 0x4<32>) + 0x42cd28<32>), size=4,␣
↪endness=Iend_LE)
```

Logical right shifts also bound unsigned indexes. For example, `status() >> 31` on a 32-bit value selects one of two entries. Keep the bounded expression intact, including any calls it contains.

**Parameters**
**last_stmt** (*Jump*) – The last statement of the switch-case header node.

**Return type**
tuple[*Any*, int, int | None] | None

A niche-decoded index (see `_is_niche_decoded_index`) is bounded only by the jump table itself, so its upper bound is None.

**Return type**
tuple[Any, int, int | None] | None

**Returns**
A tuple of `(index expression, lower bound, upper bound)`, or None.

**Parameters**
**last_stmt** (Jump)

angr.analyses.decompiler.utils.**get_ast_subexprs**(*claripy_ast*)

angr.analyses.decompiler.utils.**insert_node**(*parent*, *insert_location*, *node*, *node_idx*, *label=None*)

**Parameters**

- **insert_location** (*str*)
- **node_idx** (*int*)

angr.analyses.decompiler.utils.**to_ail_supergraph**(*transition_graph*, *allow_fake=False*)

Takes an AIL graph and converts it into a AIL graph that treats calls and redundant jumps as parts of a bigger block instead of transitions. Calls to returning functions do not terminate basic blocks.

Based on region_identifier super_graph

**Return type**
DiGraph

**Returns**
A converted super transition graph

**Parameters**
**transition_graph** (*DiGraph*)

angr.analyses.decompiler.utils.**is_empty_node**(*node*)

**Return type**
bool

angr.analyses.decompiler.utils.**is_empty_or_label_only_node**(*node*)

**Return type**
bool

angr.analyses.decompiler.utils.**has_nonlabel_statements**(*block*)

**Return type**
bool

**Parameters**
**block** (*Block*)

angr.analyses.decompiler.utils.**has_nonlabel_nonphi_statements**(*block*)

**Return type**
bool

**Parameters**
**block** (*Block*)

angr.analyses.decompiler.utils.**first_nonlabel_statement**(*block*)

**Return type**
*Statement* | None

**Parameters**
**block** (*Block* | MultiNode)

angr.analyses.decompiler.utils.**first_nonlabel_statement_id**(*block*)

**Return type**
int | None

**Parameters**
**block** (*Block*)

angr.analyses.decompiler.utils.**first_nonlabel_nonphi_statement**(*block*)

**Return type**
*Statement* | None

**Parameters**
**block** (*Block* | MultiNode)

angr.analyses.decompiler.utils.**last_nonlabel_statement**(*block*)

**Return type**
*Statement* | None

**Parameters**
**block** (*Block*)

angr.analyses.decompiler.utils.**last_node**(*node*)

Get the last node in a sequence or code node.

**Return type**
*BaseNode* | Block | None

**Parameters**
**node** (BaseNode | *Block*)

angr.analyses.decompiler.utils.**first_nonlabel_node**(*seq*)

**Return type**
*BaseNode* | Block | None

**Parameters**
**seq** (SequenceNode)

angr.analyses.decompiler.utils.**first_nonlabel_nonphi_node**(*seq*)

**Return type**
*BaseNode* | Block | None

**Parameters**
**seq** (SequenceNode)

angr.analyses.decompiler.utils.**remove_labels**(*graph*)

**Parameters**
**graph** (*DiGraph*)

angr.analyses.decompiler.utils.**add_labels**(*graph*, *ail_manager*)

**Parameters**

- **graph** (*DiGraph*)
- **ail_manager** (*Manager*)

angr.analyses.decompiler.utils.**update_labels**(*graph*, *ail_manager*)

A utility function to recreate the labels for every node in an AIL graph. This useful when you are working with a graph where only _some_ of the nodes have labels.

**Parameters**

- **graph** (*DiGraph*)
- **ail_manager** (*Manager*)

angr.analyses.decompiler.utils.**structured_node_has_multi_predecessors**(*node*, *graph*)

**Return type**
bool

**Parameters**

- **node** (SequenceNode | MultiNode | *Block*)
- **graph** (*DiGraph*)

angr.analyses.decompiler.utils.**structured_node_is_simple_return**(*node*, *graph*, *use_packed_successors=False*)

Check if a "simple return" is contained within the node. A simple return looks like this:

```
if (cond) {
  // simple return
  ...
  return 0;
}
...
```

Returns true on any block ending in linear statements and a return.

**Return type**
bool

**Parameters**

- **node** (SequenceNode | MultiNode)
- **graph** (*DiGraph*)

angr.analyses.decompiler.utils.**structured_node_is_simple_return_strict**(*node*)

Returns True iff the node exclusively contains a return statement.

**Return type**
bool

**Parameters**
**node** (BaseNode | SequenceNode | MultiNode | *Block*)

angr.analyses.decompiler.utils.**is_statement_terminating**(*stmt*, *functions*)

**Return type**
bool

**Parameters**
**stmt** (Statement)

angr.analyses.decompiler.utils.**peephole_optimize_exprs**(*block*, *expr_opts*, *walker=None*, *graph_defs=None*)

**Parameters**
**graph_defs** (GraphVVarDefs | *None*)

angr.analyses.decompiler.utils.**peephole_optimize_expr**(*expr*, *expr_opts*)

**Parameters**

- **expr** (Expression)
- **expr_opts** (*list*[PeepholeOptimizationExprBase])

angr.analyses.decompiler.utils.**copy_graph**(*graph*)

Copy AIL Graph.

**Return type**
networkx.DiGraph[Block]

**Returns**
A copy of the AIl graph.

**Parameters**
**graph** (*networkx.DiGraph[Block]*)

angr.analyses.decompiler.utils.**build_stmt_opts_by_kind**(*stmt_opts*)

Index statement-peephole optimizers by `kind` string.

angr.analyses.decompiler.utils.**peephole_optimize_stmts**(*block*, *stmt_opts*, *, *stmt_opts_by_kind=None*, *fixpoint_exprs=None*)

**Parameters**
**fixpoint_exprs** – IDs of the statements the preceding expression pass left untouched *and* whose expression optimizers all reported `fixpoint_reached`.

angr.analyses.decompiler.utils.**match_stmt_classes**(*all_stmts*, *idx*, *stmt_class_seq*)

**Return type**
bool

**Parameters**

- **all_stmts** (*list*)
- **idx** (*int*)
- **stmt_class_seq** (*Iterable[type]*)

angr.analyses.decompiler.utils.**peephole_optimize_multistmts**(*block*, *stmt_opts*)

**Parameters**
**stmt_opts** (*list[PeepholeOptimizationMultiStmtBase]*)

angr.analyses.decompiler.utils.**decompile_functions**(*path*, *functions=None*, *structurer=None*, *catch_errors=False*, *show_casts=True*, *base_address=None*, *preset=None*, *cca=False*, *cca_callsites=True*, *llm=False*, *progressbar=False*, *postmortem=False*)

Decompile a binary into a set of functions.

**Parameters**

- **path** – The path to the binary to decompile.
- **functions** (list[int | str] | None) – The functions to decompile. If None, all functions will be decompiled.
- **structurer** (str | None) – The structuring algorithms to use.
- **catch_errors** (bool) – The structuring algorithms to use.
- **show_casts** (bool) – Whether to show casts in the decompiled output.
- **base_address** (int | None) – The base address of the binary.
- **preset** (str | None) – The configuration preset to use during decompilation.

- **cca** (*bool*)
- **cca_callsites** (*bool*)
- **llm** (*bool*)
- **progressbar** (*bool*)
- **postmortem** (*bool*)

**Return type**
str

**Returns**
The decompilation of all functions appended in order.

angr.analyses.decompiler.utils.**calls_in_graph**(*graph*, *consider_conditions=False*)

Counts the number of calls in a graph full of AIL Blocks

**Return type**
int

**Parameters**

- **graph** (*DiGraph*)
- **consider_conditions** (*bool*)

angr.analyses.decompiler.utils.**call_exprs_in_graph**(*graph*, *consider_conditions=False*)

Return a list of all call expressions in a given AIL graph.

**Return type**
list[tuple[tuple[, int], *Call*]]

**Parameters**

- **graph** (*DiGraph*)
- **consider_conditions** (*bool*)

angr.analyses.decompiler.utils.**has_addr_dups**(*graph*)

**Return type**
bool

**Parameters**
**graph** (*networkx.DiGraph[Block]*)

angr.analyses.decompiler.utils.**find_block_by_addr**(*graph*, *addr*, *insn_addr=False*)

**Return type**
Block

**Parameters**
**graph** (*DiGraph*)

angr.analyses.decompiler.utils.**find_block_by_addr_and_idx**(*graph*, *addr*, *idx*)

**Return type**
Block

**Parameters**

- **graph** (*DiGraph*)
- **addr** (*int*)

- **idx** (*int | None*)

angr.analyses.decompiler.utils.**sequence_to_blocks**(*seq*)

Converts a sequence node (BaseNode) to a list of ailment blocks contained in it and all its children.

**Return type**
list[Block]

**Parameters**
**seq** (BaseNode)

angr.analyses.decompiler.utils.**sequence_to_statements**(*seq*, *exclude=(<class 'angr.ailment.statement.Jump'>, <class 'angr.ailment.statement.Jump'>)*)

Converts a sequence node (BaseNode) to a list of ailment Statements contained in it and all its children. May exclude certain types of statements.

**Return type**
list[*Statement*]

**Parameters**
**seq** (BaseNode)

angr.analyses.decompiler.utils.**remove_edges_in_ailgraph**(*ail_graph*, *edges_to_remove*)

**Return type**
None

**Parameters**

- **ail_graph** (*DiGraph*)
- **edges_to_remove** (*list[tuple[tuple[int, int], tuple[int, int]]]*)

### angr.analyses.decompiler.variable_map

angr.analyses.decompiler.variable_map.**variable_map_of**(*manager*)

Return the *VariableMap* attached to an ailment `Manager`, lazily creating and attaching an empty one if the manager does not have a map yet (e.g. Managers constructed outside of Clinic in tests). This keeps consumers that reach the map through `manager.variable_map` from having to special-case `None`.

**Return type**
*VariableMap*

**Parameters**
**manager** (*Manager*)

**class** angr.analyses.decompiler.variable_map.**VariableMap**

Bases: object

A side container that maps the `.idx` of AIL `Statement` and `Expression` objects to variable-related information.

The following pieces of information are tracked:

- `variable` (a `SimVariable`) and `variable_offset` (an `int`): the variable that an AIL atom resolves to, and the offset into that variable.
- `custom_string` (a `bool`): whether a `Const` expression refers to a custom string.
- `reference_values` (a `dict` mapping `SimType` to a value): reference values associated with a `Const` expression (e.g., custom strings).

- `reference_variable` (a `SimVariable`) and `reference_variable_offset` (an `int`): the variable that a constant expression references, and the offset into it. These are siblings of `variable` / `variable_offset` that are specifically used for constants that reference global/extern variables.
- `prototype` (a `SimTypeFunction`) and `calling_convention` (a `SimCC`): the call-site prototype and calling convention associated with an AIL `Call` expression. These used to live directly on the `Call` object; they are heavy, non-serializable Python references, so they are tracked here instead.
- `variant` (an `EnumVariant`): the enum variant that a Rust `Let` expression binds.
- `returnty` (a `SimType`): the return type of a Rust `FunctionLikeMacro` call.

Keys are the integer `.idx` values of AIL Statement/Expression objects. Because `Clinic` builds one `ailment.Manager` per invocation, `.idx` values are unique within a single Clinic. So a VariableMap is scoped to one Clinic instance and is stored in the corresponding `DecompilationCache`.

**__init__**()

**variable**(*obj*)

**Return type**
*SimVariable* | None

**Parameters**
**obj** (*AILObject | int*)

**variable_offset**(*obj*)

**Return type**
int

**Parameters**
**obj** (*AILObject | int*)

**custom_string**(*obj*)

**Return type**
bool

**Parameters**
**obj** (*AILObject | int*)

**reference_values**(*obj*)

**Return type**
dict[*SimType*, Any] | None

**Parameters**
**obj** (*AILObject | int*)

**reference_variable**(*obj*)

**Return type**
*SimVariable* | None

**Parameters**
**obj** (*AILObject | int*)

**reference_variable_offset**(*obj*)

**Return type**
int

**Parameters**
**obj** (*AILObject | int*)

**has_variable**(*obj*)

**Return type**
bool

**Parameters**
**obj** (*AILObject | int*)

**prototype**(*obj*)

**Return type**
*SimTypeFunction* | None

**Parameters**
**obj** (*AILObject | int*)

**calling_convention**(*obj*)

**Return type**
*SimCC* | None

**Parameters**
**obj** (*AILObject | int*)

**variant**(*obj*)

**Return type**
Any

**Parameters**
**obj** (*AILObject | int*)

**returnty**(*obj*)

**Return type**
*SimType* | None

**Parameters**
**obj** (*AILObject | int*)

**set_variable**(*obj*, *variable*, *offset=0*)

Set the variable information for an AIL atom. If `variable` is `None`, the variable information for this atom is cleared.

**Return type**
None

**Parameters**

- **obj** (*AILObject | int*)
- **variable** (SimVariable | *None*)
- **offset** (*int*)

**set_variable_offset**(*obj*, *offset*)

**Return type**
None

**Parameters**

- **obj** (*AILObject | int*)
- **offset** (*int*)

**set_custom_string**(*obj*, *value=True*)

**Return type**
None

**Parameters**

- **obj** (*AILObject | int*)
- **value** (*bool*)

**set_reference_values**(*obj*, *reference_values*)

**Return type**
None

**Parameters**

- **obj** (*AILObject | int*)
- **reference_values** (*dict[SimType, Any]*)

**set_reference_variable**(*obj*, *variable*, *offset=0*)

Set the reference variable information for an AIL atom. If `variable` is `None`, the reference variable information for this atom is cleared.

**Return type**
None

**Parameters**

- **obj** (*AILObject | int*)
- **variable** (*SimVariable | None*)
- **offset** (*int*)

**set_prototype**(*obj*, *prototype*)

Set the call-site prototype for an AIL Call. If `prototype` is `None`, the prototype information for this atom is cleared.

**Return type**
None

**Parameters**

- **obj** (*AILObject | int*)
- **prototype** (*SimTypeFunction | None*)

**set_calling_convention**(*obj*, *cc*)

Set the calling convention for an AIL Call. If `cc` is `None`, the calling-convention information for this atom is cleared.

**Return type**
None

**Parameters**

- **obj** (*AILObject | int*)
- **cc** (*SimCC | None*)

**set_variant**(*obj*, *variant*)

Set the enum variant for a Rust `Let` expression. If `variant` is `None`, the variant information for this atom is cleared.

**Return type**
None

**Parameters**

- **obj** (*AILObject | int*)
- **variant** (*Any*)

**set_returnty**(*obj*, *returnty*)

Set the return type for a Rust `FunctionLikeMacro` call. If `returnty` is `None`, the return-type information for this atom is cleared.

**Return type**
None

**Parameters**

- **obj** (*AILObject | int*)
- **returnty** (SimType | *None*)

**transfer**(*src*, *dst*)

Copy all variable information associated with `src` to `dst`. Used when an AIL atom is deep-copied to a new `.idx` (e.g. during structuring/duplication) so that the new atom keeps the same variable association.

**Return type**
None

**Parameters**

- **src** (TaggedObject | *int*)
- **dst** (TaggedObject | *int*)

**to_json**()

Serialize this VariableMap to a JSON-compatible object.

Variables are referenced by their `.ident` (reference-by-ident); they must be resolved back to `SimVariable` objects via a resolver in *from_json()*.

**Return type**
dict[str, Any]

**classmethod from_json**(*data*, *resolve_variable*)

Deserialize a VariableMap from a JSON-compatible object produced by *to_json()*.

**Parameters**

- **data** (dict[str, Any]) – The JSON object.
- **resolve_variable** (Callable[[str], *SimVariable* | None]) – A callable that maps a variable ident (`str`) to a `SimVariable` (or `None` if it cannot be resolved).

**Return type**
*VariableMap*

### angr.analyses.decompiler.x87_fsw

Evaluation of integer expressions derived from an x87 `CmpF` result or an `fxam` classification.

`CmpF` yields one of four codes (GT 0x00, LT 0x01, EQ 0x40, unordered 0x45). `fnstsw ax` places them in AH together with the (unknown) top-of-stack pointer; `test ah, imm` / `sahf` / `and ah, 0x45; cmp ah, 0x40` then test individual bits. Instead of matching every such shape structurally, we evaluate the expression in a known-bits domain once per outcome; the `ftop` contribution and the preserved OF bit of `sahf` drop out as unknown bits that the final mask discards. The resulting outcome -> value table is then turned into an IEEE comparison.

`__fxam(x)` is handled the same way over its outcomes: the C3/C2/C0 class bits (Intel SDM, FXAM) times the C1 sign. `x87_fprem[1]_c3210(a, b)` has every C3/C2/C1/C0 combination as an outcome (C2: the remainder is partial). A boolean placed at the C2 position (`cond * 0x400`, how fsin/fcos/fptan report an out-of-range operand) has two outcomes.

**class** angr.analyses.decompiler.x87_fsw.**FswTable**

Bases: `object`

Values of one or more integer expressions for each outcome of the single CmpF or __fxam they are built from.

`values[outcome]` holds one integer per evaluated expression.

**__init__**(*source*, *operands*, *values*)

**Parameters**

- **source** (*str*)
- **operands** (*tuple[Expression, ...]*)
- **values** (*dict[int, tuple[int, ...]]*)

**source**

**operands**

**values**

**true_set**(*pred*)

**Return type**
frozenset[int]

**Parameters**
**pred** (*Callable[[tuple[int, ...]], bool]*)

angr.analyses.decompiler.x87_fsw.**evaluate_over_fsw**(*exprs*, *vvar_defs=None*, *load_resolver=None*, *tmp_defs=None*, *fp_compare_leaves=False*)

Evaluate integer expressions that depend on a single CmpF(a, b), __fxam(x), x87_fprem[1]_c3210(a, b) or C2 boolean for each of its outcomes.

**Parameters**

- **load_resolver** (Callable[[*Load*], *Expression* | None] | None) – Maps a Load to the expression it reads (e.g., a status word stored earlier), or None.
- **fp_compare_leaves** (bool) – Also treat float comparisons and NaN tests of the CmpF operands as functions of the outcome.
- **exprs** (*Sequence[Expression]*)
- **vvar_defs** (*Mapping[int, Expression] | None*)
- **tmp_defs** (*dict[int, Expression] | None*)

**Return type**
*FswTable* | None

**Returns**
The table of values, or None if no source is found or any expression has unknown bits for some outcome.

angr.analyses.decompiler.x87_fsw.**fsw_predicate**(*table*, *true_set*, *idx*, *ail_manager*, *bits*, *tags*)

Convert *true_set* to a corresponding AIL expression. Returns None if no such expression exists.

**Return type**
*Expression* | None

**Parameters**

- **table** (*FswTable*)
- **true_set** (*frozenset[int]*)
- **idx** (*int | None*)
- **ail_manager** (*Manager*)
- **bits** (*int*)
- **tags** (*TagsView | dict[str, Any]*)

angr.analyses.decompiler.x87_fsw.**fxam_predicate**(*true_set*, *x*, *idx*, *ail_manager*, *bits*, *tags*)

Build the classification test of `x` that is exactly true for the fxam outcomes in `true_set`. This includes isnan, isinf, isfinite, isnormal, x == 0, signbit, and the negation of each one of them.

**Return type**
*Expression* | None

**Parameters**

- **true_set** (*frozenset[int]*)
- **x** (*Expression*)
- **idx** (*int | None*)
- **ail_manager** (*Manager*)
- **bits** (*int*)
- **tags** (*TagsView | dict[str, Any]*)

angr.analyses.decompiler.x87_fsw.**fp_predicate_from_outcomes**(*true_set*, *operands*, *idx*, *ail_manager*, *bits*, *tags*)

Build the comparison for the CmpF outcomes in `true_set`.

Printed FP comparisons are ordered source-level predicates, as IDA prints them: the unordered outcome is folded into the comparison (`{LT, UN}` is `a < b`, `{GT, EQ, UN}` is `a >= b`) since it only reflects the parity check the compiler emits next to the comparison. `{UN}` and its complement are NaN tests and stay exact.

**Return type**
*Expression*

**Parameters**

- **true_set** (*frozenset[int]*)
- **operands** (*tuple[Expression, Expression]*)
- **idx** (*int | None*)

- **ail_manager** (*Manager*)
- **bits** (*int*)
- **tags** (*TagsView | dict[str, Any]*)

angr.analyses.decompiler.x87_fsw.**fold_fp_logic**(*expr*, *ail_manager*, *vvar_defs=None*, *tmp_defs=None*)

Rebuild a boolean combination of comparisons and NaN tests of one operand pair, e.g. `a != b ? 1 : isunordered(a, b)`, `a == b && !isunordered(a, b)` or `!(a < b || isunordered(a, b))`, as the single ordered comparison (see fp_predicate_from_outcomes).

**Return type**
*Expression* | None

**Returns**
The comparison, or None if expr is not such a combination or is a NaN test by itself.

**Parameters**

- **expr** (Expression)
- **ail_manager** (*Manager*)
- **vvar_defs** (*dict[int, Expression] | None*)
- **tmp_defs** (*dict[int, Expression] | None*)

angr.analyses.decompiler.x87_fsw.**lower_cmpf_value**(*expr*, *ail_manager*)

Exact C for an integer expression of one CmpF(a, b) and constants: `isunordered(a, b) ? v_un : a == b ? v_eq : a < b ? v_lt : v_gt`. A constant OR-ed on top (e.g., the ftop bits of a status word) is kept. A test whose value equals the fall-through value is dropped: later tests are false for the outcomes tested before them.

**Return type**
*Expression* | None

**Returns**
The replacement, or None if expr is not such an expression.

**Parameters**

- **expr** (Expression)
- **ail_manager** (*Manager*)

angr.analyses.decompiler.x87_fsw.**fp_operands_match**(*a*, *b*)

Whether two float comparison operands are the same value, ignoring exact FP widening (float -> double).

**Return type**
bool

**Parameters**

- **a** (Expression)
- **b** (Expression)

angr.analyses.decompiler.x87_fsw.**const_is_nan**(*const*)

**Return type**
bool

**Parameters**
**const** (Const)

angr.analyses.decompiler.x87_fsw.**store_forwarder**(*statements*, *stmt_idx*, *has_call_memo=None*)

Resolve a Load in statement `stmt_idx` to the data of an earlier Store in the same block that fully covers it, e.g. `fnstsw word [ebp-0xa0]; test byte [ebp-0x9f], 0x41`. The search stops at any statement that may write memory the Load could read.

**Return type**
Callable[[*Load*], *Expression* | None]

**Parameters**

- **statements** (*Sequence[Statement]*)
- **stmt_idx** (*int*)
- **has_call_memo** (*dict[int, bool] | None*)

### 10.3.20 angr.analyses.deobfuscator

**class** angr.analyses.deobfuscator.**APIObfType1PeepholeOptimizer**

Bases: *PeepholeOptimizationExprBase*

Integrate type-1 deobfuscated API into decompilation output.

**NAME = 'Simplify Type 1 API obfuscation references'**

**expr_classes = (<class 'angr.ailment.expression.Load'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (Load)

**class** angr.analyses.deobfuscator.**APIObfType3PeepholeOptimizer**

Bases: *PeepholeOptimizationExprBase*

Integrate type-3 deobfuscated APIs (calls with const arguments which return APIs) into the decompilation output.

**NAME = 'Simplify Type 3 API obfuscation references'**

**expr_classes = (<class 'angr.ailment.expression.Call'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (Call)

**class** angr.analyses.deobfuscator.**APIObfuscationFinder**

Bases: *Analysis*

An analysis that automatically finds API "obfuscation" routines.

Currently, we support the following API "obfuscation" styles:

- Type 1: sub_A("dll_name", "api_name") where sub_A ends up calling LoadLibrary.
- Type 2: GetProcAddress(_, "api_name").

**__init__**(*decompiler_options=None*)

**Parameters**
**decompiler_options** (list[tuple[*DecompilationOption* | str, Any]] | None) – Options for the decompilations that the hash-lookup API deobfuscator runs.

**analyze**()

**static is_libname**(*name*)

**Return type**
bool

**Parameters**
**name** (*str*)

**static is_apiname**(*name*)

**Return type**
bool

**Parameters**
**name** (*str*)

**class** angr.analyses.deobfuscator.**DataTransformationEmbedder**

Bases: *Analysis*

An analysis that finds potentially inlined static data transformation logic and embeds the transformed data in decompilation whenever possible.

Some current limitations: - We assume the data transformation logic is inlined completely within a single function.

**__init__**(*func*, *clinic*, *cfunc*, *outlining_max_args=1*, *preset='malware'*)

**Parameters**

- **func** (Function)
- **clinic** (Clinic)
- **cfunc** (CFunction | *None*)
- **outlining_max_args** (*int*)
- **preset** (*str*)

**class** angr.analyses.deobfuscator.**HashLookupAPIDeobfuscator**

Bases: *Analysis*

An analysis that finds functions accessing loader metadata which take concrete arguments and executes them to see if they resolve symbols.

**__init__**(*lifter*, *func_addrs=None*)

**Parameters**

- **lifter** (*Callable[[*Function*], *Clinic | *None*]*)
- **func_addrs** (*Sequence[int] | None*)

**class** angr.analyses.deobfuscator.**StringObfType1PeepholeOptimizer**

Bases: *PeepholeOptimizationExprBase*

Integrate type-1 deobfuscated strings into decompilation output.

**NAME = 'Simplify Type 1/2 string deobfuscation references'**

**expr_classes = (<class 'angr.ailment.expression.Call'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (Call)

class angr.analyses.deobfuscator.**StringObfType3Rewriter**

Bases: *OptimizationPass*

Type-3 optimization pass replaces deobfuscate_string calls with the deobfuscated strings, and then removes arguments on the stack.

**ARCHES = ['X86', 'AMD64']**

**PLATFORMS = ['windows']**

**STAGE: *OptimizationPassStage* = 5**

**NAME = 'Simplify Type 3 string deobfuscation calls'**

**DESCRIPTION = 'Simplify Type 3 string deobfuscation calls'**

**stmt_classes = ()**

**__init__**(**args*, ***kwargs*)

**static is_call_or_call_assignment**(*stmt*)

**Return type**
bool

class angr.analyses.deobfuscator.**StringObfuscationFinder**

Bases: *Analysis*

An analysis that automatically finds string obfuscation routines.

**__init__**(*functions=None*)

**Parameters**
**functions** (*list[Function] | None*)

**analyze**()

### angr.analyses.deobfuscator.api_obf_finder

class angr.analyses.deobfuscator.api_obf_finder.**APIObfuscationType**

Bases: IntEnum

**TYPE_1 = 0**

**__new__**(*value*)

class angr.analyses.deobfuscator.api_obf_finder.**APIDeobFuncDescriptor**

Bases: object

**__init__**(*type_*, *, *func_addr*, *libname_argidx*, *funcname_argidx*)

**Parameters**

- **type_** (APIObfuscationType)
- **func_addr** (*int*)
- **libname_argidx** (*int*)
- **funcname_argidx** (*int*)

class angr.analyses.deobfuscator.api_obf_finder.**Type1AssignmentFinder**

Bases: *CStructuredCodeWalker*

**__init__**(*func_addr*, *desc*)

**Parameters**

- **func_addr** (*int*)
- **desc** (APIDeobFuncDescriptor)

**assignments: dict[int, tuple[str, str]]**

**handle_CAssignment**(*obj*)

**Parameters**
**obj** (CAssignment)

class angr.analyses.deobfuscator.api_obf_finder.**APIObfuscationFinder**

Bases: *Analysis*

An analysis that automatically finds API "obfuscation" routines.

Currently, we support the following API "obfuscation" styles:

- Type 1: sub_A("dll_name", "api_name") where sub_A ends up calling LoadLibrary.
- Type 2: GetProcAddress(_, "api_name").

**__init__**(*decompiler_options=None*)

**Parameters**
**decompiler_options** (list[tuple[*DecompilationOption* | str, Any]] | None) – Options for the decompilations that the hash-lookup API deobfuscator runs.

**analyze**()

**static is_libname**(*name*)

**Return type**
bool

**Parameters**
**name** (*str*)

**static is_apiname**(*name*)

**Return type**
bool

**Parameters**
**name** (*str*)

### angr.analyses.deobfuscator.api_obf_peephole_optimizer

**class** angr.analyses.deobfuscator.api_obf_peephole_optimizer.**APIObfType1PeepholeOptimizer**

Bases: *PeepholeOptimizationExprBase*

Integrate type-1 deobfuscated API into decompilation output.

**NAME = 'Simplify Type 1 API obfuscation references'**

**expr_classes = (<class 'angr.ailment.expression.Load'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (Load)

**class** angr.analyses.deobfuscator.api_obf_peephole_optimizer.**APIObfType3PeepholeOptimizer**

Bases: *PeepholeOptimizationExprBase*

Integrate type-3 deobfuscated APIs (calls with const arguments which return APIs) into the decompilation output.

**NAME = 'Simplify Type 3 API obfuscation references'**

**expr_classes = (<class 'angr.ailment.expression.Call'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (Call)

### angr.analyses.deobfuscator.api_obf_type2_finder

**class** angr.analyses.deobfuscator.api_obf_type2_finder.**APIObfuscationType2**

Bases: object

API Obfuscation Type 2 result.

**resolved_func_name: str**

**resolved_func_ptr: *MemoryLocation***

**resolved_in: *Function***

**resolved_by: *Function***

__init__(*resolved_func_name*, *resolved_func_ptr*, *resolved_in*, *resolved_by*)

**Parameters**

- **resolved_func_name** (*str*)
- **resolved_func_ptr** (MemoryLocation)
- **resolved_in** (Function)
- **resolved_by** (Function)

**Return type**
None

class angr.analyses.deobfuscator.api_obf_type2_finder.**APIObfuscationType2Finder**

Bases: object

Finds global function pointers initialized by calls to dlsym/GetProcAddress and names them accordingly.

__init__(*project*, *kb=None*)

**Parameters**

- **project** (Project)
- **kb** (KnowledgeBase | *None*)

**results:** list[*APIObfuscationType2*]

**analyze**()

**Return type**
list[*APIObfuscationType2*]

### angr.analyses.deobfuscator.data_transformation_embedder

class angr.analyses.deobfuscator.data_transformation_embedder.**DataTransformationEmbedder**

Bases: *Analysis*

An analysis that finds potentially inlined static data transformation logic and embeds the transformed data in decompilation whenever possible.

Some current limitations: - We assume the data transformation logic is inlined completely within a single function.

__init__(*func*, *clinic*, *cfunc*, *outlining_max_args=1*, *preset='malware'*)

**Parameters**

- **func** (Function)
- **clinic** (Clinic)
- **cfunc** (CFunction | *None*)
- **outlining_max_args** (*int*)
- **preset** (*str*)

### angr.analyses.deobfuscator.hash_lookup_api_deobfuscator

class angr.analyses.deobfuscator.hash_lookup_api_deobfuscator.**HashLookupAPIDeobfuscator**

Bases: *Analysis*

An analysis that finds functions accessing loader metadata which take concrete arguments and executes them to see if they resolve symbols.

**__init__**(*lifter*, *func_addrs=None*)

**Parameters**

- **lifter** (*Callable[[Function], Clinic | None]*)
- **func_addrs** (*Sequence[int] | None*)

class angr.analyses.deobfuscator.hash_lookup_api_deobfuscator.**FindCallsTo**

Bases: *AILBlockViewer*

Walker which stores calls with a given target.

**__init__**(**args*, *target*, *variable_map=None*, ***kwargs*)

**Parameters**

**target** (*str | int*)

### angr.analyses.deobfuscator.irsb_reg_collector

class angr.analyses.deobfuscator.irsb_reg_collector.**IRSBRegisterCollector**

Bases: *SimEngineNostmtVEX*[None, None, None]

Scan the VEX IRSB to collect all registers that are read.

**__init__**(**args*, ***kwargs*)

### angr.analyses.deobfuscator.scope_ops_analyzer

class angr.analyses.deobfuscator.scope_ops_analyzer.**ScopeOpsWalker**

Bases: *CStructuredCodeWalker*

ScopeOpsWalker walks a C construct (typically a C function) and extracts counts of all operations in each scope. Its intended use is to reason about the intent of different parts of functions (e.g., crypto implementations).

**__init__**()

**handle**(*obj*)

**handle_CBinaryOp**(*obj*)

**handle_CUnaryOp**(*obj*)

class angr.analyses.deobfuscator.scope_ops_analyzer.**ScopeOpsAnalyzer**

Bases: *Analysis*

An analysis that extracts and analyzes operations used by different scopes of a function.

**__init__**(*cfunc*)

**Parameters**

**cfunc** (*CFunction*)

**filter_scopes**(*wanted_ops*, *min_count*)

**Parameters**
**wanted_ops** (*set*)

**crypto_scopes**(*min_count=20*)

### angr.analyses.deobfuscator.string_obf_finder

**class** angr.analyses.deobfuscator.string_obf_finder.**StringDeobFuncDescriptor**

Bases: object

Describes a string deobfuscation function.

**string_input_arg_idx: int**

**string_output_arg_idx: int**

**__init__**()

**string_length_arg_idx: int | None**

**string_null_terminating: bool | None**

**class** angr.analyses.deobfuscator.string_obf_finder.**StringObfuscationFinder**

Bases: *Analysis*

An analysis that automatically finds string obfuscation routines.

**__init__**(*functions=None*)

**Parameters**
**functions** (*list[Function] | None*)

**analyze**()

### angr.analyses.deobfuscator.string_obf_opt_passes

**class** angr.analyses.deobfuscator.string_obf_opt_passes.**StringObfType3Rewriter**

Bases: *OptimizationPass*

Type-3 optimization pass replaces deobfuscate_string calls with the deobfuscated strings, and then removes arguments on the stack.

**ARCHES = ['X86', 'AMD64']**

**PLATFORMS = ['windows']**

**STAGE: *OptimizationPassStage* = 5**

**NAME = 'Simplify Type 3 string deobfuscation calls'**

**DESCRIPTION = 'Simplify Type 3 string deobfuscation calls'**

**stmt_classes = ()**

**__init__**(**args*, ***kwargs*)

**static is_call_or_call_assignment**(*stmt*)

**Return type**
bool

#### angr.analyses.deobfuscator.string_obf_peephole_optimizer

class angr.analyses.deobfuscator.string_obf_peephole_optimizer.**StringObfType1PeepholeOptimizer**

Bases: *PeepholeOptimizationExprBase*

Integrate type-1 deobfuscated strings into decompilation output.

**NAME = 'Simplify Type 1/2 string deobfuscation references'**

**expr_classes = (<class 'angr.ailment.expression.Call'>,)**

**optimize**(*expr*, ***kwargs*)

**Parameters**
**expr** (Call)

### 10.3.21 angr.analyses.disassembly

class angr.analyses.disassembly.**DisassemblyPiece**

Bases: object

**addr = None**

**ident = nan**

**render**(*formatting=None*)

**Return type**
list[str]

**getpiece**(*formatting*, *column*)

**width**(*formatting*)

**height**(*formatting*)

**static color**(*string*, *coloring*, *formatting*)

**highlight**(*string*, *formatting=None*)

class angr.analyses.disassembly.**FunctionStart**

Bases: *DisassemblyPiece*

**__init__**(*func*)

Constructor.

**Parameters**
**func** (*angr.knowledge.Function*) – The function instance.

**height**(*formatting*)

class angr.analyses.disassembly.**Label**

Bases: *DisassemblyPiece*

**__init__**(*addr*, *name*)

class angr.analyses.disassembly.**IROp**

Bases: *DisassemblyPiece*

__init__(*addr*, *seq*, *obj*, *irsb*)

**Parameters**

- **addr** (*int*)
- **seq** (*int*)
- **obj** (*IRStmt | PcodeOp*)
- **irsb** (*IRSB | IRSB*)

**addr:** int

**seq:** int

**obj:** IRStmt | PcodeOp

**irsb:** IRSB | *IRSB*

class angr.analyses.disassembly.**BlockStart**

Bases: *DisassemblyPiece*

__init__(*block*, *parentfunc*, *project*)

class angr.analyses.disassembly.**Hook**

Bases: *DisassemblyPiece*

__init__(*block*)

class angr.analyses.disassembly.**Instruction**

Bases: *DisassemblyPiece*

__init__(*insn*, *parentblock*, *project=None*)

**opcode:** *Opcode*

property **mnemonic**

**reload_format**()

**dissect_instruction**()

**dissect_instruction_for_arm**()

static **split_arm_op_string**(*op_str*)

**Parameters**

**op_str** (*str*)

**dissect_instruction_by_default**()

static **split_op_string**(*insn_str*)

class angr.analyses.disassembly.**SootExpression**

Bases: *DisassemblyPiece*

__init__(*expr*)

class angr.analyses.disassembly.**SootExpressionTarget**

Bases: *SootExpression*

__init__(*target_stmt_idx*)

class angr.analyses.disassembly.**SootExpressionStaticFieldRef**

Bases: *SootExpression*

__init__(*field*)

class angr.analyses.disassembly.**SootExpressionInvoke**

Bases: *SootExpression*

Virtual = 'virtual'

Static = 'static'

Special = 'special'

__init__(*invoke_type*, *expr*)

class angr.analyses.disassembly.**SootStatement**

Bases: *DisassemblyPiece*

__init__(*block_addr*, *raw_stmt*)

property stmt_idx

class angr.analyses.disassembly.**Opcode**

Bases: *DisassemblyPiece*

__init__(*parentinsn*)

class angr.analyses.disassembly.**Operand**

Bases: *DisassemblyPiece*

__init__(*op_num*, *children*, *parentinsn*)

children: list

property cs_operand

static build(*operand_type*, *op_num*, *children*, *parentinsn*)

class angr.analyses.disassembly.**ConstantOperand**

Bases: *Operand*

class angr.analyses.disassembly.**RegisterOperand**

Bases: *Operand*

property register

class angr.analyses.disassembly.**MemoryOperand**

Bases: *Operand*

__init__(*op_num*, *children*, *parentinsn*)

values: list[str | *DisassemblyPiece*]

class angr.analyses.disassembly.**OperandPiece**

Bases: *DisassemblyPiece*

addr = None

**parentop = None**

**ident = None**

**class** angr.analyses.disassembly.**Register**

Bases: *OperandPiece*

**__init__**(*reg*, *prefix=''*)

**class** angr.analyses.disassembly.**Value**

Bases: *OperandPiece*

**__init__**(*val*, *render_with_sign*, *render_with_pound_sign=False*)

**Parameters**
**render_with_pound_sign** (*bool*)

**property project**

**class** angr.analyses.disassembly.**Comment**

Bases: *DisassemblyPiece*

**__init__**(*addr*, *text*)

**height**(*formatting*)

**class** angr.analyses.disassembly.**FuncComment**

Bases: *DisassemblyPiece*

**__init__**(*func*)

**class** angr.analyses.disassembly.**Disassembly**

Bases: *Analysis*

Produce formatted machine code disassembly.

**__init__**(*function=None*, *ranges=None*, *thumb=False*, *include_ir=False*, *block_bytes=None*)

**Parameters**

- **function** (Function | *None*)
- **ranges** (*Sequence[tuple[int, int]]* | *None*)
- **thumb** (*bool*)
- **include_ir** (*bool*)
- **block_bytes** (bytes | *None*)

**func_lookup**(*block*)

**parse_block**(*block*)

Parse instructions for a given block node

**Return type**
None

**Parameters**
**block** (BlockNode)

**render**(*formatting=None*, *show_edges=True*, *show_addresses=True*, *show_bytes=False*, *ascii_only=None*, *color=True*, *min_edge_depth=0*)

Render the disassembly to a string, with optional edges and addresses.

Color will be added by default, if enabled. To disable color pass an empty formatting dict.

**Return type**
str

**Parameters**

- **show_edges** (*bool*)
- **show_addresses** (*bool*)
- **show_bytes** (*bool*)
- **ascii_only** (*bool | None*)
- **color** (*bool*)
- **min_edge_depth** (*int*)

### 10.3.22 angr.analyses.disassembly_utils

angr.analyses.disassembly_utils.**decode_instruction**(*arch*, *instr*)

### 10.3.23 angr.analyses.dominance_frontier

**class** angr.analyses.dominance_frontier.**DominanceFrontier**

Bases: Generic[T_co]

Computes the dominance frontier of all nodes in a function graph, and provides an easy-to-use interface for querying the frontier information.

**Overloads**

- **func** (), **func_graph** (networkx.DiGraph[T_co]), **entry** (T_co), **exception_edges** (bool) = False
- **func** (), **func_graph** (networkx.DiGraph[CodeNode] | None) = None, **entry** (*CodeNode* | None) = None, **exception_edges** (bool) = False

**__init__**(*func*, *func_graph=None*, *entry=None*, *exception_edges=False*)

**Overloads**

- **func** (), **func_graph** (networkx.DiGraph[T_co]), **entry** (T_co), **exception_edges** (bool) = False
- **func** (), **func_graph** (networkx.DiGraph[CodeNode] | None) = None, **entry** (*CodeNode* | None) = None, **exception_edges** (bool) = False

**Parameters**

- **func** (Function)
- **func_graph** (*networkx.DiGraph[T_co] | None*)

angr.analyses.dominance_frontier.**calculate_iterated_dominace_frontier_set**(*frontiers*, *blocks*)

**Return type**
set

**Parameters**

- **frontiers** (*dict*)
- **blocks** (*set*)

### 10.3.24 angr.analyses.fcp

**class** angr.analyses.fcp.**FastConstantPropagation**

Bases: *Analysis*

An extremely fast constant propagation analysis that finds function-wide constant values with potentially high false negative rates.

**__init__**(*func*, *blocks=None*, *vex_cross_insn_opt=False*, *load_callback=None*)

**Parameters**

- **func** (Function)
- **blocks** (*set[Block] | None*)
- **vex_cross_insn_opt** (*bool*)
- **load_callback** (*Callable | None*)

#### Submodules

*fcp*

#### angr.analyses.fcp.fcp

**class** angr.analyses.fcp.fcp.**SV**

Bases: object

SizedValue: A faster implementation of claripy.ast.BV.

**__init__**(*value*, *bits*)

**value**

**bits**

**class** angr.analyses.fcp.fcp.**FCPState**

Bases: object

The abstract state for FastConstantPropagation.

**__init__**()

**tmps**

**simple_stack**

**regs:** dict[int, *SV*]

**stack:** dict[int, *SV*]

**sp_value**

**bp_value**

**register_read**(*offset*, *size_in_bytes*)

**Return type**
int | None

**Parameters**
**size_in_bytes** (*int*)

**register_written**(*offset*, *size_in_bytes*, *value*)

**Parameters**

- **offset** (*int*)
- **size_in_bytes** (*int*)
- **value** (*int | None*)

**stack_read**(*offset*, *size_int_bytes*)

**Return type**
int | None

**Parameters**

- **offset** (*int*)
- **size_int_bytes** (*int*)

**stack_written**(*offset*, *size_int_bytes*, *value*)

**Parameters**

- **offset** (*int*)
- **size_int_bytes** (*int*)
- **value** (*int | None*)

**copy**(*with_tmps=False*)

**Return type**
*FCPState*

**Parameters**
**with_tmps** (*bool*)

**callee_stored_regs**

**class** angr.analyses.fcp.fcp.**SimEngineFCPVEX**

Bases: *SimEngineNostmtVEX*[*FCPState*, *SpOffset* | *RegisterOffset* | int, None], *SimEngineLight*[type[*FCPState*], *SpOffset* | *RegisterOffset* | int, *Block*, None]

THe engine for FastConstantPropagation.

**__init__**(*project*, *bp_as_gpr*, *replacements*, *load_callback=None*)

**Parameters**

- **bp_as_gpr** (*bool*)
- **replacements** (*dict[int, dict]*)
- **load_callback** (*Callable | None*)

class angr.analyses.fcp.fcp.**FastConstantPropagation**

Bases: *Analysis*

An extremely fast constant propagation analysis that finds function-wide constant values with potentially high false negative rates.

**__init__**(*func*, *blocks=None*, *vex_cross_insn_opt=False*, *load_callback=None*)

**Parameters**

- **func** (Function)
- **blocks** (*set[Block] | None*)
- **vex_cross_insn_opt** (*bool*)
- **load_callback** (*Callable | None*)

### 10.3.25 angr.analyses.find_objects_static

class angr.analyses.find_objects_static.**PossibleObject**

Bases: object

This holds the address and class name of possible class instances. The address that it holds in mapped outside the binary so it is only valid in this analysis. TO DO: map the address to its uses in the registers/memory locations in the instructions

**__init__**(*size*, *addr*, *class_name=None*)

class angr.analyses.find_objects_static.**NewFunctionHandler**

Bases: *FunctionHandler*

**This handles calls to the function new(), by recording the size parameter passed to it and also assigns a new**
address outside the mapped binary to the newly created space(possible object).

It also tracks if the function called right after new() is passed the same 'this' pointer and is a constructor, if so we mark it as an instance of the class the constructor belongs to.(only for non stripped binaries)

**handle_local_function**(*state*, *data*)

**Parameters**

- **state** (ReachingDefinitionsState)
- **data** (FunctionCallData)

class angr.analyses.find_objects_static.**StaticObjectFinder**

Bases: *Analysis*

**This analysis tries to find objects on the heap based on calls to new(), and subsequent calls to constructors with**
the 'this' pointer

**__init__**()

### 10.3.26 angr.analyses.flirt

class angr.analyses.flirt.**FlirtAnalysis**

Bases: *Analysis*

FlirtAnalysis accomplishes two purposes:

- If a FLIRT signature file is specified, it will match the given signature file against the current binary and rename recognized functions accordingly.
- If no FLIRT signature file is specified, it will use strings to determine possible libraries embedded in the current binary, and then match all possible signatures for the architecture.

**__init__**(*sig=None*, *max_mismatched_bytes=0*, *dry_run=False*, *match_named_functions=False*)

**Parameters**

- **sig** (*FlirtSignature | str | None*)
- **max_mismatched_bytes** (*int*)
- **dry_run** (*bool*)
- **match_named_functions** (*bool*)

**class** angr.analyses.flirt.**FlirtSignature**

Bases: object

This class describes a FLIRT signature without any internal data that is only available after parsing.

**__init__**(*arch*, *platform*, *sig_name*, *sig_path*, *unique_strings=None*, *compiler=None*, *compiler_version=None*, *os_name=None*, *os_version=None*)

**Parameters**

- **arch** (*str*)
- **platform** (*str*)
- **sig_name** (*str*)
- **sig_path** (*str*)
- **unique_strings** (*set[str] | None*)
- **compiler** (*str | None*)
- **compiler_version** (*str | None*)
- **os_name** (*str | None*)
- **os_version** (*str | None*)

**exception** angr.analyses.flirt.**FlirtSignatureError**

Bases: *AngrError*

Describes errors related to FLIRT signatures, especially parsing.

**class** angr.analyses.flirt.**FlirtSignatureParsed**

Bases: object

Describes a FLIRT signature file after parsing.

**__init__**(*version*, *arch*, *file_types*, *os_types*, *app_types*, *features*, *crc*, *ctype*, *ctypes_crc*, *nfuncs*, *pattern_size*, *libname*, *root*)

**Parameters**

- **version** (*int*)
- **arch** (*int*)
- **file_types** (*int*)

- **os_types** (*int*)
- **app_types** (*int*)
- **features** (*int*)
- **crc** (*int*)
- **ctype** (*int*)
- **ctypes_crc** (*int*)
- **nfuncs** (*int | None*)
- **pattern_size** (*int | None*)
- **libname** (*str*)
- **root** (FlirtNode | *None*)

**version**

**arch**

**file_types**

**os_types**

**app_types**

**features**

**crc**

**ctype**

**ctypes_crc**

**nfuncs**

**pattern_size**

**libname**

**root**

**parse_tree**(*file_obj*, *root=False*)

Parse a FLIRT function tree.

**Return type**
*FlirtNode*

**Parameters**
**root** (*bool*)

**parse_public_function**(*file_obj*, *offset*)

**Return type**
tuple[*FlirtFunction*, int, int]

**Parameters**
**offset** (*int*)

parse_referenced_functions(*file_obj*)

**Return type**
list[*FlirtFunction*]

parse_tail_bytes(*file_obj*)

**Return type**
list[tuple[int, int]]

parse_modules(*file_obj*)

**Return type**
list[*FlirtModule*]

parse_module(*file_obj*)

**Return type**
tuple[*FlirtModule*, int]

static parse_variant_mask(*file_obj*, *length*)

**Return type**
int

**Parameters**
**length** (*int*)

static is_bit_set_be(*mask*, *mask_len*, *bit_offset*)

**Return type**
bool

**Parameters**

- **mask** (*int*)
- **mask_len** (*int*)
- **bit_offset** (*int*)

static parse_node(*file_obj*, *length*, *variant_mask*)

**Return type**
list[int]

**Parameters**

- **length** (*int*)
- **variant_mask** (*int*)

classmethod parse_header(*file_obj*)

Parse only the FLIRT signature header (no function tree).

The returned object has `root` set to None. Use `parse()` if you also need the function tree, or call `parse_tree_from()` later on a separately opened file to populate `root` on demand.

The following struct definitions come from radare2

// FLIRT v5+ ut8 magic[6]; ut8 version; ut8 arch; ut32 file_types; ut16 os_types; ut16 app_types; ut16 features; ut16 old_n_functions; ut16 crc16; ut8 ctype[12]; ut8 library_name_len; ut16 ctypes_crc16;

// FLIRT v6+ ut32 nfuncs;

// FLIRT v8+ ut16 pattern_size;

// FLIRT v10 ut16 unknown;

**Return type**
*FlirtSignatureParsed*

**classmethod parse**(*file_obj*)

Parse a FLIRT signature file, including the function tree.

**Return type**
*FlirtSignatureParsed*

angr.analyses.flirt.**flirt_arch_to_arch_name**(*flirt_arch*, *app_types*)

Convert FLIRT architecture ID to architecture name.

**Parameters**

- **flirt_arch** (int) – FLIRT architecture ID.
- **app_types** (int) – FLIRT application types.

**Return type**
str

**Returns**
Architecture name.

angr.analyses.flirt.**flirt_os_type_to_os_name**(*os_type*)

Convert FLIRT OS type to OS name.

**Parameters**
**os_type** (int) – FLIRT OS type.

**Return type**
str

**Returns**
OS name.

### angr.analyses.flirt.flirt

class angr.analyses.flirt.flirt.**FlirtAnalysis**

Bases: *Analysis*

FlirtAnalysis accomplishes two purposes:

- If a FLIRT signature file is specified, it will match the given signature file against the current binary and rename recognized functions accordingly.
- If no FLIRT signature file is specified, it will use strings to determine possible libraries embedded in the current binary, and then match all possible signatures for the architecture.

__init__(*sig=None*, *max_mismatched_bytes=0*, *dry_run=False*, *match_named_functions=False*)

**Parameters**

- **sig** (FlirtSignature | *str* | *None*)
- **max_mismatched_bytes** (*int*)
- **dry_run** (*bool*)
- **match_named_functions** (*bool*)

### angr.analyses.flirt.flirt_function

class angr.analyses.flirt.flirt_function.**FlirtFunction**

Bases: object

Describes a function object in a FLIRT signature.

__init__(*name*, *offset*, *local*, *collision*)

**Parameters**

- **name** (*str*)
- **offset** (*int*)
- **local** (*bool*)
- **collision** (*bool*)

**name**

**offset**

**local**

**collision**

### angr.analyses.flirt.flirt_matcher

angr.analyses.flirt.flirt_matcher.**crc16**(*data*)

**Return type**
int

**Parameters**
**data** (bytes)

**class** angr.analyses.flirt.flirt_matcher.**FlirtMatcher**

Bases: object

A class that matches functions in a binary using FLIRT signatures.

**__init__**(*sig*, *func*, *get_callee_name*, *func_matched*, *mismatch_bytes_tolerance=0*)

**Parameters**

- **sig** (FlirtSignatureParsed)
- **func** (Function)
- **get_callee_name** (Callable[[Function, int, int, str], str | None])
- **func_matched** (Callable[[Function, int, FlirtFunction], None])
- **mismatch_bytes_tolerance** (int)

**match_function**(*buff*, *addr*)

**Return type**
bool

**Parameters**

- **buff** (bytes)
- **addr** (int)

### angr.analyses.flirt.flirt_module

**class** angr.analyses.flirt.flirt_module.**FlirtModule**

Bases: object

Describes a module in a FLIRT signature.

**__init__**(*length*, *crc_len*, *crc*, *pub_funcs*, *ref_funcs*, *tail_bytes*)

**Parameters**

- **length** (int)
- **crc_len** (int)
- **crc** (int)
- **pub_funcs** (list[FlirtFunction])
- **ref_funcs** (list[FlirtFunction])
- **tail_bytes** (list[tuple[int, int]])

**length**

**crc_len**

**crc**

**pub_funcs**

**ref_funcs**

**tail_bytes**

### angr.analyses.flirt.flirt_node

**class** angr.analyses.flirt.flirt_node.**FlirtNode**

Bases: object

Describes a tree node in the FLIRT signature tree.

**__init__**(*children*, *modules*, *length*, *pattern*)

**Parameters**

- **children** (*list[FlirtNode]*)
- **modules** (*list[FlirtModule]*)

### angr.analyses.flirt.flirt_sig

**exception** angr.analyses.flirt.flirt_sig.**FlirtSignatureError**

Bases: *AngrError*

Describes errors related to FLIRT signatures, especially parsing.

**class** angr.analyses.flirt.flirt_sig.**FlirtSignature**

Bases: object

This class describes a FLIRT signature without any internal data that is only available after parsing.

**__init__**(*arch*, *platform*, *sig_name*, *sig_path*, *unique_strings=None*, *compiler=None*, *compiler_version=None*, *os_name=None*, *os_version=None*)

**Parameters**

- **arch** (*str*)
- **platform** (*str*)
- **sig_name** (*str*)
- **sig_path** (*str*)
- **unique_strings** (*set[str] | None*)

- **compiler** (*str | None*)
- **compiler_version** (*str | None*)
- **os_name** (*str | None*)
- **os_version** (*str | None*)

class angr.analyses.flirt.flirt_sig.**FlirtSignatureParsed**

Bases: object

Describes a FLIRT signature file after parsing.

**__init__**(*version*, *arch*, *file_types*, *os_types*, *app_types*, *features*, *crc*, *ctype*, *ctypes_crc*, *nfuncs*, *pattern_size*, *libname*, *root*)

**Parameters**

- **version** (*int*)
- **arch** (*int*)
- **file_types** (*int*)
- **os_types** (*int*)
- **app_types** (*int*)
- **features** (*int*)
- **crc** (*int*)
- **ctype** (*int*)
- **ctypes_crc** (*int*)
- **nfuncs** (*int | None*)
- **pattern_size** (*int | None*)
- **libname** (*str*)
- **root** (FlirtNode | *None*)

**version**

**arch**

**file_types**

**os_types**

**app_types**

**features**

**crc**

**ctype**

**ctypes_crc**

**nfuncs**

**pattern_size**

**libname**

**root**

**parse_tree**(*file_obj*, *root=False*)

Parse a FLIRT function tree.

**Return type**
*FlirtNode*

**Parameters**
**root** (*bool*)

**parse_public_function**(*file_obj*, *offset*)

**Return type**
tuple[*FlirtFunction*, int, int]

**Parameters**
**offset** (*int*)

**parse_referenced_functions**(*file_obj*)

**Return type**
list[*FlirtFunction*]

**parse_tail_bytes**(*file_obj*)

**Return type**
list[tuple[int, int]]

**parse_modules**(*file_obj*)

**Return type**
list[*FlirtModule*]

**parse_module**(*file_obj*)

**Return type**
tuple[*FlirtModule*, int]

**static parse_variant_mask**(*file_obj*, *length*)

**Return type**
int

**Parameters**
**length** (*int*)

**static is_bit_set_be**(*mask*, *mask_len*, *bit_offset*)

**Return type**
bool

**Parameters**

- **mask** (*int*)
- **mask_len** (*int*)
- **bit_offset** (*int*)

**static parse_node**(*file_obj*, *length*, *variant_mask*)

**Return type**
list[int]

**Parameters**

- **length** (*int*)
- **variant_mask** (*int*)

**classmethod parse_header**(*file_obj*)

Parse only the FLIRT signature header (no function tree).

The returned object has `root` set to None. Use *parse()* if you also need the function tree, or call `parse_tree_from()` later on a separately opened file to populate `root` on demand.

The following struct definitions come from radare2

// FLIRT v5+ ut8 magic[6]; ut8 version; ut8 arch; ut32 file_types; ut16 os_types; ut16 app_types; ut16 features; ut16 old_n_functions; ut16 crc16; ut8 ctype[12]; ut8 library_name_len; ut16 ctypes_crc16;

// FLIRT v6+ ut32 nfuncs;

// FLIRT v8+ ut16 pattern_size;

// FLIRT v10 ut16 unknown;

**Return type**
*FlirtSignatureParsed*

**classmethod parse**(*file_obj*)

Parse a FLIRT signature file, including the function tree.

**Return type**
*FlirtSignatureParsed*

### angr.analyses.flirt.flirt_utils

angr.analyses.flirt.flirt_utils.**read_short**(*file_obj*)

**Return type**
int

angr.analyses.flirt.flirt_utils.**read_word**(*file_obj*)

**Return type**
int

angr.analyses.flirt.flirt_utils.**read_max_2_bytes**(*file_obj*)

**Return type**
int

angr.analyses.flirt.flirt_utils.**read_multiple_bytes**(*file_obj*)

**Return type**
int

### 10.3.27 angr.analyses.forward_analysis

**class** angr.analyses.forward_analysis.**CallGraphVisitor**

Bases: *GraphVisitor*

**Parameters**
**callgraph** (*networkx.DiGraph*)

**__init__**(*callgraph*)

**class** angr.analyses.forward_analysis.**ForwardAnalysis**

Bases: Generic[AnalysisState, NodeType, JobType, JobKey, SuccessorType]

This is my very first attempt to build a static forward analysis framework that can serve as the base of multiple static analyses in angr, including CFG analysis, VFG analysis, DDG, etc.

In short, ForwardAnalysis performs a forward data-flow analysis by traversing a graph, compute on abstract values, and store results in abstract states. The user can specify what graph to traverse, how a graph should be traversed, how abstract values and abstract states are defined, etc.

ForwardAnalysis has a few options to toggle, making it suitable to be the base class of several different styles of forward data-flow analysis implementations.

ForwardAnalysis supports a special mode when no graph is available for traversal (for example, when a CFG is being initialized and constructed, no other graph can be used). In that case, the graph traversal functionality is disabled, and the optimal graph traversal order is not guaranteed. The user can provide a job sorting method to sort the jobs in queue and optimize traversal order.

Feel free to discuss with me (Fish) if you have any suggestions or complaints.

**__init__**(*order_jobs=False*, *allow_merging=False*, *allow_widening=False*, *status_callback=None*, *graph_visitor=None*)

Constructor

**Parameters**

- **order_jobs** (*bool*) – If all jobs should be ordered or not.
- **allow_merging** (*bool*) – If job merging is allowed.
- **allow_widening** (*bool*) – If job widening is allowed.
- **graph_visitor** (Optional[*GraphVisitor*[NodeType]]) – A graph visitor to provide successors.
- **status_callback** (Callable[[ForwardAnalysis], *Any*] | *None*)

**Returns**
None

**property should_abort**

Should the analysis be terminated. :return: True/False

**property graph: DiGraph**

**property jobs**

**abort**()

Abort the analysis :return: None

**has_job**(*job*)

Checks whether there exists another job which has the same job key. :type job: JobType :param job: The job to check.

**Return type**
bool

**Returns**
True if there exists another job with the same key, False otherwise.

**Parameters**
**job** (*JobType*)

**downsize**()

**class** angr.analyses.forward_analysis.**FunctionGraphVisitor**

Bases: *GraphVisitor*

**Parameters**
**func** (*knowledge.Function*)

**__init__**(*func*, *graph=None*)

**resume_with_new_graph**(*graph*)

We can only reasonably reuse existing results if the node index of the already traversed nodes are the same as the ones from the new graph. Otherwise, we always restart.

**Return type**
bool

**Returns**
True if we are resuming, False if reset() is called.

**Parameters**
**graph** (*DiGraph*)

**class** angr.analyses.forward_analysis.**LoopVisitor**

Bases: *GraphVisitor*

**Parameters**
**loop** (angr.analyses.loopfinder.Loop) – The loop to visit.

**__init__**(*loop*)

**class** angr.analyses.forward_analysis.**SingleNodeGraphVisitor**

Bases: *GraphVisitor*

**Parameters**
**node** – The single node that should be in the graph.

**__init__**(*node*)

**node**

**node_returned**

### angr.analyses.forward_analysis.forward_analysis

**class** angr.analyses.forward_analysis.forward_analysis.**ForwardAnalysis**

Bases: Generic[AnalysisState, NodeType, JobType, JobKey, SuccessorType]

This is my very first attempt to build a static forward analysis framework that can serve as the base of multiple static analyses in angr, including CFG analysis, VFG analysis, DDG, etc.

In short, ForwardAnalysis performs a forward data-flow analysis by traversing a graph, compute on abstract values, and store results in abstract states. The user can specify what graph to traverse, how a graph should be traversed, how abstract values and abstract states are defined, etc.

ForwardAnalysis has a few options to toggle, making it suitable to be the base class of several different styles of forward data-flow analysis implementations.

ForwardAnalysis supports a special mode when no graph is available for traversal (for example, when a CFG is being initialized and constructed, no other graph can be used). In that case, the graph traversal functionality is disabled, and the optimal graph traversal order is not guaranteed. The user can provide a job sorting method to sort the jobs in queue and optimize traversal order.

Feel free to discuss with me (Fish) if you have any suggestions or complaints.

**__init__**(*order_jobs=False*, *allow_merging=False*, *allow_widening=False*, *status_callback=None*, *graph_visitor=None*)

Constructor

**Parameters**

- **order_jobs** (*bool*) – If all jobs should be ordered or not.
- **allow_merging** (*bool*) – If job merging is allowed.
- **allow_widening** (*bool*) – If job widening is allowed.
- **graph_visitor** (Optional[*GraphVisitor*[NodeType]]) – A graph visitor to provide successors.
- **status_callback** (Callable[[ForwardAnalysis], *Any*] | *None*)

**Returns**

None

**property should_abort**

Should the analysis be terminated. :return: True/False

**property graph: DiGraph**

**property jobs**

**abort**()

Abort the analysis :return: None

**has_job**(*job*)

Checks whether there exists another job which has the same job key. :type job: JobType :param job: The job to check.

**Return type**
bool

**Returns**
True if there exists another job with the same key, False otherwise.

**Parameters**
**job** (*JobType*)

**downsize**()

**class** angr.analyses.forward_analysis.forward_analysis.**ForwardAnalysisForDummies**

Bases: *ForwardAnalysis*[AnalysisState, NodeType, NodeType, JobKey, NodeType], Generic[AnalysisState, NodeType, JobKey]

**class** angr.analyses.forward_analysis.forward_analysis.**ForwardAnalysisForClinic**

Bases: *ForwardAnalysisForDummies*[AnalysisState, Block, tuple[int, int]], Generic[AnalysisState]

### angr.analyses.forward_analysis.job_info

**class** angr.analyses.forward_analysis.job_info.**JobInfo**

Bases: Generic[JobType, JobKey]

Stores information of each job.

**__init__**(*key*, *job*)

**Parameters**

- **key** (*JobKey*)
- **job** (*JobType*)

**property job: JobType**

Get the latest available job.

**Returns**
The latest available job.

**property merged_jobs**

**property widened_jobs**

**add_job**(*job*, *merged=False*, *widened=False*)

Appended a new job to this JobInfo node. :type job: :param job: The new job to append. :type merged: bool :param merged: Whether it is a merged job or not. :type widened: bool :param widened: Whether it is a widened job or not.

### angr.analyses.forward_analysis.visitors

**class** angr.analyses.forward_analysis.visitors.**CallGraphVisitor**

Bases: *GraphVisitor*

**Parameters**
**callgraph** (*networkx.DiGraph*)

__init__(*callgraph*)

class angr.analyses.forward_analysis.visitors.**FunctionGraphVisitor**

Bases: *GraphVisitor*

**Parameters**
**func** (*knowledge.Function*)

__init__(*func*, *graph=None*)

**resume_with_new_graph**(*graph*)

We can only reasonably reuse existing results if the node index of the already traversed nodes are the same as the ones from the new graph. Otherwise, we always restart.

**Return type**
bool

**Returns**
True if we are resuming, False if reset() is called.

**Parameters**
**graph** (*DiGraph*)

class angr.analyses.forward_analysis.visitors.**LoopVisitor**

Bases: *GraphVisitor*

**Parameters**
**loop** (angr.analyses.loopfinder.Loop) – The loop to visit.

__init__(*loop*)

class angr.analyses.forward_analysis.visitors.**SingleNodeGraphVisitor**

Bases: *GraphVisitor*

**Parameters**
**node** – The single node that should be in the graph.

__init__(*node*)

**node**

**node_returned**

### angr.analyses.forward_analysis.visitors.call_graph

class angr.analyses.forward_analysis.visitors.call_graph.**CallGraphVisitor**

Bases: *GraphVisitor*

**Parameters**
**callgraph** (*networkx.DiGraph*)

__init__(*callgraph*)

### angr.analyses.forward_analysis.visitors.function_graph

class angr.analyses.forward_analysis.visitors.function_graph.**FunctionGraphVisitor**

Bases: *GraphVisitor*

**Parameters**
**func** (*knowledge.Function*)

__init__(*func*, *graph=None*)

resume_with_new_graph(*graph*)

We can only reasonably reuse existing results if the node index of the already traversed nodes are the same as the ones from the new graph. Otherwise, we always restart.

**Return type**
bool

**Returns**
True if we are resuming, False if reset() is called.

**Parameters**
**graph** (*DiGraph*)

### angr.analyses.forward_analysis.visitors.graph

class angr.analyses.forward_analysis.visitors.graph.**GraphVisitor**

Bases: Generic[NodeType]

A graph visitor takes a node in the graph and returns its successors. Typically, it visits a control flow graph, and returns successors of a CFGNode each time. This is the base class of all graph visitors.

__init__()

successors(*node*)

Get successors of a node. The node should be in the graph.

**Parameters**
**node** (NodeType) – The node to work with.

**Returns**
A list of successors.

**Return type**
list[NodeType]

predecessors(*node*)

Get predecessors of a node. The node should be in the graph.

**Parameters**
**node** (NodeType) – The node to work with.

**Return type**
list[NodeType]

**Returns**
A list of predecessors.

**sort_nodes**(*nodes=None*)

Get a list of all nodes sorted in an optimal traversal order.

**Parameters**
**nodes** (Collection[NodeType] | None) – A collection of nodes to sort. If none, all nodes in the graph will be used to sort.

**Return type**
list[NodeType]

**Returns**
A list of sorted nodes.

**back_edges**()

Get a list of back edges. This function is optional. If not overridden, the traverser cannot achieve an optimal graph traversal order.

**Return type**
list[tuple[NodeType, NodeType]]

**Returns**
A list of back edges (source -> destination).

**nodes**()

Return an iterator of nodes following an optimal traversal order.

**Return type**
Iterator[NodeType]

**Returns**

**reset**()

Reset the internal node traversal state. Must be called prior to visiting future nodes.

**Returns**
None

**next_node**()

Get the next node to visit.

**Return type**
Optional[NodeType]

**Returns**
A node in the graph.

**all_successors**(*node*, *skip_reached_fixedpoint=False*)

Returns all successors to the specific node.

**Parameters**
**node** (NodeType) – A node in the graph.

**Returns**
A set of nodes that are all successors to the given node.

**Return type**
set[NodeType]

**revisit_successors**(*node*, *include_self=True*)

Revisit a node in the future. As a result, the successors to this node will be revisited as well.

**Parameters**
**node** (NodeType) – The node to revisit in the future.

**Return type**
None

**Returns**
None

**revisit_node**(*node*)

Revisit a node in the future. Do not include its successors immediately.

**Parameters**
**node** (NodeType) – The node to revisit in the future.

**Return type**
None

**Returns**
None

**reached_fixedpoint**(*node*)

Mark a node as reached fixed-point. This node as well as all its successors will not be visited in the future.

**Parameters**
**node** (NodeType) – The node to mark as reached fixed-point.

**Return type**
None

**Returns**
None

### angr.analyses.forward_analysis.visitors.loop

**class** angr.analyses.forward_analysis.visitors.loop.**LoopVisitor**

Bases: *GraphVisitor*

**Parameters**
**loop** (angr.analyses.loopfinder.Loop) – The loop to visit.

**__init__**(*loop*)

### angr.analyses.forward_analysis.visitors.single_node_graph

**class** angr.analyses.forward_analysis.visitors.single_node_graph.**SingleNodeGraphVisitor**

Bases: *GraphVisitor*

**Parameters**
**node** – The single node that should be in the graph.

**__init__**(*node*)

**node**

**node_returned**

### 10.3.28 angr.analyses.identifier

**class** angr.analyses.identifier.**Identifier**

Bases: *Analysis*

**__init__**(*cfg=None*, *require_predecessors=True*, *only_find=None*)

**run**(*only_find=None*)

**can_call_same_name**(*addr*, *name*)

**get_func_info**(*func*)

**static constrain_all_zero**(*before_state*, *state*, *regs*)

**identify_func**(*function*)

**check_tests**(*cfg_func*, *match_func*)

**map_callsites**()

**do_trace**(*addr_trace*, *reverse_accesses*, *func_info*)

**get_call_args**(*func*, *callsite*)

**static get_reg_name**(*arch*, *reg_offset*)

**Parameters**

- **arch** – the architecture
- **reg_offset** – Tries to find the name of a register given the offset in the registers.

**Returns**
The register name

**find_stack_vars_x86**(*func*)

**static make_initial_state**(*project*, *stack_length*)

**Returns**
an initial state with a symbolic stack and good options for rop

**static make_symbolic_state**(*project*, *reg_list*, *stack_length=80*)

converts an input state into a state with symbolic registers :return: the symbolic state

#### Submodules

*custom_callable*
*errors*
*func*
*functions*
*identify*
*runner*

### angr.analyses.identifier.custom_callable

**class** angr.analyses.identifier.custom_callable.**IdentifierCallable**

Bases: object

Callable is a representation of a function in the binary that can be interacted with like a native python function.

If you set perform_merge=True (the default), the result will be returned to you, and you can get the result state with callable.result_state.

Otherwise, you can get the resulting path group (immutable) at callable.result_path_group.

**__init__**(*project*, *addr*, *concrete_only=False*, *perform_merge=False*, *base_state=None*, *toc=None*, *cc=None*, *max_steps=None*)

**Parameters**

- **project** – The project to operate on
- **addr** – The address of the function to use
- **concrete_only** – Throw an exception if the execution splits into multiple paths
- **perform_merge** – Merge all result states into one at the end (only relevant if concrete_only=False)
- **base_state** – The state from which to do these runs
- **toc** – The address of the table of contents for ppc64
- **cc** – The SimCC to use for a calling convention

**set_base_state**(*state*)

Swap out the state you'd like to use to perform the call :type state: :param state: The state to use to perform the call

**get_base_state**(**args*)

**perform_call**(**args*, *prototype=None*)

### angr.analyses.identifier.errors

**exception** angr.analyses.identifier.errors.**IdentifierException**

Bases: *AngrAnalysisError*

**exception** angr.analyses.identifier.errors.**FunctionNotInitialized**

Bases: *AngrAnalysisError*

### angr.analyses.identifier.func

angr.analyses.identifier.func.**rand_str**(*length*, *byte_list=None*)

Generate a random string of *length* characters, drawn from *byte_list* (or all 256 characters if not provided).

**Return type**
str

angr.analyses.identifier.func.**rand_bytes**(*length*, *byte_list=None*)

Generate *length* random bytes, drawn from *byte_list* (or all 256 byte values if not provided).

**Return type**
bytes

class angr.analyses.identifier.func.**TestData**

Bases: object

**__init__**(*input_args*, *expected_output_args*, *expected_return_val*, *max_steps*, *preloaded_stdin=None*, *expected_stdout=None*)

class angr.analyses.identifier.func.**Func**

Bases: object

map_callsites()

do_trace(*addr_trace*, *reverse_accesses*, *func_info*)

get_call_args(*func*, *callsite*)

**static get_reg_name**(*arch*, *reg_offset*)

**Parameters**

- **arch** – the architecture
- **reg_offset** – Tries to find the name of a register given the offset in the registers.

**Returns**
The register name

**find_stack_vars_x86**(*func*)

**static make_initial_state**(*project*, *stack_length*)

**Returns**
an initial state with a symbolic stack and good options for rop

**static make_symbolic_state**(*project*, *reg_list*, *stack_length=80*)
converts an input state into a state with symbolic registers :return: the symbolic state

### angr.analyses.identifier.runner

**class** angr.analyses.identifier.runner.**Runner**

Bases: object

**__init__**(*project*, *cfg*)

**setup_state**(*function*, *test_data*, *initial_state=None*, *concrete_rand=False*)

**static syscall_hook**(*state*)

**static syscall_hook_concrete_rand**(*state*)

**get_out_state**(*function*, *test_data*, *initial_state=None*, *concrete_rand=False*, *custom_offs=None*)

## 10.3.29 angr.analyses.init_finder

**class** angr.analyses.init_finder.**SimEngineInitFinderVEX**

Bases: *SimEngineNostmtVEX*[None, Base | int | None, None]

The VEX engine class for InitFinder.

**__init__**(*project*, *replacements*, *overlay*, *pointers_only=False*)

**static is_concrete**(*expr*)

**Return type**
bool

**class** angr.analyses.init_finder.**InitializationFinder**

Bases: *ForwardAnalysis*, *Analysis*

Finds possible initializations for global data sections and generate an overlay to be used in other analyses later on.

### 10.3.30 angr.analyses.language_detector

**class** angr.analyses.language_detector.**LanguageDetectionConfidenceLevel**

Bases: Enum

Confidence level of language detection results.

**LOW = 'low'**

**MEDIUM = 'medium'**

**HIGH = 'high'**

**class** angr.analyses.language_detector.**LanguageDetectionResult**

Bases: object

Result of language/compiler detection on a binary.

**language: str = 'unknown'**

**compiler: str | None = None**

**compiler_version: str | None = None**

**confidence: *LanguageDetectionConfidenceLevel* = 'low'**

**evidence: list[str]**

**__init__**(*language='unknown'*, *compiler=None*, *compiler_version=None*, *confidence=LanguageDetectionConfidenceLevel.LOW*, *evidence=<factory>*)

**Parameters**

- **language** (*str*)
- **compiler** (*str | None*)
- **compiler_version** (*str | None*)
- **confidence** (LanguageDetectionConfidenceLevel)
- **evidence** (*list[str]*)

**Return type**
None

**class** angr.analyses.language_detector.**LanguageDetector**

Bases: *Analysis*

Detect the original programming language and compiler used to build a binary.

Supports detection of C (gcc, clang, msvc), Rust, Go, and Swift through multiple heuristic layers: DWARF debug info, .comment sections, symbol patterns, section names, and linked library names.

Usage:

```
result = project.analyses.LanguageDetector()
print(result.language)     # "rust"
print(result.compiler)     # "rustc"
print(result.confidence)   # "high"
print(result.evidence)     # ["symbol: __rust_alloc", ...]
```

__init__()

property language: str

property compiler: str | None

property compiler_version: str | None

property confidence: *LanguageDetectionConfidenceLevel*

property evidence: list[str]

### 10.3.31 angr.analyses.loop_analysis

class angr.analyses.loop_analysis.**LoopAnalysis**

Bases: *Analysis*

Analyze loop nodes in a structured C code representation and extract relevant information about the loop, including - Loop block addresses - Loop exits - Loop type - Loop condition - Max iterations - Fixed iterations

__init__(*cfunc*)

**Parameters**
**cfunc** (CFunction)

#### Submodules

*loop_analysis*

#### angr.analyses.loop_analysis.loop_analysis

class angr.analyses.loop_analysis.loop_analysis.**ASTNodeBase**

Bases: object

The base node for AST nodes used in loop analysis.

class angr.analyses.loop_analysis.loop_analysis.**VarNode**

Bases: *ASTNodeBase*

Represents a variable node in the AST; corresponds to a virtual variable in AIL.

__init__(*var_ident*)

**Parameters**
**var_ident** (*str*)

class angr.analyses.loop_analysis.loop_analysis.**ConstNode**

Bases: *ASTNodeBase*

Represents a constant value.

__init__(*value*)

**Parameters**
**value** (*int*)

class angr.analyses.loop_analysis.loop_analysis.**BinOpNode**

Bases: *ASTNodeBase*

Represents a binary operation between a variable and a constant.

**__init__**(*op*, *lhs*, *rhs*)

**Parameters**

- **op** (*str*)
- **lhs** (VarNode)
- **rhs** (ConstNode)

**class** angr.analyses.loop_analysis.loop_analysis.**AssignmentNode**

Bases: *ASTNodeBase*

Represents an assignment operation in the AST.

**__init__**(*lhs*, *rhs*)

**Parameters**

- **lhs** (VarNode)
- **rhs** (ASTNodeBase)

**class** angr.analyses.loop_analysis.loop_analysis.**AssignmentToASTVisitor**

Bases: *CStructuredCodeWalker*

A visitor that converts AIL assignments into AST nodes.

**handle_CAssignment**(*obj*)

**Return type**
*AssignmentNode* | None

**Parameters**
**obj** (CAssignment)

**handle_CVariable**(*obj*)

**Return type**
*VarNode* | None

**Parameters**
**obj** (CVariable)

**handle_CBinaryOp**(*obj*)

**Return type**
*BinOpNode* | None

**Parameters**
**obj** (CBinaryOp)

**handle_CConstant**(*obj*)

**Return type**
*ConstNode* | None

**Parameters**
**obj** (CConstant)

class angr.analyses.loop_analysis.loop_analysis.**LoopBodyControlStatementCollector**

Bases: *CStructuredCodeWalker*

A visitor that determines if there are control statements (break, continue, goto) within a loop body.

**__init__**()

**handle_CBreak**(*obj*)

**Parameters**
**obj** (CBreak)

**handle_CContinue**(*obj*)

**handle_CGoto**(*obj*)

**handle_CSwitchCase**(*obj*)

**handle_CForLoop**(*obj*)

**handle_CDoWhileLoop**(*obj*)

**handle_CWhileLoop**(*obj*)

class angr.analyses.loop_analysis.loop_analysis.**LoopBodyAssignmentCollector**

Bases: *CStructuredCodeWalker*

A visitor that collects assignments to specific variables within a loop body.

**__init__**(*var_idents*)

**Parameters**
**var_idents** (*set[str]*)

**handle_CAssignment**(*obj*)

**Parameters**
**obj** (CAssignment)

**handle_CIfElse**(*obj*)

**handle_CSwitchCase**(*obj*)

**handle_CForLoop**(*obj*)

**handle_CDoWhileLoop**(*obj*)

**handle_CWhileLoop**(*obj*)

class angr.analyses.loop_analysis.loop_analysis.**LoopVisitor**

Bases: *CStructuredCodeWalker*

A visitor that analyzes loop structures in CStructuredCode and collects relevant information for loops.

**__init__**()

**handle_CIfElse**(*obj*)

**handle_CStatements**(*obj*)

**Parameters**
**obj** (CStatements)

**handle_CAssignment**(*obj*)

**Parameters**
**obj** (CAssignment)

**handle_CWhileLoop**(*obj*)

**Parameters**
**obj** (CWhileLoop)

**handle_CDoWhileLoop**(*obj*)

**Parameters**
**obj** (CDoWhileLoop)

**handle_CForLoop**(*obj*)

**Parameters**
**obj** (CForLoop)

**class** angr.analyses.loop_analysis.loop_analysis.**LoopAnalysis**

Bases: *Analysis*

Analyze loop nodes in a structured C code representation and extract relevant information about the loop, including - Loop block addresses - Loop exits - Loop type - Loop condition - Max iterations - Fixed iterations

**__init__**(*cfunc*)

**Parameters**
**cfunc** (CFunction)

### 10.3.32 angr.analyses.loop_unroller

**class** angr.analyses.loop_unroller.**LoopUnroller**

Bases: *Analysis*

Unroll a loop in an AIL graph for a specified number of iterations.

**__init__**(*graph*, *loop_body*, *unroll_times*, *save_original*, *loop_body_incomplete=False*)

**Parameters**

- **graph** (*DiGraph*)
- **loop_body** (*set[tuple[int, int]]*)
- **unroll_times** (*int*)
- **save_original** (*bool*)
- **loop_body_incomplete** (*bool*)

#### Submodules

*loop_unroller*

#### angr.analyses.loop_unroller.loop_unroller

class angr.analyses.loop_unroller.loop_unroller.**LoopUnroller**

Bases: *Analysis*

Unroll a loop in an AIL graph for a specified number of iterations.

**__init__**(*graph*, *loop_body*, *unroll_times*, *save_original*, *loop_body_incomplete=False*)

**Parameters**

- **graph** (*DiGraph*)
- **loop_body** (*set[tuple[int, int]]*)
- **unroll_times** (*int*)
- **save_original** (*bool*)
- **loop_body_incomplete** (*bool*)

### 10.3.33 angr.analyses.loopfinder

class angr.analyses.loopfinder.**Loop**

Bases: object

**__init__**(*entry*, *entry_edges*, *break_edges*, *continue_edges*, *body_nodes*, *graph*, *subloops*)

class angr.analyses.loopfinder.**LoopFinder**

Bases: *Analysis*

Extracts all the loops from all the functions in a binary.

**__init__**(*functions=None*, *normalize=True*)

### 10.3.34 angr.analyses.outliner

class angr.analyses.outliner.**Outliner**

Bases: *Analysis*

Outliner takes a function and some locations and attempts to outline the blocks within these locations into a separate function.

**__init__**(*func*, *ail_graph*, *src_loc*, *func_entry_loc=None*, *frontier=None*, *vvar_id_start=48879*, *block_addr_start=2864381952*, *min_step=1*, *liveness=None*)

**Parameters**

- **ail_graph** (*networkx.DiGraph[Block]*)
- **src_loc** (*Address*)
- **func_entry_loc** (*Address | None*)
- **frontier** (*set[Address] | None*)
- **vvar_id_start** (*int*)
- **block_addr_start** (*int*)
- **min_step** (*int*)
- **liveness** (*SLivenessAnalysis | None*)

**dropped_return_values**

how many values the region defines for later use beyond the one a call can return; when nonzero, the outlined code loses them and the result is wrong

**cleanup_callee_graph**(*g*, *func*, *entry_loc=None*)

Remove all phi assignments whose all source variables are undefined in the graph, except those with a source at `entry_loc` (the callee's own entry, whose values are the callee's arguments).

**Parameters**

- **g** (*DiGraph*)
- **func** (Function)
- **entry_loc** (*Address | None*)

**get_interface**(*g*, *func*, *entry_loc=None*)

Recover the interface from a function AIL graph. A phi operand sourced from `entry_loc` is an argument.

**Return type**
list[*VirtualVariable*]

**Parameters**

- **g** (*networkx.DiGraph[Block]*)
- **func** (Function)
- **entry_loc** (*Address | None*)

## Submodules

*outliner*

### angr.analyses.outliner.outliner

**class** angr.analyses.outliner.outliner.**Outliner**

Bases: *Analysis*

Outliner takes a function and some locations and attempts to outline the blocks within these locations into a separate function.

**__init__**(*func*, *ail_graph*, *src_loc*, *func_entry_loc=None*, *frontier=None*, *vvar_id_start=48879*, *block_addr_start=2864381952*, *min_step=1*, *liveness=None*)

**Parameters**

- **ail_graph** (*networkx.DiGraph[Block]*)
- **src_loc** (*Address*)
- **func_entry_loc** (*Address | None*)
- **frontier** (*set[Address] | None*)
- **vvar_id_start** (*int*)
- **block_addr_start** (*int*)
- **min_step** (*int*)
- **liveness** (SLivenessAnalysis | *None*)

**dropped_return_values**

how many values the region defines for later use beyond the one a call can return; when nonzero, the outlined code loses them and the result is wrong

**cleanup_callee_graph**(*g*, *func*, *entry_loc=None*)

Remove all phi assignments whose all source variables are undefined in the graph, except those with a source at `entry_loc` (the callee's own entry, whose values are the callee's arguments).

**Parameters**

- **g** (*DiGraph*)
- **func** (Function)
- **entry_loc** (*Address | None*)

**get_interface**(*g*, *func*, *entry_loc=None*)

Recover the interface from a function AIL graph. A phi operand sourced from `entry_loc` is an argument.

**Return type**
list[*VirtualVariable*]

**Parameters**

- **g** (*networkx.DiGraph[Block]*)
- **func** (Function)
- **entry_loc** (*Address | None*)

### 10.3.35 angr.analyses.patchfinder

**class** angr.analyses.patchfinder.**OverlappingFunctionsAnalysis**

Bases: *Analysis*

Identify functions with interleaved blocks.

**__init__**()

**overlapping_functions:** `dict[int, list[int]]`

**class** angr.analyses.patchfinder.**FunctionAlignmentAnalysis**

Bases: *Analysis*

Determine typical function alignment

**__init__**()

**alignment:** `int | None`

**class** angr.analyses.patchfinder.**AtypicallyAlignedFunction**

Bases: `object`

AtypicallyAlignedFunction(function: 'Function', expected_alignment: 'int')

**function:** *Function*

**expected_alignment:** `int`

__init__(*function*, *expected_alignment*)

**Parameters**

- **function** (Function)
- **expected_alignment** (*int*)

**Return type**
None

class angr.analyses.patchfinder.**PatchedOutFunctionality**

Bases: object

PatchedOutFunctionality(patched_function: 'Function', patched_out_function: 'Function')

**patched_function:** *Function*

**patched_out_function:** *Function*

__init__(*patched_function*, *patched_out_function*)

**Parameters**

- **patched_function** (Function)
- **patched_out_function** (Function)

**Return type**
None

class angr.analyses.patchfinder.**PatchFinderAnalysis**

Bases: *Analysis*

Looks for binary patches using some basic heuristics: - Looking for interleaved functions - Looking for unaligned functions

__init__()

**atypical_alignments:** list[*AtypicallyAlignedFunction*]

**possibly_patched_out:** list[*PatchedOutFunctionality*]

### 10.3.36 angr.analyses.pathfinder

exception angr.analyses.pathfinder.**Unreachable**

Bases: Exception

class angr.analyses.pathfinder.**SimStateMarker**

Bases: object

SimStateMarker(addr: 'int', parent: 'SimStateMarker | None' = None, banned: 'bool' = False, misses: 'int' = 0)

**addr:** int

**parent:** *SimStateMarker* | None = None

**banned:** bool = False

**misses:** int = 0

__init__(*addr*, *parent=None*, *banned=False*, *misses=0*)

**Parameters**

- **addr** (*int*)
- **parent** (SimStateMarker | *None*)
- **banned** (*bool*)
- **misses** (*int*)

**Return type**
None

class angr.analyses.pathfinder.**SuccessorsKind**

Bases: Enum

**SAT = 1**

**UNSAT = 2**

**MISSING = 3**

class angr.analyses.pathfinder.**TestPathReport**

Bases: object

TestPathReport(path_markers: 'dict[int, SimStateMarker]', termination: 'SuccessorsKind')

**path_markers: dict[int, *SimStateMarker*]**

**termination: *SuccessorsKind***

__init__(*path_markers*, *termination*)

**Parameters**

- **path_markers** (*dict[int, SimStateMarker]*)
- **termination** (SuccessorsKind)

**Return type**
None

angr.analyses.pathfinder.**nilref**()

class angr.analyses.pathfinder.**Pathfinder**

Bases: *Analysis*

__init__(*start_state*, *goal_addr*, *cfg*, *cache_size=10000*)

**Parameters**

- **start_state** (SimState)
- **goal_addr** (*int*)
- **cfg** (CFGModel)

**goal_state: *SimState* | None**

**transition_cache: DiGraph[*SimStateMarker*]**

**base_heuristic: dict[int, int]**

**cache_state**(*state*)

**Parameters**
**state** (SimState)

**marker_to_state**(*marker*)

**Return type**
*SimState* | None

**Parameters**
**marker** (SimStateMarker)

**analyze**()

**Return type**
bool

**find_best_hypothesis_path**()

**Return type**
tuple[int, ...]

**diagnose_unsat**(*state*)

**Parameters**
**state** (SimState)

**test_path**(*bbl_addr_trace*)

**Return type**
*TestPathReport*

**Parameters**
**bbl_addr_trace** (*tuple[int, ...]*)

angr.analyses.pathfinder.**find_successor**(*successors*, *target_addr*)

**Return type**
tuple[*SimState* | None, *SuccessorsKind*]

**Parameters**

- **successors** (SimSuccessors)
- **target_addr** (*int*)

### 10.3.37 angr.analyses.propagator

**class** angr.analyses.propagator.**PropagatorAnalysis**

Bases: *ForwardAnalysis*, *Analysis*

PropagatorAnalysis implements copy propagation. It propagates values (either constant values or variables) and expressions inside a block or across a function.

PropagatorAnalysis only supports VEX. For AIL, please use SPropagator.

PropagatorAnalysis performs certain arithmetic operations between constants, including but are not limited to:

- addition
- subtraction
- multiplication

- division
- xor

It also performs the following memory operations:

- Loading values from a known address
- Writing values to a stack variable

**property prop_key:** `tuple[str | None, str, int, bool, bool, bool]`

Gets a key that represents the function and the "flavor" of the propagation result.

**property replacements**

### Submodules

*engine_base*
*engine_vex*
*propagator*
*top_checker_mixin*
*values*
*vex_vars*

### angr.analyses.propagator.engine_base

**class** angr.analyses.propagator.engine_base.**SimEnginePropagatorBaseMixin**

Bases: *SimEngineLight*[StateType, DataType_co, BlockType, StateType], Generic[StateType, DataType_co, BlockType]

The base class for the propagator VEX engine.

**__init__**(*project*, *stack_pointer_tracker=None*, *propagate_tmps=True*, *reaching_definitions=None*, *bp_as_gpr=False*)

**Parameters**

- **project** (Project)
- **reaching_definitions** (ReachingDefinitionsModel | *None*)
- **bp_as_gpr** (*bool*)

**process**(*state*, ***, *block=None*, *base_state=None*, *load_callback=None*, ***kwargs*)

**Return type**
StateType

**Parameters**

- **state** (StateType)
- **block** (*BlockType* | *None*)

### angr.analyses.propagator.engine_vex

**class** angr.analyses.propagator.engine_vex.**SimEnginePropagatorVEX**

Bases: *ClaripyDataVEXEngineMixin*[*PropagatorVEXState*, BV, *PropagatorVEXState*, None], *SimEnginePropagatorBaseMixin*[*PropagatorVEXState*, BV, *Block*], *SimEngineNostmtVEX*[*PropagatorVEXState*, BV, *PropagatorVEXState*]

### angr.analyses.propagator.propagator

**class** angr.analyses.propagator.propagator.**PropagatorAnalysis**

Bases: *ForwardAnalysis*, *Analysis*

PropagatorAnalysis implements copy propagation. It propagates values (either constant values or variables) and expressions inside a block or across a function.

PropagatorAnalysis only supports VEX. For AIL, please use SPropagator.

PropagatorAnalysis performs certain arithmetic operations between constants, including but are not limited to:

- addition
- subtraction
- multiplication
- division
- xor

It also performs the following memory operations:

- Loading values from a known address
- Writing values to a stack variable

**property prop_key:** tuple[str | None, str, int, bool, bool, bool]

Gets a key that represents the function and the "flavor" of the propagation result.

**property replacements**

### angr.analyses.propagator.top_checker_mixin

**class** angr.analyses.propagator.top_checker_mixin.**ClaripyDataEngineMixin**

Bases: *SimEngineLight*[StateType, Union[DataType_co, BV], BlockType, ResultType], Generic[StateType, DataType_co, BlockType, ResultType]

**class** angr.analyses.propagator.top_checker_mixin.**ClaripyDataVEXEngineMixin**

Bases: *ClaripyDataEngineMixin*[StateType, DataType_co, *Block*, ResultType], *SimEngineLightVEX*[StateType, Union[DataType_co, BV], ResultType, StmtDataType], Generic[StateType, DataType_co, ResultType, StmtDataType]

### angr.analyses.propagator.values

**class** angr.analyses.propagator.values.**Top**

Bases: object

**__init__**(*size*)

**size**

**property bits**

**class** angr.analyses.propagator.values.**Bottom**

Bases: object

#### angr.analyses.propagator.vex_vars

class angr.analyses.propagator.vex_vars.**VEXVariable**

Bases: object

class angr.analyses.propagator.vex_vars.**VEXMemVar**

Bases: object

**__init__**(*addr*, *size*)

**Parameters**

- **addr** (*int*)
- **size** (*int*)

**addr**

**size**

class angr.analyses.propagator.vex_vars.**VEXReg**

Bases: *VEXVariable*

**__init__**(*offset*, *size*)

**offset**

**size**

class angr.analyses.propagator.vex_vars.**VEXTmp**

Bases: *VEXVariable*

**__init__**(*tmp*)

**tmp**

### 10.3.38 angr.analyses.proximity_graph

class angr.analyses.proximity_graph.**ProxiNodeTypes**

Bases: object

Node Type Enums

**Empty = 0**

**String = 1**

**Function = 2**

**FunctionCall = 3**

**Integer = 4**

**Unknown = 5**

**Variable = 6**

class angr.analyses.proximity_graph.**BaseProxiNode**

Bases: object

Base class for all nodes in a proximity graph.

__init__(*type_*, *ref_at=None*)

**Parameters**

- **type_** (*int*)
- **ref_at** (*set[int] | None*)

class angr.analyses.proximity_graph.**FunctionProxiNode**

Bases: *BaseProxiNode*

Proximity node showing current and expanded function calls in graph.

__init__(*func*, *ref_at=None*)

**Parameters**

- **func** (FuncNode)
- **ref_at** (*set[int] | None*)

class angr.analyses.proximity_graph.**VariableProxiNode**

Bases: *BaseProxiNode*

Variable arg node

__init__(*addr*, *name*, *ref_at=None*)

**Parameters**

**ref_at** (*set[int] | None*)

class angr.analyses.proximity_graph.**StringProxiNode**

Bases: *BaseProxiNode*

String arg node

__init__(*addr*, *content*, *ref_at=None*)

**Parameters**

**ref_at** (*set[int] | None*)

class angr.analyses.proximity_graph.**CallProxiNode**

Bases: *BaseProxiNode*

Call node

__init__(*callee*, *ref_at=None*, *args=None*)

**Parameters**

- **callee** (FuncNode)
- **ref_at** (*set[int] | None*)
- **args** (*tuple[BaseProxiNode] | None*)

class angr.analyses.proximity_graph.**IntegerProxiNode**

Bases: *BaseProxiNode*

Int arg node

__init__(*value*, *ref_at=None*)

**Parameters**

- **value** (*int*)
- **ref_at** (*set[int] | None*)

class angr.analyses.proximity_graph.**UnknownProxiNode**

Bases: *BaseProxiNode*

Unknown arg node

__init__(*dummy_value*)

**Parameters**

**dummy_value** (*str*)

class angr.analyses.proximity_graph.**ProximityGraphAnalysis**

Bases: *Analysis*

Generate a proximity graph.

__init__(*func*, *cfg_model*, *xrefs*, *decompilation=None*, *expand_funcs=None*)

**Parameters**

- **func** (Function)
- **cfg_model** (CFGModel)
- **xrefs** (XRefManager)
- **decompilation** (Decompiler | *None*)
- **expand_funcs** (*set[int] | None*)

**graph: DiGraph | None**

### 10.3.39 angr.analyses.purity

class angr.analyses.purity.**AILPurityAnalysis**

Bases: *Analysis*, *ForwardAnalysisForClinic*[*StateType*]

Determined how data sources are used in a given function.

angr.analyses.purity.**AILPurityDataSource**

alias of *DataSource*

angr.analyses.purity.**AILPurityDataUsage**

alias of *DataUsage*

angr.analyses.purity.**AILPurityResultType**

alias of *ResultType*

#### Submodules

*analysis*
*engine*

### angr.analyses.purity.analysis

class angr.analyses.purity.analysis.**AILPurityAnalysis**

Bases: *Analysis*, *ForwardAnalysisForClinic*[*StateType*]

Determined how data sources are used in a given function.

### angr.analyses.purity.engine

class angr.analyses.purity.engine.**DataUsage**

Bases: object

Facts about a given data source

**ptr_load:** bool = False

**ptr_store:** bool = False

**__init__**(*ptr_load=False*, *ptr_store=False*)

**Parameters**

- **ptr_load** (*bool*)
- **ptr_store** (*bool*)

**Return type**
None

class angr.analyses.purity.engine.**DataSource**

Bases: object

Descriptor of a given data source: where did this value come from?

**constant_value:** int | None = None

**function_arg:** int | None = None

**callee_return:** *Function* | str | None = None

**reference_to:** int | None = None

property **callee_return_name:** str | None

**__init__**(*constant_value=None*, *function_arg=None*, *callee_return=None*, *reference_to=None*)

**Parameters**

- **constant_value** (*int | None*)
- **function_arg** (*int | None*)
- **callee_return** (Function | *str | None*)
- **reference_to** (*int | None*)

**Return type**
None

class angr.analyses.purity.engine.**StateType**

Bases: object

Internal state for purity analysis

**addr:** tuple[int, int]

**vars:** MutableMapping[int, *DataType_co*]

**copy**()

**__init__**(*addr*, *vars*)

**Parameters**

- **addr** (*tuple[int, int]*)
- **vars** (*MutableMapping[int, DataType_co]*)

**Return type**
None

class angr.analyses.purity.engine.**ResultType**

Bases: object

Result of purity analysis - how was each data source used and what function calls arguments were passed?

**uses:** MutableMapping[*DataSource*, *DataUsage*]

**call_args:** MutableMapping[tuple[int, int | None, int, *Function* | str | None, int], *DataType_co*]

**ret_vals:** MutableMapping[int, *DataType_co*]

**other_storage:** MutableMapping[*DataSource*, *DataType_co*]

**update**(*other*)

**Parameters**
**other** (*Self*)

**is_pure**(*pure_functions=None*, *allow_read_arguments=True*, *allow_write_arguments=False*, *allow_read_globals=True*, *allow_write_globals=False*)

**Return type**
bool

**Parameters**

- **pure_functions** (*set[str] | None*)
- **allow_read_arguments** (*bool*)
- **allow_write_arguments** (*bool*)
- **allow_read_globals** (*bool*)
- **allow_write_globals** (*bool*)

**__init__**(*uses=<factory>*, *call_args=<factory>*, *ret_vals=<factory>*, *other_storage=<factory>*)

**Parameters**

- **uses** (*MutableMapping[DataSource, DataUsage]*)
- **call_args** (*MutableMapping[tuple[int, int | None, int, Function | str | None, int], DataType_co]*)
- **ret_vals** (*MutableMapping[int, DataType_co]*)

- **other_storage** (*MutableMapping[DataSource, DataType_co]*)

**Return type**
None

type angr.analyses.purity.engine.**DataType_co** = frozenset[*DataSource*]

type angr.analyses.purity.engine.**StmtDataType** = None

class angr.analyses.purity.engine.**PurityEngineAIL**

Bases: *SimEngineLightAIL*[*StateType*, , , *ResultType*]

Core of this analysis: THIS data source has THESE uses.

A use is arithmetic, store, or load.

**__init__**(*project*, *clinic*, *recurse*)

**Parameters**

- **project** (Project)
- **clinic** (Clinic)
- **recurse** (*Callable[[Function], ResultType]*)

**initial_state**(*node*)

**Parameters**
**node** (*Block*)

**process**(*state*, *, *block=None*, *whitelist=None*, ***kwargs*)

**Return type**
*ResultType*

**Parameters**

- **state** (StateType)
- **block** (*Block | None*)
- **whitelist** (*set[int] | None*)

### 10.3.40 angr.analyses.reaching_definitions

class angr.analyses.reaching_definitions.**Atom**

Bases: object

This class represents a data storage location manipulated by IR instructions.

It could either be a Tmp (temporary variable), a Register, a MemoryLocation.

**__init__**(*size*)

**Parameters**
**size** – The size of the atom in bytes

**size**

property **bits**: int

static **from_ail_expr**(*expr*, *arch*, *full_reg=False*)

**Return type**
*Register*

**Parameters**

- **expr** (Expression)
- **arch** (*Arch*)
- **full_reg** (*bool*)

static **from_argument**(*argument*, *arch*, *full_reg=False*, *sp=None*)

Instantiate an *Atom* from a given argument.

**Parameters**

- **argument** (*SimFunctionArgument*) – The argument to create a new atom from.
- **arch** (Arch) – The argument representing archinfo architecture for argument.
- **full_reg** – Whether to return an atom indicating the entire register if the argument only specifies a slice of the register.
- **sp** (int | None) – The current stack offset. Optional. Only used when argument is a SimStackArg.

**Return type**
*Register* | *MemoryLocation*

static **reg**(*thing*, *size=None*, *arch=None*)

Create a Register atom.

**Parameters**

- **thing** (str | RegisterOffset) – The register offset (e.g., project.arch.registers["rax"][0]) or the register name (e.g., "rax").
- **size** (int | None) – Size of the register atom. Must be provided when creating the atom using a register offset.
- **arch** (Arch | None) – The architecture. Must be provided when creating the atom using a register name.

**Return type**
*Register*

**Returns**
The Register Atom object.

static **register**(*thing*, *size=None*, *arch=None*)

Create a Register atom.

**Parameters**

- **thing** (str | RegisterOffset) – The register offset (e.g., project.arch.registers["rax"][0]) or the register name (e.g., "rax").
- **size** (int | None) – Size of the register atom. Must be provided when creating the atom using a register offset.
- **arch** (Arch | None) – The architecture. Must be provided when creating the atom using a register name.

**Return type**
*Register*

**Returns**
The Register Atom object.

**static mem**(*addr*, *size*, *endness=None*)

Create a MemoryLocation atom,

**Parameters**

- **addr** (*SpOffset* | *HeapAddress* | int) – The memory location. Can be an SpOffset for stack variables, an int for global memory variables, or a HeapAddress for items on the heap.
- **size** (int) – Size of the atom.
- **endness** (Endness | None) – Optional, either "Iend_LE" or "Iend_BE".

**Return type**
*MemoryLocation*

**Returns**
The MemoryLocation Atom object.

**static memory**(*addr*, *size*, *endness=None*)

Create a MemoryLocation atom,

**Parameters**

- **addr** (*SpOffset* | *HeapAddress* | int) – The memory location. Can be an SpOffset for stack variables, an int for global memory variables, or a HeapAddress for items on the heap.
- **size** (int) – Size of the atom.
- **endness** (Endness | None) – Optional, either "Iend_LE" or "Iend_BE".

**Return type**
*MemoryLocation*

**Returns**
The MemoryLocation Atom object.

**class** angr.analyses.reaching_definitions.**AtomKind**

Bases: Enum

An enum indicating the class of an atom

**REGISTER = 1**

**MEMORY = 2**

**TMP = 3**

**GUARD = 4**

**CONSTANT = 5**

**class** angr.analyses.reaching_definitions.**ConstantSrc**

Bases: *Atom*

Represents a constant.

**value:** int

class angr.analyses.reaching_definitions.**Definition**

Bases: Generic[A, CodeLoc]

An atom definition.

**Variables**

- **atom** – The atom being defined.
- **codeloc** – Where this definition is created in the original binary code.
- **dummy** – Tell whether the definition should be considered dummy or not. During simplification by AILment, definitions marked as dummy will not be removed.
- **tags** – A set of tags containing information about the definition gathered during analyses.

__init__(*atom*, *codeloc*, *dummy=False*, *tags=None*)

**Parameters**

- **atom** (*A*)
- **codeloc** (*CodeLoc*)
- **dummy** (*bool*)
- **tags** (*set[Tag] | None*)

**atom**

**codeloc**

**dummy**

**tags**

**property offset: int**

**property size: int**

**matches**(***kwargs*)

Return whether this definition has certain characteristics.

**Return type**
bool

class angr.analyses.reaching_definitions.**FunctionCallData**

Bases: object

A bundle of intermediate data used when computing the sum effect of a function during ReachingDefinitionsAnalysis.

RDA engine contract:

- Construct one of these before calling *FunctionHandler.handle_function*. Fill it with as many fields as you can realistically provide without duplicating effort.
- Provide *callsite_codeloc* as either the call statement (AIL) or the default exit of the default statement of the calling block (VEX)
- Provide *function_codeloc* as the callee address with *stmt_idx=0* `.

Function handler contract:

- If redefine_locals is unset, do not adjust any artifacts of the function call abstraction, such as the stack pointer, the caller saved registers, etc.

- If caller_will_handle_single_ret is set, and there is a single entry in *ret_atoms*, do not apply to the state effects modifying this atom. Instead, set *ret_values* and *ret_values_deps* to the values and deps which are used constructing these values.

**callsite_codeloc:** *CodeLocation*

**function_codeloc:** *CodeLocation*

**address_multi:** *MultiValues* | None

**address:** int | None = None

**symbol:** Symbol | None = None

**function:** *Function* | None = None

**name:** str | None = None

**cc:** *SimCC* | None = None

**prototype:** *SimTypeFunction* | None = None

**args_atoms:** list[set[*Atom*]] | None = None

**args_values:** list[*MultiValues*] | None = None

**ret_atoms:** set[*Atom*] | None = None

**redefine_locals:** bool = True

**visited_blocks:** set[int] | None = None

**effects:** list[*FunctionEffect*]

**ret_values:** *MultiValues* | None = None

**ret_values_deps:** set[*Definition*] | None = None

**caller_will_handle_single_ret:** bool = False

**guessed_cc:** bool = False

**guessed_prototype:** bool = False

**retaddr_popped:** bool = False

**has_clobbered**(*dest*)

Determines whether the given atom already has effects applied

**Return type**
bool

**Parameters**
**dest** (Atom)

**depends**(*dest*, **sources*, *value=None*, *apply_at_callsite=False*, *tags=None*)

Mark a single effect of the current function, including the atom being modified, the input atoms on which that output atom depends, the precise (or imprecise!) value to store, and whether the effect should be applied during the function or afterwards, at the callsite.

The tags are used to annotate the Definition of the Atom that will be created, when the function effects are applied to the state.

The atom being modified may be None to mark uses of the source atoms which do not have any explicit sinks.

**Parameters**

- **dest** (*Atom | Iterable[Atom] | None*)
- **sources** (*Atom | Iterable[Atom]*)
- **value** (*MultiValues | BV | bytes | int | None*)
- **apply_at_callsite** (*bool*)
- **tags** (*set[Tag] | None*)

**reset_prototype**(*prototype*, *state*, *soft_reset=False*)

**Return type**
set[*Atom*]

**Parameters**

- **prototype** (*SimTypeFunction*)
- **state** (*ReachingDefinitionsState*)
- **soft_reset** (*bool*)

**__init__**(*callsite_codeloc*, *function_codeloc*, *address_multi*, *address=None*, *symbol=None*, *function=None*, *name=None*, *cc=None*, *prototype=None*, *args_atoms=None*, *args_values=None*, *ret_atoms=None*, *redefine_locals=True*, *visited_blocks=None*, *effects=<factory>*, *ret_values=None*, *ret_values_deps=None*, *caller_will_handle_single_ret=False*, *guessed_cc=False*, *guessed_prototype=False*, *retaddr_popped=False*)

**Parameters**

- **callsite_codeloc** (*CodeLocation*)
- **function_codeloc** (*CodeLocation*)
- **address_multi** (*MultiValues | None*)
- **address** (*int | None*)
- **symbol** (*Symbol | None*)
- **function** (*Function | None*)
- **name** (*str | None*)
- **cc** (*SimCC | None*)
- **prototype** (*SimTypeFunction | None*)
- **args_atoms** (*list[set[Atom]] | None*)
- **args_values** (*list[MultiValues] | None*)
- **ret_atoms** (*set[Atom] | None*)
- **redefine_locals** (*bool*)
- **visited_blocks** (*set[int] | None*)
- **effects** (*list[FunctionEffect]*)
- **ret_values** (*MultiValues | None*)
- **ret_values_deps** (*set[Definition] | None*)

- **caller_will_handle_single_ret** (*bool*)
- **guessed_cc** (*bool*)
- **guessed_prototype** (*bool*)
- **retaddr_popped** (*bool*)

**Return type**
None

**class** angr.analyses.reaching_definitions.**FunctionCallRelationships**

Bases: object

Produced by the function handler, provides associated callsite info and function input/output definitions.

**callsite:** *CodeLocation*

**target:** int | None

**args_defns:** list[set[*Definition*]]

**other_input_defns:** set[*Definition*]

**ret_defns:** set[*Definition*]

**other_output_defns:** set[*Definition*]

**__init__**(*callsite*, *target*, *args_defns*, *other_input_defns*, *ret_defns*, *other_output_defns*)

**Parameters**

- **callsite** (CodeLocation)
- **target** (*int | None*)
- **args_defns** (*list[set[*Definition*]]*)
- **other_input_defns** (*set[*Definition*]*)
- **ret_defns** (*set[*Definition*]*)
- **other_output_defns** (*set[*Definition*]*)

**Return type**
None

**class** angr.analyses.reaching_definitions.**FunctionHandler**

Bases: object

A mechanism for summarizing a function call's effect on a program for ReachingDefinitionsAnalysis.

**__init__**(*interfunction_level=0*, *extra_impls=None*, *flavor=None*)

**Parameters**

- **interfunction_level** (int) – Maximum depth in to continue local function exploration
- **extra_impls** (Iterable[type[*FunctionHandler*]] | None) – FunctionHandler classes to implement beyond what's implemented in function_handler_library
- **flavor** (str | None) – The decompilation flavor whose callee prototypes are used (None: the analysis's flavor, or the default flavor)

**interfunction_level:** int

**flavor:** `str | None = None`

**hook**(*analysis*)

Attach this instance of the function handler to an instance of RDA.

**Return type**
*FunctionHandler*

**Parameters**
**analysis** (ReachingDefinitionsAnalysis)

**make_function_codeloc**(*target*, *callsite*, *callsite_func_addr*)

The RDA engine will call this function to transform a callsite CodeLocation into a callee CodeLocation.

**Parameters**

- **target** (*int | MultiValues | None*)
- **callsite** (CodeLocation)
- **callsite_func_addr** (*int | None*)

**handle_function**(*state*, *data*)

The main entry point for the function handler. Called with a RDA state and a FunctionCallData, it is expected to update the state and the data as per the contracts described on FunctionCallData.

You can override this method to take full control over how data is processed, or override any of the following to use the higher-level interface (data.depends()):

- *handle_impl_<function name>* - used for <*function name*>.
- *handle_local_function* - used for any function (excluding plt stubs) whose address is inside the main binary.
- *handle_external_function* - used for any function or plt stub whose address is outside the main binary.
- *handle_indirect_function* - used for any function whose target cannot be resolved.
- *handle_generic_function* - used as a default if none of the above are overridden.

Each of them take the same signature as *handle_function*.

**Parameters**

- **state** (ReachingDefinitionsState)
- **data** (FunctionCallData)

**handle_generic_function**(*state*, *data*)

**Parameters**

- **state** (ReachingDefinitionsState)
- **data** (FunctionCallData)

**handle_indirect_function**(*state*, *data*)

**Return type**
None

**Parameters**

- **state** (ReachingDefinitionsState)
- **data** (FunctionCallData)

**handle_local_function**(*state*, *data*)

**Return type**
None

**Parameters**

- **state** (ReachingDefinitionsState)
- **data** (FunctionCallData)

**handle_external_function**(*state*, *data*)

**Return type**
None

**Parameters**

- **state** (ReachingDefinitionsState)
- **data** (FunctionCallData)

**recurse_analysis**(*state*, *data*)

Precondition: `data.function` MUST NOT BE NONE in order to call this method.

**Return type**
None

**Parameters**

- **state** (ReachingDefinitionsState)
- **data** (FunctionCallData)

**static c_args_as_atoms**(*state*, *cc*, *prototype*)

**Return type**
list[set[*Atom*]]

**Parameters**

- **state** (ReachingDefinitionsState)
- **cc** (SimCC)
- **prototype** (SimTypeFunction)

**static c_return_as_atoms**(*state*, *cc*, *prototype*)

**Return type**
set[*Atom*]

**Parameters**

- **state** (ReachingDefinitionsState)
- **cc** (SimCC)
- **prototype** (SimTypeFunction)

**static caller_saved_regs_as_atoms**(*state*, *cc*)

**Return type**
set[*Register*]

**Parameters**

- **state** (ReachingDefinitionsState)

- **cc** (SimCC)

**static stack_pointer_as_atom**(*state*)

**Return type**
*Register*

**class** angr.analyses.reaching_definitions.**GuardUse**

Bases: *Atom*

Implements a guard use.

**target**

**class** angr.analyses.reaching_definitions.**LiveDefinitions**

Bases: object

A LiveDefinitions instance contains definitions and uses for register, stack, memory, and temporary variables, uncovered during the analysis.

**INITIAL_SP_16BIT = 32512**

**INITIAL_SP_32BIT = 2147418112**

**INITIAL_SP_64BIT = 140737488289792**

**__init__**(*arch*, *track_tmps=False*, *canonical_size=8*, *registers=None*, *stack=None*, *memory=None*, *heap=None*, *tmps=None*, *others=None*, *register_uses=None*, *stack_uses=None*, *heap_uses=None*, *memory_uses=None*, *tmp_uses=None*, *other_uses=None*, *element_limit=5*, *merge_into_tops=True*)

**Parameters**

- **arch** (*Arch*)
- **track_tmps** (*bool*)
- **merge_into_tops** (*bool*)

**project:** *Project* | None

**arch**

**track_tmps**

**registers:** *MultiValuedMemory*

**stack:** *MultiValuedMemory*

**memory:** *MultiValuedMemory*

**heap:** *MultiValuedMemory*

**tmps:** dict[int, set[*Definition*]]

**others:** dict[*Atom*, *MultiValues*]

**register_uses**

**stack_uses**

**heap_uses**

**memory_uses**

**tmp_uses:** dict[int, set[*CodeLocation*]]

**other_uses**

**uses_by_codeloc:** dict[*CodeLocation*, set[*Definition*]]

**copy**(*discard_tmpdefs=False*)

**Return type**
*LiveDefinitions*

**reset_uses**()

**static top**(*bits*)

Get a TOP value.

**Parameters**
**bits** (int) – Width of the TOP value (in bits).

**Returns**
The TOP value.

**static is_top**(*expr*)

Check if the given expression is a TOP value.

**Parameters**
**expr** – The given expression.

**Return type**
bool

**Returns**
True if the expression is TOP, False otherwise.

**stack_address**(*offset*)

**Return type**
BV

**Parameters**
**offset** (*int*)

**static is_stack_address**(*addr*)

**Return type**
bool

**Parameters**
**addr** (*Base*)

**static get_stack_offset**(*addr*, *had_stack_base=False*)

**Return type**
int | None

**Parameters**
**addr** (*Base*)

static **annotate_with_def**(*symvar*, *definition*)

**Parameters**

- **symvar** (BV)
- **definition** (*Definition*)

**Return type**
BV

**Returns**

static **extract_defs**(*symvar*)

**Return type**
Generator[*Definition*]

**Parameters**
**symvar** (*Base*)

static **extract_defs_from_annotations**(*annos*)

**Return type**
set[*Definition*]

**Parameters**
**annos** (*Iterable[Annotation]*)

static **extract_defs_from_mv**(*mv*)

**Return type**
Generator[*Definition*]

**Parameters**
**mv** (MultiValues)

**get_sp**()

Return the concrete value contained by the stack pointer.

**Return type**
int

**get_sp_offset**()

Return the offset of the stack pointer.

**Return type**
int | None

**get_stack_address**(*offset*)

**Return type**
int | None

**Parameters**
**offset** (*Base*)

**stack_offset_to_stack_addr**(*offset*)

**Return type**
int

**merge**(**others*)

**Return type**
tuple[*LiveDefinitions*, bool]

**Parameters**
**others** (LiveDefinitions)

**subsumes**(*other*)

**Return type**
bool

**Parameters**
**other** (LiveDefinitions)

**kill_definitions**(*atom*)

Overwrite existing definitions w.r.t 'atom' with a dummy definition instance. A dummy definition will not be removed during simplification.

**Parameters**
**atom** (*Atom*)

**Return type**
None

**Returns**
None

**kill_and_add_definition**(*atom*, *code_loc*, *data*, *dummy=False*, *tags=None*, *endness=None*, *annotated=False*)

**Return type**
*MultiValues* | None

**Parameters**

- **atom** (Atom)
- **code_loc** (CodeLocation)
- **data** (MultiValues)
- **tags** (*set[Tag] | None*)

**add_use**(*atom*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **atom** (Atom)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

**add_use_by_def**(*definition*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **definition** (Definition)
- **code_loc** (CodeLocation)
- **expr** (*Any*)

**get_definitions**(*thing*)

**Return type**
set[Definition[Atom]]

**Parameters**
**thing** (Atom | Definition[Atom] | Iterable[Atom] | Iterable[Definition[Atom]] | MultiValues)

**get_tmp_definitions**(*tmp_idx*)

**Return type**
set[*Definition*]

**Parameters**
**tmp_idx** (*int*)

**get_register_definitions**(*reg_offset*, *size*)

**Return type**
set[*Definition*]

**Parameters**

- **reg_offset** (*int*)
- **size** (*int*)

**get_stack_values**(*stack_offset*, *size*, *endness*)

**Return type**
*MultiValues* | None

**Parameters**

- **stack_offset** (*int*)
- **size** (*int*)
- **endness** (*str*)

**get_stack_definitions**(*stack_offset*, *size*)

**Return type**
set[*Definition*]

**Parameters**

- **stack_offset** (*int*)
- **size** (*int*)

**get_heap_definitions**(*heap_addr*, *size*)

**Return type**
set[*Definition*]

**Parameters**

- **heap_addr** (*int*)

- **size** (*int*)

**get_memory_definitions**(*addr*, *size*)

**Return type**
set[*Definition*]

**Parameters**

- **addr** (*int*)
- **size** (*int*)

**get_values**(*spec*, *endness=None*)

**Return type**
*MultiValues* | None

**Parameters**

- **spec** (*A | Definition[A] | Iterable[A] | Iterable[Definition[A]]*)
- **endness** (*archinfo.Endness | None*)

**get_one_value**(*spec*, *strip_annotations=False*)

**Return type**
BV | None

**Parameters**

- **spec** (*A | Definition[A] | Iterable[A] | Iterable[Definition[A]]*)
- **strip_annotations** (*bool*)

**get_concrete_value**(*spec*, *cast_to=<class 'int'>*)

**Overloads**

- **spec** (A | Definition[A] | Iterable[A] | Iterable[Definition[A]]), **cast_to** (type[int]) → int | None
- **spec** (A | Definition[A] | Iterable[A] | Iterable[Definition[A]]), **cast_to** (type[bytes]) → bytes | None

**Parameters**

- **spec** (*A | Definition[A] | Iterable[A] | Iterable[Definition[A]]*)
- **cast_to** (*type[int | bytes]*)

**Return type**
int | *bytes* | None

**add_register_use**(*reg_offset*, *size*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **reg_offset** (*int*)
- **size** (*int*)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

add_register_use_by_def(*def_*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **def_** (Definition)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

add_stack_use(*atom*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **atom** (MemoryLocation)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

add_stack_use_by_def(*def_*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **def_** (Definition)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

add_heap_use(*atom*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **atom** (MemoryLocation)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

add_heap_use_by_def(*def_*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **def_** (Definition)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

**add_memory_use**(*atom*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **atom** (MemoryLocation)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

**add_memory_use_by_def**(*def_*, *code_loc*, *expr=None*)

**Return type**
None

**Parameters**

- **def_** (Definition)
- **code_loc** (CodeLocation)
- **expr** (*Any | None*)

**add_tmp_use**(*atom*, *code_loc*)

**Return type**
None

**Parameters**

- **atom** (Tmp)
- **code_loc** (CodeLocation)

**add_tmp_use_by_def**(*def_*, *code_loc*)

**Return type**
None

**Parameters**

- **def_** (Definition)
- **code_loc** (CodeLocation)

**deref**(*pointer*, *size*, *endness=Endness.BE*)

**Overloads**

- **pointer** (MultiValues | Atom | Definition[Atom] | Iterable[Atom] | Iterable[Definition[Atom]]), **size** (int | *DerefSize*), **endness** (Endness) = ... → set[*MemoryLocation*]
- **pointer** (int | BV | *HeapAddress* | *SpOffset*), **size** (int | *DerefSize*), **endness** (Endness) = ... → *MemoryLocation* | None

**static is_heap_address**(*addr*)

**Return type**
bool

**Parameters**
**addr** (*Base*)

static get_heap_offset(*addr*)

**Return type**
int | None

**Parameters**
**addr** (*Base*)

heap_address(*offset*)

**Return type**
BV

**Parameters**
**offset** (*int | HeapAddress*)

class angr.analyses.reaching_definitions.**MemoryLocation**

Bases: *Atom*

Represents a memory slice.

It is characterized by its address and its size.

__init__(*addr*, *size*, *endness=None*)

**Parameters**

- **addr** (*SpOffset* | *HeapAddress* | int) – The address of the beginning memory location slice.
- **size** (int) – The size of the represented memory location, in bytes.
- **endness** (*Endness | None*)

**addr:** *SpOffset* | int | BV

**endness**

property **is_on_stack:** bool

True if this memory location is located on the stack.

property **symbolic:** bool

class angr.analyses.reaching_definitions.**ObservationPointType**

Bases: IntEnum

Enum to replace the previously generic constants This makes it possible to annotate where they are expected by typing something as ObservationPointType instead of Literal[0,1]

**OP_BEFORE = 0**

**OP_AFTER = 1**

__new__(*value*)

class angr.analyses.reaching_definitions.**ReachingDefinitionsAnalysis**

Bases: *ForwardAnalysis*[*ReachingDefinitionsState*, , object, object, object], *Analysis*

ReachingDefinitionsAnalysis is a text-book implementation of a static data-flow analysis that works on either a function or a block. It supports both VEX and AIL. By registering observers to observation points, users may use this analysis to generate use-def chains, def-use chains, and reaching definitions, and perform other traditional data-flow analyses such as liveness analysis.

- I've always wanted to find a better name for this analysis. Now I gave up and decided to live with this name for the foreseeable future (until a better name is proposed by someone else).
- Aliasing is definitely a problem, and I forgot how aliasing is resolved in this implementation. I'll leave this as a post-graduation TODO.
- Some more documentation and examples would be nice.

**__init__**(*subject*, *func_graph=None*, *max_iterations=30*, *track_tmps=False*, *track_consts=True*, *observation_points=None*, *init_state=None*, *init_context=None*, *state_initializer=None*, *cc=None*, *function_handler=None*, *observe_all=False*, *visited_blocks=None*, *dep_graph=True*, *observe_callback=None*, *canonical_size=8*, *stack_pointer_tracker=None*, *use_callee_saved_regs_at_return=True*, *interfunction_level=0*, *track_liveness=True*, *func_addr=None*, *element_limit=5*, *merge_into_tops=True*, *variable_map=None*, *flavor=None*)

**Parameters**

- **subject** (*Subject* | Block | *Block* | *Function* | str) – The subject of the analysis: a function, or a single basic block
- **func_graph** – Alternative graph for function.graph.
- **max_iterations** – The maximum number of iterations before the analysis is terminated.
- **track_tmps** – Whether or not temporary variables should be taken into consideration during the analysis.
- **observation_points** (Iterable[tuple[Literal['insn', 'node', 'stmt', 'exit'], int | tuple[int, int] | tuple[int, int, int], *ObservationPointType*]] | None) – A collection of tuples of ("node"|"insn", ins_addr, OP_TYPE) defining where reaching definitions should be copied and stored. OP_TYPE can be OP_BEFORE or OP_AFTER.
- **init_state** (*ReachingDefinitionsState* | None) – An optional initialization state. The analysis creates and works on a copy. Default to None: the analysis then initialize its own abstract state, based on the given <Subject>.
- **init_context** – If init_state is not given, this is used to initialize the context field of the initial state's CodeLocation. The only default-supported type which may go here is a tuple of integers, i.e. a callstack. Anything else requires a custom FunctionHandler.
- **cc** – Calling convention of the function.
- **function_handler** (*FunctionHandler* | None) – The function handler to update the analysis state and results on function calls.
- **observe_all** – Observe every statement, both before and after.
- **visited_blocks** – A set of previously visited blocks.
- **dep_graph** (*DepGraph* | bool | None) – An initial dependency graph to add the result of the analysis to. Set it to None to skip dependency graph generation.
- **canonical_size** – The sizes (in bytes) that objects with an UNKNOWN_SIZE are treated as for operations where sizes are necessary.
- **dep_graph** – Set this to True to generate a dependency graph for the subject. It will be available as *result.dep_graph*.
- **interfunction_level** (int) – The number of functions we should recurse into. This parameter is only used if function_handler is not provided.
- **track_liveness** (bool) – Whether to track liveness information. This can consume sizeable amounts of RAM on large functions. (e.g. ~15GB for a function with 4k nodes)

- **merge_into_tops** (bool) – Merge known values into TOP if TOP is present. If True: {TOP} V {0xabc} = {TOP} If False: {TOP} V {0xabc} = {TOP, 0xabc}
- **flavor** (str | None) – The decompilation flavor whose prototypes of the function and its callees are used (None: the default flavor).
- **state_initializer** (RDAStateInitializer | *None*)
- **func_addr** (*int* | *None*)
- **element_limit** (*int*)

**property observed_results: dict[tuple[str, int, int], *LiveDefinitions*]**

**property all_definitions**

**property all_uses**

**property one_result**

**property dep_graph: *DepGraph***

**property visited_blocks**

**get_reaching_definitions_by_insn**(*ins_addr*, *op_type*)

**get_reaching_definitions_by_node**(*node_addr*, *op_type*)

**node_observe**(*node_addr*, *state*, *op_type*, *node_idx=None*)

**Parameters**

- **node_addr** (int) – Address of the node.
- **state** (*ReachingDefinitionsState*) – The analysis state.
- **op_type** (*ObservationPointType*) – Type of the observation point. Must be one of the following: OP_BEFORE, OP_AFTER.
- **node_idx** (int | None) – ID of the node. Used in AIL to differentiate blocks with the same address.

**Return type**
None

**insn_observe**(*insn_addr*, *stmt*, *block*, *state*, *op_type*)

**Parameters**

- **insn_addr** (int) – Address of the instruction.
- **stmt** (*Statement* | IRStmt) – The statement.
- **block** (*Block* | Block) – The current block.
- **state** (*ReachingDefinitionsState*) – The abstract analysis state.
- **op_type** (*ObservationPointType*) – Type of the observation point. Must be one of the following: OP_BEORE, OP_AFTER.

**Return type**
None

**stmt_observe**(*stmt_idx*, *stmt*, *block*, *state*, *op_type*)

**Parameters**

- **stmt_idx** (int)
- **stmt** (*Statement* | IRStmt)
- **block** (*Block* | Block)
- **state** (*ReachingDefinitionsState*)
- **op_type** (*ObservationPointType*)

**Return type**
None

**Returns**

**exit_observe**(*node_addr*, *exit_stmt_idx*, *block*, *state*, *node_idx=None*)

**Parameters**

- **node_addr** (*int*)
- **exit_stmt_idx** (*int*)
- **block** (Block | *Block*)
- **state** (ReachingDefinitionsState)
- **node_idx** (*int* | *None*)

**property subject**

**callsites_to**(*target*)

**Return type**
Iterable[*FunctionCallRelationships*]

**Parameters**
**target** (*int* | *str* | Function)

**class** angr.analyses.reaching_definitions.**ReachingDefinitionsModel**

Bases: object

Models the definitions, uses, and memory of a ReachingDefinitionState object

**__init__**(*func_addr=None*, *track_liveness=True*)

**Parameters**

- **func_addr** (*int* | *None*)
- **track_liveness** (*bool*)

**add_def**(*d*)

**Return type**
None

**Parameters**
**d** (Definition)

**kill_def**(*d*)

**Return type**
None

**Parameters**
**d** (Definition)

**at_new_stmt**(*codeloc*)

**Return type**
None

**Parameters**
**codeloc** (CodeLocation)

**at_new_block**(*code_loc*, *pred_codelocs*)

**Return type**
None

**Parameters**

- **code_loc** (CodeLocation)
- **pred_codelocs** (*list*[CodeLocation])

**make_liveness_snapshot**()

**Return type**
None

**find_defs_at**(*code_loc*, *op=ObservationPointType.OP_BEFORE*)

**Return type**
set[*Definition*]

**Parameters**

- **code_loc** (CodeLocation)
- **op** (*int*)

**get_defs**(*atom*, *code_loc*, *op*)

**Return type**
set[*Definition*]

**Parameters**

- **atom** (Atom)
- **code_loc** (CodeLocation)
- **op** (*int*)

**copy**()

**Return type**
*ReachingDefinitionsModel*

**merge**(*model*)

**Parameters**
**model** (ReachingDefinitionsModel)

get_observation_by_insn(*ins_addr*, *kind*)

**Return type**
*LiveDefinitions* | None

**Parameters**

- **ins_addr** (*int* | CodeLocation)
- **kind** (ObservationPointType)

get_observation_by_node(*node_addr*, *kind*, *node_idx=None*)

**Return type**
*LiveDefinitions* | None

**Parameters**

- **node_addr** (*int* | CodeLocation)
- **kind** (ObservationPointType)
- **node_idx** (*int* | *None*)

get_observation_by_stmt(*arg1*, *arg2*, *arg3=None*, ***, *block_idx=None*)

**Overloads**

- **codeloc** (*CodeLocation*), **kind** () → *LiveDefinitions* | None
- **node_addr** (int), **stmt_idx** (int), **kind** (), *, **block_idx** (int | None) = None

get_observation_by_exit(*node_addr*, *stmt_idx*, *src_node_idx=None*)

**Return type**
*LiveDefinitions* | None

**Parameters**

- **node_addr** (*int*)
- **stmt_idx** (*int*)
- **src_node_idx** (*int* | *None*)

class angr.analyses.reaching_definitions.**ReachingDefinitionsState**

Bases: object

Represents the internal state of the ReachingDefinitionsAnalysis.

It contains a data class LiveDefinitions, which stores both definitions and uses for register, stack, memory, and temporary variables, uncovered during the analysis.

**Parameters**

- **subject** (*Subject*) – The subject being analyzed.
- **track_tmps** (bool) – Only tells whether or not temporary variables should be taken into consideration when representing the state of the analysis. Should be set to true when the analysis has counted uses and definitions for temporary variables, false otherwise.
- **analysis** (*ReachingDefinitionsAnalysis*) – The analysis that generated the state represented by this object.
- **rtoc_value** – When the targeted architecture is ppc64, the initial function needs to know the *rtoc_value*.

- **live_definitions** (*LiveDefinitions* | None)
- **canonical_size** (int) – The sizes (in bytes) that objects with an UNKNOWN_SIZE are treated as for operations where sizes are necessary.
- **heap_allocator** (*HeapAllocator* | None) – Mechanism to model the management of heap memory.
- **environment** (*Environment* | None) – Representation of the environment of the analyzed program.

**Variables**

**arch** (Arch) – The architecture targeted by the program.

__init__(*codeloc*, *arch*, *subject*, *analysis*, *track_tmps=False*, *track_consts=False*, *rtoc_value=None*, *live_definitions=None*, *canonical_size=8*, *heap_allocator=None*, *environment=None*, *sp_adjusted=False*, *all_definitions=None*, *initializer=None*, *element_limit=5*, *merge_into_tops=True*)

**Parameters**

- **codeloc** (CodeLocation)
- **arch** (*archinfo.Arch*)
- **subject** (Subject)
- **analysis** (ReachingDefinitionsAnalysis)
- **track_tmps** (*bool*)
- **track_consts** (*bool*)
- **live_definitions** (LiveDefinitions | *None*)
- **canonical_size** (*int*)
- **heap_allocator** (HeapAllocator | *None*)
- **environment** (Environment | *None*)
- **sp_adjusted** (*bool*)
- **all_definitions** (*set[*Definition*[A, CodeLoc]]* | *None*)
- **initializer** (RDAStateInitializer | *None*)
- **element_limit** (*int*)
- **merge_into_tops** (*bool*)

**codeloc**

**arch: Arch**

**analysis**

**all_definitions: set[*Definition*[Any, Any]]**

**heap_allocator**

**codeloc_uses: set[*Definition*[Any, Any]]**

**exit_observed: bool**

**live_definitions**

**top**(*bits*)

**Parameters**
**bits** (*int*)

**is_top**(**args*)

**heap_address**(*offset*)

**Return type**
BV

**Parameters**
**offset** (*int* | HeapAddress)

**static is_heap_address**(*addr*)

**Return type**
bool

**Parameters**
**addr** (*Base*)

**static get_heap_offset**(*addr*)

**Return type**
int | None

**Parameters**
**addr** (*Base*)

**stack_address**(*offset*)

**Return type**
BV

**Parameters**
**offset** (*int*)

**is_stack_address**(*addr*)

**Return type**
bool

**Parameters**
**addr** (*Base*)

**get_stack_offset**(*addr*)

**Return type**
int | None

**Parameters**
**addr** (*Base*)

**annotate_with_def**(*symvar*, *definition*)

**Parameters**

- **symvar** (BV)
- **definition** (*Definition*[Any, Any])

**Return type**
BV

**Returns**

**annotate_mv_with_def**(*mv*, *definition*)

**Return type**
*MultiValues*

**Parameters**

- **mv** (MultiValues)
- **definition** (Definition[*A*, *CodeLoc*])

**extract_defs**(*symvar*)

**Return type**
Iterator[*Definition*[Any, Any]]

**Parameters**
**symvar** (*Base*)

**property tmps**

**property tmp_uses**

**property registers: *MultiValuedMemory***

**property register_uses**

**property stack: *MultiValuedMemory***

**property stack_uses**

**property heap: *MultiValuedMemory***

**property heap_uses**

**property memory: *MultiValuedMemory***

**property memory_uses**

**property others: dict[*Atom*, *MultiValues*]**

**property uses_by_codeloc**

**get_sp**()

**Return type**
int

**get_stack_address**(*offset*)

**Return type**
int | None

**Parameters**
**offset** (*Base*)

**property environment**

**property dep_graph**

**copy**(*discard_tmpdefs=False*)

**Return type**
Self

**merge**(**others*)

**Return type**
tuple[Self, bool]

**Parameters**
**others** (*Self*)

**subsumes**(*other*)

**Return type**
bool

**Parameters**
**other** (ReachingDefinitionsState)

**move_codelocs**(*new_codeloc*)

**Return type**
None

**Parameters**
**new_codeloc** (CodeLocation)

**kill_definitions**(*atom*)

Overwrite existing definitions w.r.t 'atom' with a dummy definition instance. A dummy definition will not be removed during simplification.

**Return type**
None

**Parameters**
**atom** (Atom)

**kill_and_add_definition**(*atom*, *data*, *dummy=False*, *tags=None*, *endness=None*, *annotated=False*, *uses=None*, *override_codeloc=None*)

**Return type**
tuple[*MultiValues* | None, set[*Definition*[, ]]]

**Parameters**

- **atom** (Atom)
- **data** (MultiValues)
- **tags** (*set[Tag] | None*)
- **annotated** (*bool*)
- **uses** (*set[Definition[A, CodeLoc]] | None*)
- **override_codeloc** (*CodeLocation | None*)

add_use(*atom*, *expr=None*)

**Return type**
None

**Parameters**

- **atom** (Atom)
- **expr** (*Any | None*)

add_use_by_def(*definition*, *expr=None*)

**Return type**
None

**Parameters**

- **definition** (Definition[*A, CodeLoc*])
- **expr** (*Any | None*)

add_tmp_use(*tmp*, *expr=None*)

**Return type**
None

**Parameters**

- **tmp** (*int*)
- **expr** (*Any | None*)

add_tmp_use_by_defs(*defs*, *expr=None*)

**Return type**
None

**Parameters**

- **defs** (*Iterable*[Definition[*A, CodeLoc*]])
- **expr** (*Any | None*)

add_register_use(*reg_offset*, *size*, *expr=None*)

**Return type**
None

**Parameters**

- **reg_offset** (*int*)
- **size** (*int*)
- **expr** (*Any | None*)

add_register_use_by_defs(*defs*, *expr=None*)

**Return type**
None

**Parameters**

- **defs** (*Iterable*[Definition[*A, CodeLoc*]])
- **expr** (*Any | None*)

**add_stack_use**(*stack_offset*, *size*, *expr=None*)

**Return type**
None

**Parameters**

- **stack_offset** (*int*)
- **size** (*int*)
- **expr** (*Any | None*)

**add_stack_use_by_defs**(*defs*, *expr=None*)

**Parameters**

- **defs** (*Iterable[Definition[A, CodeLoc]]*)
- **expr** (*Any | None*)

**add_heap_use**(*heap_offset*, *size*, *expr=None*)

**Return type**
None

**Parameters**

- **heap_offset** (*int*)
- **size** (*int*)
- **expr** (*Any | None*)

**add_heap_use_by_defs**(*defs*, *expr=None*)

**Parameters**

- **defs** (*Iterable[Definition[A, CodeLoc]]*)
- **expr** (*Any | None*)

**add_memory_use_by_def**(*definition*, *expr=None*)

**Parameters**

- **definition** (*Definition[A, CodeLoc]*)
- **expr** (*Any | None*)

**add_memory_use_by_defs**(*defs*, *expr=None*)

**Parameters**

- **defs** (*Iterable[Definition[A, CodeLoc]]*)
- **expr** (*Any | None*)

**get_definitions**(*atom*)

**Return type**
set[*Definition*[*Atom*, ]]

**Parameters**
**atom** (*Atom | Definition[Atom, CodeLoc] | Iterable[Atom] | Iterable[Definition[Atom, CodeLoc]] | MultiValues*)

**get_values**(*spec*)

**Return type**
*MultiValues* | None

**Parameters**
**spec** (*A* | Definition[*A*, *CodeLoc*] | *Iterable*[*A*])

**get_one_value**(*spec*, *strip_annotations=False*)

**Return type**
BV | None

**Parameters**

- **spec** (*A* | Definition[*A*, *CodeLoc*] | *Iterable*[*A*] | *Iterable*[Definition[*A*, *CodeLoc*]])
- **strip_annotations** (*bool*)

**get_concrete_value**(*spec*, *cast_to=<class 'int'>*)

**Overloads**

- **spec** (Union[*Atom*, *Definition*[*Atom*, ], Iterable[*Atom*]]), **cast_to** (type[int]) → int | None
- **spec** (Union[*Atom*, *Definition*[*Atom*, ], Iterable[*Atom*]]), **cast_to** (type[bytes]) → bytes | None

**Parameters**

- **spec** (Atom | Definition[Atom, *CodeLoc*] | *Iterable*[Atom])
- **cast_to** (type[*int* | bytes])

**Return type**
int | *bytes* | None

**mark_guard**(*target*)

**mark_const**(*value*, *size*)

**Parameters**

- **value** (*int*)
- **size** (*int*)

**downsize**()

**deref**(*pointer*, *size*, *endness=Endness.BE*)

**Overloads**

- **pointer** (int | BV | *HeapAddress* | *SpOffset*), **size** (int | *DerefSize*), **endness** (Endness) = ... → *MemoryLocation* | None
- **pointer** (Union[*MultiValues*, , *Definition*, Iterable[], Iterable[*Definition*[, ]]]), **size** (int | *DerefSize*), **endness** (Endness) = ... → set[*MemoryLocation*]

**Parameters**

- **pointer** (MultiValues | Atom | Definition[Atom, *CodeLoc*] | *Iterable*[Atom] | *Iterable*[Definition[Atom, *CodeLoc*]] | *int* | *BV* | HeapAddress | SpOffset)

- **size** (*int* | DerefSize)
- **endness** (*Endness*)

**class** angr.analyses.reaching_definitions.**Register**

Bases: *Atom*

Represents a given CPU register.

As an IR abstracts the CPU design to target different architectures, registers are represented as a separated memory space. Thus a register is defined by its offset from the base of this memory and its size.

**Variables**

- **reg_offset** (*int*) – The offset from the base to define its place in the memory bloc.
- **size** (*int*) – The size, in number of bytes.

**reg_offset**

**name**(*arch*)

**Return type**
str

**Parameters**
**arch** (*Arch*)

**class** angr.analyses.reaching_definitions.**Tmp**

Bases: *Atom*

Represents a variable used by the IR to store intermediate values.

**tmp_idx**

angr.analyses.reaching_definitions.**get_all_definitions**(*region*)

**Return type**
set[*Definition*]

**Parameters**
**region** (MultiValuedMemory)

### angr.analyses.reaching_definitions.call_trace

**class** angr.analyses.reaching_definitions.call_trace.**CallSite**

Bases: object

Describes a call site on a CFG.

**__init__**(*caller_func_addr*, *block_addr*, *callee_func_addr*)

**Parameters**

- **caller_func_addr** (*int*)
- **block_addr** (*int | None*)
- **callee_func_addr** (*int*)

**caller_func_addr**

**callee_func_addr**

**block_addr**

**class** angr.analyses.reaching_definitions.call_trace.**CallTrace**

Bases: object

Describes a series of functions calls to get from one function (current_function_address()) to another function or a basic block (self.target).

**__init__**(*target*)

**Parameters**
**target** (*int*)

**target**

**callsites: list[*CallSite*]**

**current_function_address**()

**Return type**
int

**step_back**(*caller_func_addr*, *block_addr*, *callee_func_addr*)

**Return type**
*CallTrace*

**Parameters**

- **caller_func_addr** (*int*)
- **block_addr** (*int | None*)

**includes_function**(*func_addr*)

**Return type**
bool

**Parameters**
**func_addr** (*int*)

**copy**()

**Return type**
*CallTrace*

### angr.analyses.reaching_definitions.dep_graph

**class** angr.analyses.reaching_definitions.dep_graph.**DepGraph**

Bases: object

The representation of a dependency graph: a directed graph, where nodes are definitions, and edges represent uses.

Mostly a wrapper around a <networkx.DiGraph>.

**__init__**(*graph=None*)

**Parameters**
**graph** (networkx.DiGraph[Definition] | None) – A graph where nodes are definitions, and edges represent uses.

**property graph: networkx.DiGraph[Definition]**

**add_node**(*node*)

**Parameters**
**node** (*Definition*) – The definition to add to the definition-use graph.

**Return type**
None

**add_edge**(*source*, *destination*, ***labels*)

The edge to add to the definition-use graph. Will create nodes that are not yet present.

**Parameters**

- **source** (*Definition*) – The “source” definition, used by the “destination”.
- **destination** (*Definition*) – The “destination” definition, using the variable defined by “source”.
- **labels** – Optional keyword arguments to represent edge labels.

**Return type**
None

**nodes**()

**Return type**
Iterator[*Definition*]

**predecessors**(*node*)

**Parameters**
**node** (*Definition*) – The definition to get the predecessors of.

**Return type**
Iterator[*Definition*]

**transitive_closure**(*definition*)

Compute the “transitive closure” of a given definition. Obtained by transitively aggregating the ancestors of this definition in the graph.

Note: Each definition is memoized to avoid any kind of recomputation across the lifetime of this object.

**Parameters**
**definition** (Definition[Atom]) – The Definition to get transitive closure for.

**Return type**
networkx.DiGraph[Definition[Atom]]

**Returns**
A graph of the transitive closure of the given definition.

`contains_atom`(*atom*)

**Return type**
bool

**Parameters**
**atom** (Atom)

`add_dependencies_for_concrete_pointers_of`(*values*, *definition*, *cfg*, *loader*)

When a given definition holds concrete pointers, make sure the <MemoryLocation>s they point to are present in the dependency graph; Adds them if necessary.

**Parameters**

- **values** (Iterable[Base | int])
- **definition** (*Definition*) – The definition which has data that can contain concrete pointers.
- **cfg** (*CFGModel* | None) – The CFG, containing information about memory data.
- **loader** (Loader)

`find_definitions`(***kwargs*)

Filter the definitions present in the graph based on various criteria. Parameters can be any valid keyword args to *DefinitionMatchPredicate*

**Overloads**

- *, **kind** (type[]), ****kwargs** () → list[Definition[A]]
- *, **kind** (Literal[*AtomKind.REGISTER*]) = AtomKind.REGISTER, ****kwargs** () → list[Definition[Register]]
- *, **kind** (Literal[*AtomKind.MEMORY*]) = AtomKind.MEMORY, ****kwargs** () → list[Definition[MemoryLocation]]
- *, **kind** (Literal[*AtomKind.TMP*]) = AtomKind.TMP, ****kwargs** () → list[Definition[Tmp]]
- *, **kind** (Literal[*AtomKind.CONSTANT*]) = AtomKind.CONSTANT, ****kwargs** () → list[Definition[ConstantSrc]]
- *, **kind** (Literal[*AtomKind.GUARD*]) = AtomKind.GUARD, ****kwargs** () → list[Definition[GuardUse]]
- *, **reg_name** (int | str) = ..., ****kwargs** () → list[Definition[Register]]
- *, **stack_offset** (int) = ..., ****kwargs** () → list[Definition[MemoryLocation]]
- *, **const_val** (int) = ..., ****kwargs** () → list[Definition[ConstantSrc]]

**Return type**
list[Definition]

`find_all_predecessors`(*starts*, ***kwargs*)

Filter the ancestors of the given start node or nodes that match various criteria. Parameters can be any valid keyword args to *DefinitionMatchPredicate*

**Overloads**

- **starts** (Definition[Atom] | Iterable[Definition[Atom]]), *, **kind** (type[]), ****kwargs** () → list[Definition[A]]
- **starts** (Definition[Atom] | Iterable[Definition[Atom]]), *, **kind** (Literal[*AtomKind.REGISTER*]) = AtomKind.REGISTER, ****kwargs** () → list[Definition[Register]]
- **starts** (Definition[Atom] | Iterable[Definition[Atom]]), *, **kind** (Literal[*AtomKind.MEMORY*]) = AtomKind.MEMORY, ****kwargs** () → list[Definition[MemoryLocation]]
- **starts** (Definition[Atom] | Iterable[Definition[Atom]]), *, **kind** (Literal[*AtomKind.TMP*]) = AtomKind.TMP, ****kwargs** () → list[Definition[Tmp]]
- **starts** (Definition[Atom] | Iterable[Definition[Atom]]), *, **kind** (Literal[*AtomKind.CONSTANT*]) = AtomKind.CONSTANT, ****kwargs** () → list[Definition[ConstantSrc]]
- **starts** (Definition[Atom] | Iterable[Definition[Atom]]), *, **kind** (Literal[*AtomKind.GUARD*]) = AtomKind.GUARD, ****kwargs** () → list[Definition[GuardUse]]
- **starts** (Definition[Atom] | Iterable[Definition[Atom]]), *, **reg_name** (int | str) = ..., ****kwargs** () → list[Definition[Register]]
- **starts** (Definition[Atom] | Iterable[Definition[Atom]]), *, **stack_offset** (int) = ..., ****kwargs** () → list[Definition[MemoryLocation]]
- **starts** (Definition[Atom] | Iterable[Definition[Atom]]), *, **const_val** (int) = ..., ****kwargs** () → list[Definition[ConstantSrc]]

**find_all_successors**(*starts*, ***kwargs*)

Filter the descendents of the given start node or nodes that match various criteria. Parameters can be any valid keyword args to *DefinitionMatchPredicate*

**Return type**
list[*Definition*]

**Parameters**
**starts** (Definition | *Iterable*[Definition])

**find_path**(*starts*, *ends*, ***kwargs*)

Find a path between the given start node or nodes and the given end node or nodes. All the intermediate steps in the path must match the criteria given in kwargs. The kwargs can be any valid parameters to *DefinitionMatchPredicate*.

This algorithm has exponential time and space complexity. Use at your own risk. Want to do better? Do it yourself or use networkx and eat the cost of indirection and/or cloning.

**Return type**
tuple[*Definition*, ...] | None

**Parameters**

- **starts** (Definition | *Iterable*[Definition])
- **ends** (Definition | *Iterable*[Definition])

**find_paths**(*starts*, *ends*, ***kwargs*)

Find all non-overlapping simple paths between the given start node or nodes and the given end node or nodes. All the intermediate steps in the path must match the criteria given in kwargs. The kwargs can be any valid parameters to *DefinitionMatchPredicate*.

This algorithm has exponential time and space complexity. Use at your own risk. Want to do better? Do it yourself or use networkx and eat the cost of indirection and/or cloning.

**Return type**
Iterator[tuple[*Definition*, ...]]

**Parameters**

- **starts** (Definition | *Iterable*[Definition])
- **ends** (Definition | *Iterable*[Definition])

### angr.analyses.reaching_definitions.engine_ail

**class** angr.analyses.reaching_definitions.engine_ail.**SimEngineRDAIL**

Bases: *SimEngineNostmtAIL*[*ReachingDefinitionsState*, *MultiValues*, None, *ReachingDefinitionsState*]

**__init__**(*project*, *function_handler*, *stack_pointer_tracker=None*, *use_callee_saved_regs_at_return=True*, *bp_as_gpr=False*, *variable_map=None*)

**Parameters**

- **function_handler** (FunctionHandler)
- **bp_as_gpr** (*bool*)

**process**(*state*, ***, *dep_graph=None*, *visited_blocks=None*, *block=None*, *fail_fast=False*, *whitelist=None*, ***kwargs*)

### angr.analyses.reaching_definitions.engine_vex

**class** angr.analyses.reaching_definitions.engine_vex.**SimEngineRDVEX**

Bases: *SimEngineNostmtVEX*[*ReachingDefinitionsState*, *MultiValues*, *ReachingDefinitionsState*]

Implements the VEX execution engine for reaching definition analysis.

**__init__**(*project*, *function_handler*, *functions*)

**Parameters**

- **function_handler** (FunctionHandler)
- **functions** (FunctionManager)

**process**(*state*, ***, *block=None*, *fail_fast=False*, *visited_blocks=None*, *dep_graph=None*, *whitelist=None*, ***kwargs*)

### angr.analyses.reaching_definitions.external_codeloc

### angr.analyses.reaching_definitions.function_handler

angr.analyses.reaching_definitions.function_handler.**get_exit_livedefinitions**(*func*, *rda_model*)

Get LiveDefinitions at all exits of a function, merge them, and return.

**Parameters**

- **func** (Function)
- **rda_model** (ReachingDefinitionsModel)

class angr.analyses.reaching_definitions.function_handler.**FunctionEffect**

Bases: object

A single effect that a function summary may apply to the state. This is largely an implementation detail; use *FunctionCallData.depends* instead.

**dest:** *Atom* | None

**sources:** set[*Atom*]

**value:** *MultiValues* | None = None

**sources_defns:** set[*Definition*] | None = None

**apply_at_callsite:** bool = False

**tags:** set[*Tag*] | None = None

**__init__**(*dest*, *sources*, *value=None*, *sources_defns=None*, *apply_at_callsite=False*, *tags=None*)

**Parameters**

- **dest** (*Atom | None*)
- **sources** (*set[Atom]*)
- **value** (*MultiValues | None*)
- **sources_defns** (*set[Definition] | None*)
- **apply_at_callsite** (*bool*)
- **tags** (*set[Tag] | None*)

**Return type**
None

class angr.analyses.reaching_definitions.function_handler.**FunctionCallData**

Bases: object

A bundle of intermediate data used when computing the sum effect of a function during ReachingDefinitions-Analysis.

RDA engine contract:

- Construct one of these before calling *FunctionHandler.handle_function*. Fill it with as many fields as you can realistically provide without duplicating effort.
- Provide *callsite_codeloc* as either the call statement (AIL) or the default exit of the default statement of the calling block (VEX)
- Provide *function_codeloc* as the callee address with *stmt_idx=0* `.

Function handler contract:

- If redefine_locals is unset, do not adjust any artifacts of the function call abstraction, such as the stack pointer, the caller saved registers, etc.
- If caller_will_handle_single_ret is set, and there is a single entry in *ret_atoms*, do not apply to the state effects modifying this atom. Instead, set *ret_values* and *ret_values_deps* to the values and deps which are used constructing these values.

**callsite_codeloc:** *CodeLocation*

**function_codeloc:** *CodeLocation*

**address_multi:** *MultiValues* | None

**address:** int | None = None

**symbol:** Symbol | None = None

**function:** *Function* | None = None

**name:** str | None = None

**cc:** *SimCC* | None = None

**prototype:** *SimTypeFunction* | None = None

**args_atoms:** list[set[*Atom*]] | None = None

**args_values:** list[*MultiValues*] | None = None

**ret_atoms:** set[*Atom*] | None = None

**redefine_locals:** bool = True

**visited_blocks:** set[int] | None = None

**effects:** list[*FunctionEffect*]

**ret_values:** *MultiValues* | None = None

**ret_values_deps:** set[*Definition*] | None = None

**caller_will_handle_single_ret:** bool = False

**guessed_cc:** bool = False

**guessed_prototype:** bool = False

**retaddr_popped:** bool = False

**has_clobbered**(*dest*)

Determines whether the given atom already has effects applied

**Return type**
bool

**Parameters**
**dest** (Atom)

**depends**(*dest*, **sources*, *value=None*, *apply_at_callsite=False*, *tags=None*)

Mark a single effect of the current function, including the atom being modified, the input atoms on which that output atom depends, the precise (or imprecise!) value to store, and whether the effect should be applied during the function or afterwards, at the callsite.

The tags are used to annotate the Definition of the Atom that will be created, when the function effects are applied to the state.

The atom being modified may be None to mark uses of the source atoms which do not have any explicit sinks.

**Parameters**

- **dest** (Atom | *Iterable*[Atom] | *None*)
- **sources** (Atom | *Iterable*[Atom])
- **value** (MultiValues | *BV* | bytes | *int* | *None*)
- **apply_at_callsite** (*bool*)
- **tags** (*set*[Tag] | *None*)

**reset_prototype**(*prototype*, *state*, *soft_reset=False*)

**Return type**
set[*Atom*]

**Parameters**

- **prototype** (SimTypeFunction)
- **state** (ReachingDefinitionsState)
- **soft_reset** (*bool*)

**__init__**(*callsite_codeloc*, *function_codeloc*, *address_multi*, *address=None*, *symbol=None*, *function=None*, *name=None*, *cc=None*, *prototype=None*, *args_atoms=None*, *args_values=None*, *ret_atoms=None*, *redefine_locals=True*, *visited_blocks=None*, *effects=<factory>*, *ret_values=None*, *ret_values_deps=None*, *caller_will_handle_single_ret=False*, *guessed_cc=False*, *guessed_prototype=False*, *retaddr_popped=False*)

**Parameters**

- **callsite_codeloc** (CodeLocation)
- **function_codeloc** (CodeLocation)
- **address_multi** (MultiValues | *None*)
- **address** (*int* | *None*)
- **symbol** (*Symbol* | *None*)
- **function** (Function | *None*)
- **name** (*str* | *None*)
- **cc** (SimCC | *None*)
- **prototype** (SimTypeFunction | *None*)
- **args_atoms** (*list*[*set*[Atom]] | *None*)
- **args_values** (*list*[MultiValues] | *None*)
- **ret_atoms** (*set*[Atom] | *None*)
- **redefine_locals** (*bool*)
- **visited_blocks** (*set*[*int*] | *None*)
- **effects** (*list*[FunctionEffect])
- **ret_values** (MultiValues | *None*)
- **ret_values_deps** (*set*[Definition] | *None*)
- **caller_will_handle_single_ret** (*bool*)
- **guessed_cc** (*bool*)

- **guessed_prototype** (*bool*)
- **retaddr_popped** (*bool*)

**Return type**
None

**class** angr.analyses.reaching_definitions.function_handler.**FunctionCallDataUnwrapped**

Bases: *FunctionCallData*

A subclass of FunctionCallData which asserts that many of its members are non-None at construction time. Typechecks be gone!

**address_multi:** *MultiValues*

**__init__**(*inner*)

**Parameters**
**inner** (FunctionCallData)

**static decorate**(*wrapper*, *, *wrapped=<function FunctionCallDataUnwrapped.decorate>*, *assigned=('__module__', '__name__', '__qualname__', '__doc__', '__annotations__', '__type_params__')*, *updated=('__dict__', )*)

Update a wrapper function to look like the wrapped function

wrapper is the function to be updated wrapped is the original function assigned is a tuple naming the attributes assigned directly from the wrapped function to the wrapper function (defaults to functools.WRAPPER_ASSIGNMENTS) updated is a tuple naming the attributes of the wrapper that are updated with the corresponding attribute from the wrapped function (defaults to functools.WRAPPER_UPDATES)

**class** angr.analyses.reaching_definitions.function_handler.**FunctionCallRelationships**

Bases: object

Produced by the function handler, provides associated callsite info and function input/output definitions.

**callsite:** *CodeLocation*

**target:** int | None

**args_defns:** list[set[*Definition*]]

**other_input_defns:** set[*Definition*]

**ret_defns:** set[*Definition*]

**other_output_defns:** set[*Definition*]

**__init__**(*callsite*, *target*, *args_defns*, *other_input_defns*, *ret_defns*, *other_output_defns*)

**Parameters**

- **callsite** (CodeLocation)
- **target** (*int | None*)
- **args_defns** (*list[set[Definition]]*)
- **other_input_defns** (*set[Definition]*)
- **ret_defns** (*set[Definition]*)
- **other_output_defns** (*set[Definition]*)

**Return type**
None

**class** angr.analyses.reaching_definitions.function_handler.**FunctionHandler**

Bases: object

A mechanism for summarizing a function call's effect on a program for ReachingDefinitionsAnalysis.

**__init__**(*interfunction_level=0*, *extra_impls=None*, *flavor=None*)

**Parameters**

- **interfunction_level** (int) – Maximum depth in to continue local function exploration
- **extra_impls** (Iterable[type[*FunctionHandler*]] | None) – FunctionHandler classes to implement beyond what's implemented in function_handler_library
- **flavor** (str | None) – The decompilation flavor whose callee prototypes are used (None: the analysis's flavor, or the default flavor)

**interfunction_level:** int

**flavor:** str | None = None

**hook**(*analysis*)

Attach this instance of the function handler to an instance of RDA.

**Return type**
*FunctionHandler*

**Parameters**
**analysis** (ReachingDefinitionsAnalysis)

**make_function_codeloc**(*target*, *callsite*, *callsite_func_addr*)

The RDA engine will call this function to transform a callsite CodeLocation into a callee CodeLocation.

**Parameters**

- **target** (*int* | MultiValues | *None*)
- **callsite** (CodeLocation)
- **callsite_func_addr** (*int* | *None*)

**handle_function**(*state*, *data*)

The main entry point for the function handler. Called with a RDA state and a FunctionCallData, it is expected to update the state and the data as per the contracts described on FunctionCallData.

You can override this method to take full control over how data is processed, or override any of the following to use the higher-level interface (data.depends()):

- *handle_impl_<function name>* - used for *<function name>*.
- *handle_local_function* - used for any function (excluding plt stubs) whose address is inside the main binary.
- *handle_external_function* - used for any function or plt stub whose address is outside the main binary.
- *handle_indirect_function* - used for any function whose target cannot be resolved.
- *handle_generic_function* - used as a default if none of the above are overridden.

Each of them take the same signature as *handle_function*.

**Parameters**

- **state** (ReachingDefinitionsState)
- **data** (FunctionCallData)

**handle_generic_function**(*state*, *data*)

**Parameters**

- **state** (ReachingDefinitionsState)
- **data** (FunctionCallData)

**handle_indirect_function**(*state*, *data*)

**Return type**
None

**Parameters**

- **state** (ReachingDefinitionsState)
- **data** (FunctionCallData)

**handle_local_function**(*state*, *data*)

**Return type**
None

**Parameters**

- **state** (ReachingDefinitionsState)
- **data** (FunctionCallData)

**handle_external_function**(*state*, *data*)

**Return type**
None

**Parameters**

- **state** (ReachingDefinitionsState)
- **data** (FunctionCallData)

**recurse_analysis**(*state*, *data*)

Precondition: `data.function` MUST NOT BE NONE in order to call this method.

**Return type**
None

**Parameters**

- **state** (ReachingDefinitionsState)
- **data** (FunctionCallData)

**static c_args_as_atoms**(*state*, *cc*, *prototype*)

**Return type**
list[set[*Atom*]]

**Parameters**

- **state** (ReachingDefinitionsState)
- **cc** (SimCC)

- **prototype** (SimTypeFunction)

**static c_return_as_atoms**(*state*, *cc*, *prototype*)

**Return type**
set[*Atom*]

**Parameters**

- **state** (ReachingDefinitionsState)
- **cc** (SimCC)
- **prototype** (SimTypeFunction)

**static caller_saved_regs_as_atoms**(*state*, *cc*)

**Return type**
set[*Register*]

**Parameters**

- **state** (ReachingDefinitionsState)
- **cc** (SimCC)

**static stack_pointer_as_atom**(*state*)

**Return type**
*Register*

### angr.analyses.reaching_definitions.function_handler_library.stdio

**class** angr.analyses.reaching_definitions.function_handler_library.stdio.**StdoutAtom**

Bases: *Atom*

**size**

**class** angr.analyses.reaching_definitions.function_handler_library.stdio.**StdinAtom**

Bases: *Atom*

**size**

angr.analyses.reaching_definitions.function_handler_library.stdio.**parse_format_string**(*format_string*)

**Return type**
tuple[list[str | int], list[*SimType*], list[str]]

**Parameters**
**format_string** (*str*)

**class** angr.analyses.reaching_definitions.function_handler_library.stdio.**LibcStdioHandlers**

Bases: *FunctionHandler*

**handle_impl_printf**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_dprintf**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_fprintf**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_sprintf**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_snprintf**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl___sprintf_chk**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl___snprintf_chk**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_scanf**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl___isoc99_scanf()**

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_sscanf()**

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl___isoc99_sscanf()**

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_fgets()**

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_fgetc()**

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_getchar**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_getc**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_fread**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_fwrite**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

angr.analyses.reaching_definitions.function_handler_library.stdio.**handle_printf**(*state*, *data*, *fmt_idx*)

**Return type**
tuple[*MultiValues* | None, Iterable[*Atom*]]

**Parameters**

- **state** (ReachingDefinitionsState)
- **data** (FunctionCallDataUnwrapped)
- **fmt_idx** (*int*)

angr.analyses.reaching_definitions.function_handler_library.stdio.**handle_scanf**(*state*, *data*, *fmt_idx*, *source_atoms*)

**Parameters**

- **state** (ReachingDefinitionsState)
- **data** (FunctionCallDataUnwrapped)
- **fmt_idx** (*int*)
- **source_atoms** (*Iterable[Atom]*)

### angr.analyses.reaching_definitions.function_handler_library.stdlib

**class** angr.analyses.reaching_definitions.function_handler_library.stdlib.**EnvironAtom**

Bases: *Atom*

**size**

**class** angr.analyses.reaching_definitions.function_handler_library.stdlib.**SystemAtom**

Bases: *Atom*

**size**

**class** angr.analyses.reaching_definitions.function_handler_library.stdlib.**ExecveAtom**

Bases: *Atom*

**size**

**class** angr.analyses.reaching_definitions.function_handler_library.stdlib.**LibcStdlibHandlers**

Bases: *FunctionHandler*

**handle_impl_atoi**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_malloc**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_calloc**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_getenv**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_setenv**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_system**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_popen**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_execl**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_execve**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

### angr.analyses.reaching_definitions.function_handler_library.string

**class** angr.analyses.reaching_definitions.function_handler_library.string.**LibcStringHandlers**

Bases: *FunctionHandler*

**handle_impl_strcat**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_strncat**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_strlen**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallData], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_strcpy**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallData], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_strncpy**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallData], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_strdup**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallData], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_memcpy**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallData], None]

**Parameters**
**f** (*Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None]*)

**handle_impl_memset**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (*Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None]*)

**handle_impl_strtok**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (*Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None]*)

**handle_impl_strtok_r**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (*Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None]*)

**handle_impl_strstr**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (*Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None]*)

**handle_impl_strcasestr**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_strchr**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallData], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_imple_strrchr**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallData], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

**handle_impl_strchrnul**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallData], None]

**Parameters**
**f** (Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None])

### angr.analyses.reaching_definitions.function_handler_library.unistd

**class** angr.analyses.reaching_definitions.function_handler_library.unistd.**FDAtom**

Bases: *Atom*

**size**

**class** angr.analyses.reaching_definitions.function_handler_library.unistd.**LibcUnistdHandlers**

Bases: *FunctionHandler*

**handle_impl_read**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallData], None]

**Parameters**
**f** (*Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None]*)

**handle_impl_recv**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (*Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None]*)

**handle_impl_recvfrom**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (*Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None]*)

**handle_impl_write**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (*Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None]*)

**handle_impl_send**()

Decorate a function handler method with this to make it take a FunctionCallDataUnwrapped instead of a FunctionCallData.

**Return type**
Callable[[*FunctionHandler*, *ReachingDefinitionsState*, *FunctionCallData*], None]

**Parameters**
**f** (*Callable[[FunctionHandler, ReachingDefinitionsState, FunctionCallDataUnwrapped], None]*)

### angr.analyses.reaching_definitions.heap_allocator

**class** angr.analyses.reaching_definitions.heap_allocator.**HeapAllocator**

Bases: object

A simple modelisation to help represent heap memory management during a <ReachingDefinitionsAnalysis>: - Act as if allocations were always done in consecutive memory segments; - Take care of the size not to screw potential pointer arithmetic (avoid overlapping segments).

The content of the heap itself is modeled using a <KeyedRegion> attribute in the <LiveDefinitions> state; This class serves to generate consistent heap addresses to be used by the aforementioned.

*Note:* This has **NOT** been made to help detect heap vulnerabilities.

**__init__**(*canonical_size*)

**Parameters**
**canonical_size** (int) – The concrete size an <UNKNOWN_SIZE> defaults to.

**allocate**(*size*)

Gives an address for a new memory chunk of <size> bytes.

**Parameters**
**size** (int | *UnknownSize*) – The requested size for the chunk, in number of bytes.

**Return type**
*HeapAddress*

**Returns**
The address of the chunk.

**free**(*address*)

Mark the chunk pointed by <address> as freed.

**Parameters**
**address** (*Undefined* | *HeapAddress*) – The address of the chunk to free.

**property allocated_addresses**

The list of addresses that are currently allocated on the heap.

**Type**
return

### angr.analyses.reaching_definitions.rd_initializer

**class** angr.analyses.reaching_definitions.rd_initializer.**RDAStateInitializer**

Bases: object

This class acts as the basic implementation for the logic that initializes the base state for the reaching definitions analysis.

It also defines the _interface_ that a state initializer should implement, if the language/runtime being analyzed requires more complicated logic to set up the state.

This code/logic was previously part of the ReachingDefinitionsState class, but this was moved here to separate these two concerns, and allow easily changing the initialization logic without having to change the state class.

**__init__**(*arch*, *project=None*)

**Parameters**
**arch** (*Arch*)

**default_rtoc_value**(*func_addr*)

Derive the initial TOC pointer of the object containing func_addr on PPC64. Returns None if unavailable.

**Return type**
int | None

**Parameters**
**func_addr** (*int*)

**initialize_function_state**(*state*, *cc*, *func_addr*, *rtoc_value=None*)

This is the entry point to the state initialization logic. It will be called during the initialization of an ReachingDefinitionsState, if the state was freshly created (without existing live_definitions)

**Return type**
None

**Parameters**

- **state** (ReachingDefinitionsState)
- **cc** (SimCC | *None*)
- **func_addr** (*int*)
- **rtoc_value** (*int* | *None*)

**initialize_all_function_arguments**(*state*, *func_addr*, *ex_loc*, *cc*, *prototype*)

This method handles the setup for _all_ arguments of a function.

The default implementation uses the calling convention to extract the argument locations, associates them with the type, and passes them to the logic for one argument.

You probably don't need to override this

**Return type**
None

**Parameters**

- **state** (ReachingDefinitionsState)
- **func_addr** (*int*)
- **ex_loc** (ExternalCodeLocation)
- **cc** (SimCC | *None*)
- **prototype** (SimTypeFunction | *None*)

**initialize_one_function_argument**(*state*, *func_addr*, *ex_loc*, *argument_location*, *argument_type=None*)

This method handles the setup for _one_ argument of a function. This is the main method to override for custom initialization logic.

The default implementation initializes only the argument location itself, but the signature allows this to support extra logic based on the _type_ of the argument as well.

For example if the argument is a pointer to something, the default implementation would only set up the register with the value TOP.

A custom implementation could instead dedicate some memory somewhere (e.g. on the heap), setup whatever object is being pointed to, and then put the actual pointer to this inside the register

**Return type**
None

**Parameters**

- **state** (ReachingDefinitionsState)
- **func_addr** (*int*)
- **ex_loc** (ExternalCodeLocation)
- **argument_location** (SimFunctionArgument)

- **argument_type** (SimType | *None*)

**initialize_stack_pointer**(*state*, *_func_addr*, *ex_loc*)

**Return type**
None

**Parameters**

- **state** (ReachingDefinitionsState)
- **_func_addr** (*int*)
- **ex_loc** (ExternalCodeLocation)

**initialize_architectural_state**(*state*, *func_addr*, *ex_loc*, *rtoc_value=None*)

Some architectures require initialization that is specific to that architecture.

Override this if you need to add support for an architecture that requires this, and isn't covered yet

**Return type**
None

**Parameters**

- **state** (ReachingDefinitionsState)
- **func_addr** (*int*)
- **ex_loc** (ExternalCodeLocation)
- **rtoc_value** (*int* | *None*)

### angr.analyses.reaching_definitions.rd_state

**class** angr.analyses.reaching_definitions.rd_state.**ReachingDefinitionsState**

Bases: object

Represents the internal state of the ReachingDefinitionsAnalysis.

It contains a data class LiveDefinitions, which stores both definitions and uses for register, stack, memory, and temporary variables, uncovered during the analysis.

**Parameters**

- **subject** (*Subject*) – The subject being analyzed.
- **track_tmps** (bool) – Only tells whether or not temporary variables should be taken into consideration when representing the state of the analysis. Should be set to true when the analysis has counted uses and definitions for temporary variables, false otherwise.
- **analysis** (*ReachingDefinitionsAnalysis*) – The analysis that generated the state represented by this object.
- **rtoc_value** – When the targeted architecture is ppc64, the initial function needs to know the *rtoc_value*.
- **live_definitions** (*LiveDefinitions* | None)
- **canonical_size** (int) – The sizes (in bytes) that objects with an UNKNOWN_SIZE are treated as for operations where sizes are necessary.
- **heap_allocator** (*HeapAllocator* | None) – Mechanism to model the management of heap memory.

- **environment** (*Environment* | None) – Representation of the environment of the analyzed program.

**Variables**
**arch** (Arch) – The architecture targeted by the program.

**__init__**(*codeloc*, *arch*, *subject*, *analysis*, *track_tmps=False*, *track_consts=False*, *rtoc_value=None*, *live_definitions=None*, *canonical_size=8*, *heap_allocator=None*, *environment=None*, *sp_adjusted=False*, *all_definitions=None*, *initializer=None*, *element_limit=5*, *merge_into_tops=True*)

**Parameters**

- **codeloc** (CodeLocation)
- **arch** (*archinfo.Arch*)
- **subject** (Subject)
- **analysis** (ReachingDefinitionsAnalysis)
- **track_tmps** (*bool*)
- **track_consts** (*bool*)
- **live_definitions** (LiveDefinitions | *None*)
- **canonical_size** (*int*)
- **heap_allocator** (HeapAllocator | *None*)
- **environment** (Environment | *None*)
- **sp_adjusted** (*bool*)
- **all_definitions** (*set[Definition[A, CodeLoc]]* | *None*)
- **initializer** (RDAStateInitializer | *None*)
- **element_limit** (*int*)
- **merge_into_tops** (*bool*)

**codeloc**

**arch**: Arch

**analysis**

**all_definitions**: set[*Definition*[Any, Any]]

**heap_allocator**

**codeloc_uses**: set[*Definition*[Any, Any]]

**exit_observed**: bool

**live_definitions**

**top**(*bits*)

**Parameters**
**bits** (*int*)

**is_top**(**args*)

heap_address(*offset*)

**Return type**
BV

**Parameters**
**offset** (*int | HeapAddress*)

static is_heap_address(*addr*)

**Return type**
bool

**Parameters**
**addr** (*Base*)

static get_heap_offset(*addr*)

**Return type**
int | None

**Parameters**
**addr** (*Base*)

stack_address(*offset*)

**Return type**
BV

**Parameters**
**offset** (*int*)

is_stack_address(*addr*)

**Return type**
bool

**Parameters**
**addr** (*Base*)

get_stack_offset(*addr*)

**Return type**
int | None

**Parameters**
**addr** (*Base*)

annotate_with_def(*symvar*, *definition*)

**Parameters**

- **symvar** (BV)
- **definition** (*Definition*[Any, Any])

**Return type**
BV

**Returns**

annotate_mv_with_def(*mv*, *definition*)

**Return type**
*MultiValues*

**Parameters**

- **mv** (MultiValues)
- **definition** (Definition[*A*, *CodeLoc*])

extract_defs(*symvar*)

**Return type**
Iterator[*Definition*[Any, Any]]

**Parameters**
**symvar** (*Base*)

property tmps

property tmp_uses

property registers: *MultiValuedMemory*

property register_uses

property stack: *MultiValuedMemory*

property stack_uses

property heap: *MultiValuedMemory*

property heap_uses

property memory: *MultiValuedMemory*

property memory_uses

property others: dict[*Atom*, *MultiValues*]

property uses_by_codeloc

get_sp()

**Return type**
int

get_stack_address(*offset*)

**Return type**
int | None

**Parameters**
**offset** (*Base*)

property environment

property dep_graph

**copy**(*discard_tmpdefs=False*)

**Return type**
Self

**merge**(**others*)

**Return type**
tuple[Self, bool]

**Parameters**
**others** (*Self*)

**subsumes**(*other*)

**Return type**
bool

**Parameters**
**other** (ReachingDefinitionsState)

**move_codelocs**(*new_codeloc*)

**Return type**
None

**Parameters**
**new_codeloc** (CodeLocation)

**kill_definitions**(*atom*)

Overwrite existing definitions w.r.t 'atom' with a dummy definition instance. A dummy definition will not be removed during simplification.

**Return type**
None

**Parameters**
**atom** (Atom)

**kill_and_add_definition**(*atom*, *data*, *dummy=False*, *tags=None*, *endness=None*, *annotated=False*, *uses=None*, *override_codeloc=None*)

**Return type**
tuple[*MultiValues* | None, set[*Definition*[, ]]]

**Parameters**

- **atom** (Atom)
- **data** (MultiValues)
- **tags** (*set[Tag] | None*)
- **annotated** (*bool*)
- **uses** (*set[Definition[A, CodeLoc]] | None*)
- **override_codeloc** (*CodeLocation | None*)

**add_use**(*atom*, *expr=None*)

**Return type**
None

**Parameters**

- **atom** (Atom)
- **expr** (*Any | None*)

**add_use_by_def**(*definition*, *expr=None*)

**Return type**
None

**Parameters**

- **definition** (Definition[*A*, *CodeLoc*])
- **expr** (*Any | None*)

**add_tmp_use**(*tmp*, *expr=None*)

**Return type**
None

**Parameters**

- **tmp** (*int*)
- **expr** (*Any | None*)

**add_tmp_use_by_defs**(*defs*, *expr=None*)

**Return type**
None

**Parameters**

- **defs** (*Iterable*[Definition[*A*, *CodeLoc*]])
- **expr** (*Any | None*)

**add_register_use**(*reg_offset*, *size*, *expr=None*)

**Return type**
None

**Parameters**

- **reg_offset** (*int*)
- **size** (*int*)
- **expr** (*Any | None*)

**add_register_use_by_defs**(*defs*, *expr=None*)

**Return type**
None

**Parameters**

- **defs** (*Iterable*[Definition[*A*, *CodeLoc*]])
- **expr** (*Any | None*)

**add_stack_use**(*stack_offset*, *size*, *expr=None*)

**Return type**
None

**Parameters**

- **stack_offset** (*int*)
- **size** (*int*)
- **expr** (*Any | None*)

**add_stack_use_by_defs**(*defs*, *expr=None*)

**Parameters**

- **defs** (*Iterable[Definition[A, CodeLoc]]*)
- **expr** (*Any | None*)

**add_heap_use**(*heap_offset*, *size*, *expr=None*)

**Return type**
None

**Parameters**

- **heap_offset** (*int*)
- **size** (*int*)
- **expr** (*Any | None*)

**add_heap_use_by_defs**(*defs*, *expr=None*)

**Parameters**

- **defs** (*Iterable[Definition[A, CodeLoc]]*)
- **expr** (*Any | None*)

**add_memory_use_by_def**(*definition*, *expr=None*)

**Parameters**

- **definition** (*Definition[A, CodeLoc]*)
- **expr** (*Any | None*)

**add_memory_use_by_defs**(*defs*, *expr=None*)

**Parameters**

- **defs** (*Iterable[Definition[A, CodeLoc]]*)
- **expr** (*Any | None*)

**get_definitions**(*atom*)

**Return type**
set[*Definition*[*Atom*, ]]

**Parameters**
**atom** (*Atom | Definition[Atom, CodeLoc] | Iterable[Atom] | Iterable[Definition[Atom, CodeLoc]] | MultiValues*)

**get_values**(*spec*)

**Return type**
*MultiValues* | None

**Parameters**
**spec** (*A | Definition[A, CodeLoc] | Iterable[A]*)

**get_one_value**(*spec*, *strip_annotations=False*)

**Return type**
BV | None

**Parameters**

- **spec** (*A | Definition[A, CodeLoc] | Iterable[A] | Iterable[Definition[A, CodeLoc]]*)
- **strip_annotations** (*bool*)

**get_concrete_value**(*spec*, *cast_to=<class 'int'>*)

**Overloads**

- **spec** (Union[*Atom*, *Definition*[*Atom*, ], Iterable[*Atom*]]), **cast_to** (type[int]) → int | None
- **spec** (Union[*Atom*, *Definition*[*Atom*, ], Iterable[*Atom*]]), **cast_to** (type[bytes]) → bytes | None

**Parameters**

- **spec** (*Atom | Definition[Atom, CodeLoc] | Iterable[Atom]*)
- **cast_to** (*type[int | bytes]*)

**Return type**
int | *bytes* | None

**mark_guard**(*target*)

**mark_const**(*value*, *size*)

**Parameters**

- **value** (*int*)
- **size** (*int*)

**downsize**()

**deref**(*pointer*, *size*, *endness=Endness.BE*)

**Overloads**

- **pointer** (int | BV | *HeapAddress* | *SpOffset*), **size** (int | *DerefSize*), **endness** (Endness) = ... → *MemoryLocation* | None
- **pointer** (Union[*MultiValues*, , *Definition*, Iterable[], Iterable[*Definition*[, ]]]), **size** (int | *DerefSize*), **endness** (Endness) = ... → set[*MemoryLocation*]

**Parameters**

- **pointer** (*MultiValues | Atom | Definition[Atom, CodeLoc] | Iterable[Atom] | Iterable[Definition[Atom, CodeLoc]] | int | BV | HeapAddress | SpOffset*)
- **size** (*int | DerefSize*)
- **endness** (*Endness*)

### angr.analyses.reaching_definitions.reaching_definitions

**class** angr.analyses.reaching_definitions.reaching_definitions.**ReachingDefinitionsAnalysis**

Bases: *ForwardAnalysis*[*ReachingDefinitionsState*, , object, object, object], *Analysis*

ReachingDefinitionsAnalysis is a text-book implementation of a static data-flow analysis that works on either a function or a block. It supports both VEX and AIL. By registering observers to observation points, users may use this analysis to generate use-def chains, def-use chains, and reaching definitions, and perform other traditional data-flow analyses such as liveness analysis.

- I've always wanted to find a better name for this analysis. Now I gave up and decided to live with this name for the foreseeable future (until a better name is proposed by someone else).
- Aliasing is definitely a problem, and I forgot how aliasing is resolved in this implementation. I'll leave this as a post-graduation TODO.
- Some more documentation and examples would be nice.

**__init__**(*subject*, *func_graph=None*, *max_iterations=30*, *track_tmps=False*, *track_consts=True*, *observation_points=None*, *init_state=None*, *init_context=None*, *state_initializer=None*, *cc=None*, *function_handler=None*, *observe_all=False*, *visited_blocks=None*, *dep_graph=True*, *observe_callback=None*, *canonical_size=8*, *stack_pointer_tracker=None*, *use_callee_saved_regs_at_return=True*, *interfunction_level=0*, *track_liveness=True*, *func_addr=None*, *element_limit=5*, *merge_into_tops=True*, *variable_map=None*, *flavor=None*)

**Parameters**

- **subject** (*Subject* | Block | *Block* | *Function* | str) – The subject of the analysis: a function, or a single basic block
- **func_graph** – Alternative graph for function.graph.
- **max_iterations** – The maximum number of iterations before the analysis is terminated.
- **track_tmps** – Whether or not temporary variables should be taken into consideration during the analysis.
- **observation_points** (Iterable[tuple[Literal['insn', 'node', 'stmt', 'exit'], int | tuple[int, int] | tuple[int, int, int], *ObservationPointType*]] | None) – A collection of tuples of ("node"|"insn", ins_addr, OP_TYPE) defining where reaching definitions should be copied and stored. OP_TYPE can be OP_BEFORE or OP_AFTER.
- **init_state** (*ReachingDefinitionsState* | None) – An optional initialization state. The analysis creates and works on a copy. Default to None: the analysis then initialize its own abstract state, based on the given <Subject>.
- **init_context** – If init_state is not given, this is used to initialize the context field of the initial state's CodeLocation. The only default-supported type which may go here is a tuple of integers, i.e. a callstack. Anything else requires a custom FunctionHandler.
- **cc** – Calling convention of the function.
- **function_handler** (*FunctionHandler* | None) – The function handler to update the analysis state and results on function calls.
- **observe_all** – Observe every statement, both before and after.
- **visited_blocks** – A set of previously visited blocks.
- **dep_graph** (*DepGraph* | bool | None) – An initial dependency graph to add the result of the analysis to. Set it to None to skip dependency graph generation.

- **canonical_size** – The sizes (in bytes) that objects with an UNKNOWN_SIZE are treated as for operations where sizes are necessary.
- **dep_graph** – Set this to True to generate a dependency graph for the subject. It will be available as *result.dep_graph*.
- **interfunction_level** (int) – The number of functions we should recurse into. This parameter is only used if function_handler is not provided.
- **track_liveness** (bool) – Whether to track liveness information. This can consume sizeable amounts of RAM on large functions. (e.g. ~15GB for a function with 4k nodes)
- **merge_into_tops** (bool) – Merge known values into TOP if TOP is present. If True: {TOP} V {0xabc} = {TOP} If False: {TOP} V {0xabc} = {TOP, 0xabc}
- **flavor** (str | None) – The decompilation flavor whose prototypes of the function and its callees are used (None: the default flavor).
- **state_initializer** (*RDAStateInitializer | None*)
- **func_addr** (*int | None*)
- **element_limit** (*int*)

**property observed_results: dict[tuple[str, int, int], *LiveDefinitions*]**

**property all_definitions**

**property all_uses**

**property one_result**

**property dep_graph: *DepGraph***

**property visited_blocks**

**get_reaching_definitions_by_insn**(*ins_addr*, *op_type*)

**get_reaching_definitions_by_node**(*node_addr*, *op_type*)

**node_observe**(*node_addr*, *state*, *op_type*, *node_idx=None*)

**Parameters**

- **node_addr** (int) – Address of the node.
- **state** (*ReachingDefinitionsState*) – The analysis state.
- **op_type** (*ObservationPointType*) – Type of the observation point. Must be one of the following: OP_BEFORE, OP_AFTER.
- **node_idx** (int | None) – ID of the node. Used in AIL to differentiate blocks with the same address.

**Return type**
None

**insn_observe**(*insn_addr*, *stmt*, *block*, *state*, *op_type*)

**Parameters**

- **insn_addr** (int) – Address of the instruction.
- **stmt** (*Statement* | IRStmt) – The statement.
- **block** (*Block* | Block) – The current block.

- **state** (*ReachingDefinitionsState*) – The abstract analysis state.
- **op_type** (*ObservationPointType*) – Type of the observation point. Must be one of the following: OP_BEORE, OP_AFTER.

**Return type**
None

**stmt_observe**(*stmt_idx*, *stmt*, *block*, *state*, *op_type*)

**Parameters**

- **stmt_idx** (int)
- **stmt** (*Statement* | IRStmt)
- **block** (*Block* | Block)
- **state** (*ReachingDefinitionsState*)
- **op_type** (*ObservationPointType*)

**Return type**
None

**Returns**

**exit_observe**(*node_addr*, *exit_stmt_idx*, *block*, *state*, *node_idx=None*)

**Parameters**

- **node_addr** (*int*)
- **exit_stmt_idx** (*int*)
- **block** (Block | *Block*)
- **state** (ReachingDefinitionsState)
- **node_idx** (*int* | *None*)

**property subject**

**callsites_to**(*target*)

**Return type**
Iterable[*FunctionCallRelationships*]

**Parameters**
**target** (*int* | *str* | Function)

### angr.analyses.reaching_definitions.subject

**class** angr.analyses.reaching_definitions.subject.**SubjectType**

Bases: Enum

**Function = 1**

**Block = 2**

**CallTrace = 3**

**class** angr.analyses.reaching_definitions.subject.**Subject**

Bases: object

**__init__**(*content*, *func_graph=None*, *cc=None*)

The thing being analysed, and the way (visitor) to analyse it.

**Parameters**

- **content** (*Union[ailment.Block, angr.Block, Function]*) – Thing to be analysed.
- **func_graph** (*networkx.DiGraph*) – Alternative graph for function.graph.
- **cc** (SimCC) – Calling convention of the function.

**property cc**

**property content**

**property func_graph**

**property type**

**property visitor: *FunctionGraphVisitor* | *SingleNodeGraphVisitor***

### 10.3.41 angr.analyses.reassembler

**exception** angr.analyses.reassembler.**BinaryError**

Bases: Exception

**exception** angr.analyses.reassembler.**InstructionError**

Bases: *BinaryError*

**exception** angr.analyses.reassembler.**ReassemblerFailureNotice**

Bases: *BinaryError*

angr.analyses.reassembler.**string_escape**(*s*)

angr.analyses.reassembler.**fill_reg_map**()

angr.analyses.reassembler.**split_operands**(*s*)

angr.analyses.reassembler.**is_hex**(*s*)

**class** angr.analyses.reassembler.**Label**

Bases: object

**g_label_ctr = count(0)**

**__init__**(*binary*, *name*, *original_addr=None*)

**property operand_str**

**property offset**

**static new_label**(*binary*, *name=None*, *function_name=None*, *original_addr=None*, *data_label=False*)

**class** angr.analyses.reassembler.**DataLabel**

Bases: *Label*

**__init__**(*binary*, *original_addr*, *name=None*)

**property operand_str**

class angr.analyses.reassembler.**FunctionLabel**

Bases: *Label*

**__init__**(*binary*, *function_name*, *original_addr*, *plt=False*)

**property function_name**

**property operand_str**

class angr.analyses.reassembler.**ObjectLabel**

Bases: *Label*

**__init__**(*binary*, *symbol_name*, *original_addr*, *plt=False*)

**property symbol_name**

**property operand_str**

class angr.analyses.reassembler.**NotypeLabel**

Bases: *Label*

**__init__**(*binary*, *symbol_name*, *original_addr*, *plt=False*)

**property symbol_name**

**property operand_str**

class angr.analyses.reassembler.**SymbolManager**

Bases: object

SymbolManager manages all symbols in the binary.

**__init__**(*binary*, *cfg*)

Constructor.

**Parameters**

- **binary** (Reassembler) – The Binary analysis instance.
- **cfg** (*angr.analyses.CFG*) – The CFG analysis instance.

**Returns**

None

**get_unique_symbol_name**(*symbol_name*)

**new_label**(*addr*, *name=None*, *is_function=None*, *force=False*)

**label_got**(*addr*, *label*)

Mark a certain label as assigned (to an instruction or a block of data).

**Parameters**

- **addr** (*int*) – The address of the label.
- **label** (angr.analyses.reassembler.Label) – The label that is just assigned.

**Returns**

None

class angr.analyses.reassembler.**Operand**

Bases: object

**__init__**(*binary*, *insn_addr*, *insn_size*, *capstone_operand*, *operand_str*, *mnemonic*, *operand_offset*, *syntax=None*)

Constructor.

**Parameters**

- **binary** (Reassembler) – The Binary analysis.
- **insn_addr** (*int*) – Address of the instruction.
- **capstone_operand**
- **operand_str** (*str*) – the string representation of this operand
- **mnemonic** (*str*) – Mnemonic of the instruction that this operand belongs to.
- **operand_offset** (*int*) – offset of the operand into the instruction.
- **syntax** (*str*) – Provide a way to override the default syntax coming from *binary*.

**Returns**
None

**assembly**()

**property is_immediate**

**property symbolized**

**class** angr.analyses.reassembler.**Instruction**

Bases: object

High-level representation of an instruction in the binary

**__init__**(*binary*, *addr*, *size*, *insn_bytes*, *capstone_instr*)

**Parameters**

- **binary** (Reassembler) – The Binary analysis
- **addr** (*int*) – Address of the instruction
- **size** (*int*) – Size of the instruction
- **insn_bytes** (*str*) – Instruction bytes
- **capstone_instr** – Capstone Instr object.

**Returns**
None

**assign_labels**()

**dbg_comments**()

**assembly**(*comments=False*, *symbolized=True*)

**Returns**

**class** angr.analyses.reassembler.**BasicBlock**

Bases: object

BasicBlock represents a basic block in the binary.

**__init__**(*binary*, *addr*, *size*, *x86_getpc_retsite=False*)

Constructor.

**Parameters**

- **binary** (Reassembler) – The Binary analysis.
- **addr** (*int*) – Address of the block
- **size** (*int*) – Size of the block
- **x86_getpc_retsite** (*bool*)

**Returns**
None

**assign_labels**()

**assembly**(*comments=False*, *symbolized=True*)

**instruction_addresses**()

**class** angr.analyses.reassembler.**Procedure**

Bases: object

Procedure in the binary.

**__init__**(*binary*, *function=None*, *addr=None*, *size=None*, *name=None*, *section='.text'*, *asm_code=None*)

Constructor.

**Parameters**

- **binary** (Reassembler) – The Binary analysis.
- **function** (*angr.knowledge.Function*) – The function it represents
- **addr** (*int*) – Address of the function. Not required if *function* is provided.
- **size** (*int*) – Size of the function. Not required if *function* is provided.
- **section** (*str*) – Which section this function comes from.

**Returns**
None

**property name**

Get function name from the labels of the very first block. :return: Function name if there is any, None otherwise :rtype: string

**property is_plt**

If this function is a PLT entry or not. :return: True if this function is a PLT entry, False otherwise :rtype: bool

**assign_labels**()

**assembly**(*comments=False*, *symbolized=True*)

Get the assembly manifest of the procedure.

**Parameters**

- **comments**
- **symbolized**

**Returns**
A list of tuples (address, basic block assembly), ordered by basic block addresses

**Return type**
list

`instruction_addresses()`

Get all instruction addresses in the binary.

**Returns**
A list of sorted instruction addresses.

**Return type**
list

`class angr.analyses.reassembler.ProcedureChunk`

Bases: *Procedure*

Procedure chunk.

`__init__(project, addr, size)`

Constructor.

**Parameters**

- **project**
- **addr**
- **size**

**Returns**

`class angr.analyses.reassembler.Data`

Bases: object

`__init__(binary, memory_data=None, section=None, section_name=None, name=None, size=None, sort=None, addr=None, initial_content=None)`

`property content`

`shrink(new_size)`

Reduce the size of this block

**Parameters**
**new_size** (*int*) – The new size

**Returns**
None

`desymbolize()`

We believe this was a pointer and symbolized it before. Now we want to desymbolize it.

The following actions are performed: - Reload content from memory - Mark the sort as 'unknown'

**Returns**
None

`assign_labels()`

`assembly(comments=False, symbolized=True)`

class angr.analyses.reassembler.**Relocation**

Bases: object

**__init__**(*addr*, *ref_addr*, *sort*)

class angr.analyses.reassembler.**Reassembler**

Bases: *Analysis*

High-level representation of a binary with a linear representation of all instructions and data regions. After calling "symbolize", it essentially acts as a binary reassembler.

Tested on CGC, x86 and x86-64 binaries.

Disclaimer: The reassembler is an empirical solution. Don't be surprised if it does not work on some binaries.

**__init__**(*syntax='intel'*, *remove_cgc_attachments=True*, *log_relocations=True*)

**property instructions**

Get a list of all instructions in the binary

**Returns**
A list of (address, instruction)

**Return type**
tuple

**property relocations**

**property inserted_asm_before_label**

**property inserted_asm_after_label**

**property main_executable_regions**

return:

**property main_nonexecutable_regions**

return:

**disassemble_block**(*block*)

Disassemble a block using the assembly syntax configured for this Reassembler.

When AT&T syntax is requested, a capstone instance dedicated to this analysis is used, so that neither the project-wide Arch object nor the capstone instance cached on it is modified.

**Parameters**
**block** – The angr Block to disassemble.

**Returns**
A CapstoneBlock instance.

**Return type**
*CapstoneBlock*

**section_alignment**(*section_name*)

Get the alignment for the specific section. If the section is not found, 16 is used as default.

**Parameters**
**section_name** (*str*) – The section.

**Returns**
The alignment in bytes.

**Return type**
int

`main_executable_regions_contain`(*addr*)

**Parameters**
**addr**

**Returns**

`main_executable_region_limbos_contain`(*addr*)

Sometimes there exists a pointer that points to a few bytes before the beginning of a section, or a few bytes after the beginning of the section. We take care of that here.

**Parameters**
**addr** (*int*) – The address to check.

**Returns**
A 2-tuple of (bool, the closest base address)

**Return type**
tuple

`main_nonexecutable_regions_contain`(*addr*)

**Parameters**
**addr** (*int*) – The address to check.

**Returns**
True if the address is inside a non-executable region, False otherwise.

**Return type**
bool

`main_nonexecutable_region_limbos_contain`(*addr*, *tolerance_before=64*, *tolerance_after=64*)

Sometimes there exists a pointer that points to a few bytes before the beginning of a section, or a few bytes after the beginning of the section. We take care of that here.

**Parameters**
**addr** (*int*) – The address to check.

**Returns**
A 2-tuple of (bool, the closest base address)

**Return type**
tuple

`register_instruction_reference`(*insn_addr*, *ref_addr*, *sort*, *operand_offset*)

`register_data_reference`(*data_addr*, *ref_addr*)

`add_label`(*name*, *addr*)

Add a new label to the symbol manager.

**Parameters**

- **name** (*str*) – Name of the label.
- **addr** (*int*) – Address of the label.

**Returns**
None

**insert_asm**(*addr*, *asm_code*, *before_label=False*)

Insert some assembly code at the specific address. There must be an instruction starting at that address.

**Parameters**

- **addr** (*int*) – Address of insertion
- **asm_code** (*str*) – The assembly code to insert

**Returns**
None

**append_procedure**(*name*, *asm_code*)

Add a new procedure with specific name and assembly code.

**Parameters**

- **name** (*str*) – The name of the new procedure.
- **asm_code** (*str*) – The assembly code of the procedure

**Returns**
None

**append_data**(*name*, *initial_content*, *size*, *readonly=False*, *sort='unknown'*)

Append a new data entry into the binary with specific name, content, and size.

**Parameters**

- **name** (*str*) – Name of the data entry. Will be used as the label.
- **initial_content** (bytes) – The initial content of the data entry.
- **size** (*int*) – Size of the data entry.
- **readonly** (*bool*) – If the data entry belongs to the readonly region.
- **sort** (*str*) – Type of the data.

**Returns**
None

**remove_instruction**(*ins_addr*)

**Parameters**
**ins_addr**

**Returns**

**randomize_procedures**()

**Returns**

**symbolize**()

**assembly**(*comments=False*, *symbolized=True*)

**remove_cgc_attachments**()

Remove CGC attachments.

**Returns**
True if CGC attachments are found and removed, False otherwise

**Return type**
bool

**remove_unnecessary_stuff**()

Remove unnecessary functions and data

**Returns**
None

**remove_unnecessary_stuff_glibc**()

**fast_memory_load**(*addr*, *size*, *data_type*, *endness='Iend_LE'*)

Load memory bytes from loader's memory backend.

**Parameters**

- **addr** (*int*) – The address to begin memory loading.
- **size** (*int*) – Size in bytes.
- **data_type** – Type of the data.
- **endness** (*str*) – Endianness of this memory load.

**Returns**
Data read out of the memory.

**Return type**
int or *bytes* or str or None

### 10.3.42 angr.analyses.s_liveness

**class** angr.analyses.s_liveness.**SLivenessModel**

Bases: object

The SLiveness model that stores LiveIn and LiveOut sets for each block in a partial-SSA function.

Blocks are identified by address and (block) index.

**__init__**()

**class** angr.analyses.s_liveness.**SLivenessAnalysis**

Bases: *Analysis*

Calculates LiveIn and LiveOut sets for each block in a partial-SSA function.

**__init__**(*func*, *func_graph*, *entry=None*, *func_addr=None*, *arg_vvars=None*)

**Parameters**

- **func** (Function)
- **func_graph** (*networkx.DiGraph[Block]*)
- **entry** (Block | *None*)
- **func_addr** (*int* | *None*)
- **arg_vvars** (*list[VirtualVariable]* | *None*)

**interference_graph**(*vvar_ids=None*)

Generate an interference graph based on the liveness analysis result.

**Parameters**
**vvar_ids** (set[int] | None) – When given, only keep edges whose both endpoints are in this set. The full graph is quadratic in the number of live vvars, so restrict it to the vvars whose interference the caller will actually query.

**Return type**
networkx.Graph[int]

**Returns**
A networkx.Graph instance.

`live_vars_by_stmt()`

Get a mapping from statements to live variables at the point of the statement.

**Return type**
`defaultdict`[, `dict`[`int`, *`VVarSet`*]]

**Returns**
A dictionary mapping statements to sets of live variable IDs.

### 10.3.43 angr.analyses.s_propagator

`angr.analyses.s_propagator.sprop_cache_scope(cache)`

Install `cache` as the active AILBlockWalker cache for the current thread.

**Parameters**
**cache** (*`dict[tuple[type, ...], AILWhitelistExprTypeWalker]`*)

**class** `angr.analyses.s_propagator.SPropagatorModel`

Bases: `object`

The SPropagator model that stores replacements for virtual variables.

`__init__()`

**class** `angr.analyses.s_propagator.SPropagator`

Bases: `object`

Constant and expression propagation that only supports SSA AIL graphs.

Deliberately not an `Analysis` for better speed.

`__init__(project, subject, *, ail_manager, func_graph=None, only_consts=True, stack_pointer_tracker=None, func_args=None, func_addr=None, stack_arg_offsets=None)`

**Parameters**

- **project** (`Project`)
- **subject** (`Block` | `Function`)
- **ail_manager** (*`Manager`*)
- **func_graph** (*`networkx.DiGraph` | `None`*)
- **only_consts** (*`bool`*)
- **func_args** (*`set[VirtualVariable]` | `None`*)
- **func_addr** (*`int` | `None`*)
- **stack_arg_offsets** (*`set[int]` | `None`*)

`property replacements`

`property dead_vvar_ids`

**static is_global_variable_updated**(*func_graph*, *block_dict*, *varid*, *gv_addr*, *gv_size*, *defloc*, *useloc*)

**Return type**
bool

**Parameters**

- **varid** (*int*)
- **gv_addr** (*int*)
- **gv_size** (*int*)
- **defloc** (AILCodeLocation)
- **useloc** (AILCodeLocation)

**static is_vvar_used_for_addr_loading_switch_case**(*uselocs*, *blocks*)

Check if a virtual variable is used for loading an address in a switch-case construct.

**Parameters**

- **uselocs** (set[*AILCodeLocation*]) – The use locations of the virtual variable.
- **blocks** – All blocks of the current function.

**Return type**
bool

**Returns**
True if the virtual variable is used for loading an address in a switch-case construct, False otherwise.

**static replace**(*replacements*, *loc*, *expr*, *value*)

**Return type**
None

**Parameters**

- **replacements** (*dict*[AILCodeLocation, *dict*[VirtualVariable | Tmp, Expression]])
- **loc** (AILCodeLocation)
- **expr** (VirtualVariable | Tmp)
- **value** (Expression)

**class** angr.analyses.s_propagator.**SPropagatorAnalysis**

Bases: *Analysis*, *SPropagator*

A wrapper around SPropagator to make it an Analysis.

**__init__**(**args*, ***kwargs*)

### 10.3.44 angr.analyses.s_reaching_definitions

**class** angr.analyses.s_reaching_definitions.**SRDAModel**

Bases: object

The model for SRDA.

**__init__**(*func_graph*, *func_args*, *arch*, *platform=None*, *language=None*, *variable_map=None*, *functions=None*, *default_cc=None*)

**Parameters**

- **platform** (*str | None*)
- **language** (*str | None*)
- **functions** (FunctionManager | *None*)
- **default_cc** (type[SimCC] | *None*)

**add_vvar_use**(*vvar_id*, *expr*, *loc*)

**Return type**
None

**Parameters**

- **vvar_id** (*int*)
- **expr** (VirtualVariable | *None*)
- **loc** (AILCodeLocation)

**add_vvar_def**(*vvar_id*, *loc*)

Record the definition of a vvar id, keeping all_vvar_definitions and vvar_defs_by_loc in sync.

**Return type**
None

**Parameters**

- **vvar_id** (*int*)
- **loc** (AILCodeLocation)

**remove_vvar_def**(*vvar_id*)

Drop the definition of a vvar id from both all_vvar_definitions and vvar_defs_by_loc.

**Return type**
None

**Parameters**
**vvar_id** (*int*)

**update_after_block_edits**(*edited_blocks*)

Incrementally update the model after the statements of `edited_blocks` were edited *in place* (statement indices preserved, e.g. by replacing removed statements with `NoOp` placeholders). vvar definitions and explicit vvar uses inside the edited blocks are recomputed from the edited blocks; implicit uses (`expr is None`, e.g. call-site argument registers) and all unedited blocks are left untouched.

This is designed to be equivalent to a full SRDA rebuild on the edited graph for the kind of edits performed by dead-assignment removal: statements are only removed (turned into NoOp) or rewritten in place, never inserted or reordered, and removed vvars are dead (so they are never used elsewhere, including by phi nodes or implicit call-site uses). Tmp tracking is not updated (AILSimplifier does not track tmps).

**Return type**
None

**canonical_form**()

An order-insensitive snapshot of the model's vvar-keyed data, for asserting equivalence between an incrementally-updated model and a freshly-rebuilt one (used by the incremental-update verification harness).

**property all_definitions: Iterator[*Definition*[*VirtualVariable*, *AILCodeLocation*]]**

**get_definition_by_varid**(*varid*)

The definition of a vvar id, or None if it has none.

**Return type**
Optional[*Definition*[*VirtualVariable*, *AILCodeLocation*]]

**Parameters**
**varid** (*int*)

**is_phi_vvar_id**(*idx*)

**Return type**
bool

**Parameters**
**idx** (*int*)

**get_all_definitions**(*block_loc*)

**Return type**
set[*Definition*[*VirtualVariable* | *Tmp*, *AILCodeLocation*]]

**Parameters**
**block_loc** (AILCodeLocation)

**get_all_tmp_definitions**(*block_loc*)

**Return type**
set[*Definition*[*Tmp*, *AILCodeLocation*]]

**Parameters**
**block_loc** (*Address*)

**get_uses_by_location**(*loc*, *exprs=False*)

Retrieve all definitions that are used at a given location.

**Overloads**

- **loc** (), **exprs** (Literal[True]) → set[tuple[*Definition*[*VirtualVariable*, *AILCodeLocation*], Any | None]]
- **loc** (), **exprs** (Literal[False]) = ... → set[*Definition*[*VirtualVariable*, *AILCodeLocation*]]

**Parameters**

- **loc** (*AILCodeLocation*) – The code location.
- **exprs** (*bool*)

**Returns**
A set of definitions that are used at the given location.

**Return type**
set[Definition[VirtualVariable, AILCodeLocation]] | set[tuple[Definition[VirtualVariable, AILCodeLocation], *Any* | None]]

**get_defs_by_location**(*loc*)

Retrieve all vvar definitions at a given location.

**Parameters**
**loc** (*AILCodeLocation*) – The code location.

**Return type**
set[*Definition*[*VirtualVariable*, *AILCodeLocation*]]

**Returns**
A set of definitions that are defined at the given location.

**get_vvar_uses**(*obj*)

**Return type**
set[*AILCodeLocation*]

**Parameters**
**obj** (VirtualVariable | VirtualVariable)

**get_vvar_uses_with_expr**(*obj*)

**Return type**
set[tuple[*VirtualVariable* | None, *AILCodeLocation*]]

**Parameters**
**obj** (VirtualVariable | VirtualVariable)

**get_tmp_uses**(*obj*, *block_loc*)

**Return type**
set[*AILCodeLocation*]

**Parameters**

- **obj** (Tmp)
- **block_loc** (*Address*)

**get_uses_by_def**(*def_*)

**Return type**
set[*AILCodeLocation*]

**Parameters**
**def_** (Definition[VirtualVariable | Tmp, AILCodeLocation])

**class** angr.analyses.s_reaching_definitions.**SRDAView**

Bases: object

A view of SRDA model that provides various functionalities for querying the model.

**__init__**(*model*)

**Parameters**
**model** (SRDAModel)

**get_reg_vvar_by_stmt**(*reg_offset*, *min_size*, *block_addr*, *block_idx*, *stmt_idx*, *op_type*)

**Return type**
*VirtualVariable* | None

**Parameters**

- **reg_offset** (*int*)

- **min_size** (*int*)
- **block_addr** (*int*)
- **block_idx** (*int*)
- **stmt_idx** (*int*)
- **op_type** (ObservationPointType)

**get_stack_vvar_by_stmt**(*stack_offset*, *size*, *block_addr*, *block_idx*, *stmt_idx*, *op_type*)

**Return type**
*VirtualVariable* | None

**Parameters**

- **stack_offset** (*int*)
- **size** (*int*)
- **block_addr** (*int*)
- **block_idx** (*int*)
- **stmt_idx** (*int*)
- **op_type** (ObservationPointType)

**get_reg_vvar_by_insn**(*reg_offset*, *min_size*, *addr*, *op_type*, *block_idx=0*)

**Return type**
*VirtualVariable* | None

**Parameters**

- **reg_offset** (*int*)
- **min_size** (*int*)
- **addr** (*int*)
- **op_type** (ObservationPointType)
- **block_idx** (*int*)

**get_stack_vvar_by_insn**(*stack_offset*, *size*, *addr*, *op_type*, *block_idx=0*)

**Return type**
*VirtualVariable* | None

**Parameters**

- **stack_offset** (*int*)
- **size** (*int*)
- **addr** (*int*)
- **op_type** (ObservationPointType)
- **block_idx** (*int*)

**get_vvar_value**(*vvar*)

**Return type**
*Expression* | None

**Parameters**
**vvar** (VirtualVariable)

**observe**(*observation_points*, *entry=None*)

**Parameters**

- **observation_points** (*list[tuple[Literal['insn', 'node', 'stmt', 'exit'], int | tuple[int, int] | tuple[int, int, int], ~angr.knowledge_plugins.key_definitions.constants.ObservationPointType]]*)
- **entry** (*Block | None*)

**class** angr.analyses.s_reaching_definitions.**SReachingDefinitions**

Bases: object

Constant and expression propagation that only supports SSA AIL graphs.

Deliberately not an Analysis: it is instantiated hundreds of times per decompilation (often once per block), so it skips the analysis-factory ceremony. Instantiate it directly with the project as the first argument; exceptions always propagate.

**__init__**(*project*, *subject*, *func_addr=None*, *func_graph=None*, *func_args=None*, *use_callee_saved_regs_at_return=False*, *track_tmps=False*, *variable_map=None*)

**Parameters**

- **project** (Project)
- **func_addr** (*int | None*)
- **func_graph** (*networkx.DiGraph[Block] | None*)
- **func_args** (*set[VirtualVariable] | None*)
- **use_callee_saved_regs_at_return** (*bool*)
- **track_tmps** (*bool*)

**class** angr.analyses.s_reaching_definitions.**SReachingDefinitionsAnalysis**

Bases: *Analysis*, *SReachingDefinitions*

A wrapper around SReachingDefinitions to make it usable as an Analysis and registered in the analysis hub.

**__init__**(*subject*, *func_addr=None*, *func_graph=None*, *func_args=None*, *use_callee_saved_regs_at_return=False*, *track_tmps=False*, *variable_map=None*)

**Parameters**

- **func_addr** (*int | None*)
- **func_graph** (*networkx.DiGraph[Block] | None*)
- **func_args** (*set[VirtualVariable] | None*)
- **use_callee_saved_regs_at_return** (*bool*)
- **track_tmps** (*bool*)

angr.analyses.s_reaching_definitions.**populate_model**(*model*, *blocks*, *func_args*, ***, *fix_undefined_vvars=True*, *track_tmps=False*)

Populate the scan-derived part of an SRDAModel (vvar/tmp definitions and uses, phi bookkeeping) with a linear scan over blocks. An SRDAModel is never serialized; it is always rebuilt from an AIL graph through this function (via SReachingDefinitions or directly).

**Return type**
None

**Parameters**

- **model** (SRDAModel)
- **blocks** (*dict[tuple[int, int], Block]*)
- **func_args** (*set[VirtualVariable] | None*)
- **fix_undefined_vvars** (*bool*)
- **track_tmps** (*bool*)

### angr.analyses.s_reaching_definitions.s_rda_model

**class** angr.analyses.s_reaching_definitions.s_rda_model.**SRDAModel**

Bases: object

The model for SRDA.

**__init__**(*func_graph*, *func_args*, *arch*, *platform=None*, *language=None*, *variable_map=None*, *functions=None*, *default_cc=None*)

**Parameters**

- **platform** (*str | None*)
- **language** (*str | None*)
- **functions** (FunctionManager | *None*)
- **default_cc** (type[SimCC] | *None*)

**add_vvar_use**(*vvar_id*, *expr*, *loc*)

**Return type**
None

**Parameters**

- **vvar_id** (*int*)
- **expr** (VirtualVariable | *None*)
- **loc** (AILCodeLocation)

**add_vvar_def**(*vvar_id*, *loc*)

Record the definition of a vvar id, keeping all_vvar_definitions and vvar_defs_by_loc in sync.

**Return type**
None

**Parameters**

- **vvar_id** (*int*)

- **loc** (AILCodeLocation)

**remove_vvar_def**(*vvar_id*)

Drop the definition of a vvar id from both all_vvar_definitions and vvar_defs_by_loc.

**Return type**
None

**Parameters**
**vvar_id** (*int*)

**update_after_block_edits**(*edited_blocks*)

Incrementally update the model after the statements of `edited_blocks` were edited *in place* (statement indices preserved, e.g. by replacing removed statements with `NoOp` placeholders). vvar definitions and explicit vvar uses inside the edited blocks are recomputed from the edited blocks; implicit uses (`expr is None`, e.g. call-site argument registers) and all unedited blocks are left untouched.

This is designed to be equivalent to a full SRDA rebuild on the edited graph for the kind of edits performed by dead-assignment removal: statements are only removed (turned into NoOp) or rewritten in place, never inserted or reordered, and removed vvars are dead (so they are never used elsewhere, including by phi nodes or implicit call-site uses). Tmp tracking is not updated (AILSimplifier does not track tmps).

**Return type**
None

**canonical_form**()

An order-insensitive snapshot of the model's vvar-keyed data, for asserting equivalence between an incrementally-updated model and a freshly-rebuilt one (used by the incremental-update verification harness).

**property all_definitions:** Iterator[*Definition*[*VirtualVariable*, *AILCodeLocation*]]

**get_definition_by_varid**(*varid*)

The definition of a vvar id, or None if it has none.

**Return type**
Optional[*Definition*[*VirtualVariable*, *AILCodeLocation*]]

**Parameters**
**varid** (*int*)

**is_phi_vvar_id**(*idx*)

**Return type**
bool

**Parameters**
**idx** (*int*)

**get_all_definitions**(*block_loc*)

**Return type**
set[*Definition*[*VirtualVariable* | *Tmp*, *AILCodeLocation*]]

**Parameters**
**block_loc** (AILCodeLocation)

**get_all_tmp_definitions**(*block_loc*)

**Return type**
set[*Definition*[*Tmp*, *AILCodeLocation*]]

**Parameters**
**block_loc** (*Address*)

**get_uses_by_location**(*loc*, *exprs=False*)

Retrieve all definitions that are used at a given location.

**Overloads**

- **loc** (), **exprs** (Literal[True]) → set[tuple[*Definition*[*VirtualVariable*, *AILCodeLocation*], Any | None]]
- **loc** (), **exprs** (Literal[False]) = ... → set[*Definition*[*VirtualVariable*, *AILCodeLocation*]]

**Parameters**

- **loc** (*AILCodeLocation*) – The code location.
- **exprs** (*bool*)

**Returns**
A set of definitions that are used at the given location.

**Return type**
set[Definition[VirtualVariable, AILCodeLocation]] | set[tuple[Definition[VirtualVariable, AILCodeLocation], *Any* | None]]

**get_defs_by_location**(*loc*)

Retrieve all vvar definitions at a given location.

**Parameters**
**loc** (*AILCodeLocation*) – The code location.

**Return type**
set[*Definition*[*VirtualVariable*, *AILCodeLocation*]]

**Returns**
A set of definitions that are defined at the given location.

**get_vvar_uses**(*obj*)

**Return type**
set[*AILCodeLocation*]

**Parameters**
**obj** (VirtualVariable | VirtualVariable)

**get_vvar_uses_with_expr**(*obj*)

**Return type**
set[tuple[*VirtualVariable* | None, *AILCodeLocation*]]

**Parameters**
**obj** (VirtualVariable | VirtualVariable)

**get_tmp_uses**(*obj*, *block_loc*)

**Return type**
set[*AILCodeLocation*]

**Parameters**

- **obj** (Tmp)
- **block_loc** (*Address*)

**get_uses_by_def**(*def_*)

**Return type**
set[*AILCodeLocation*]

**Parameters**
**def_** (Definition[VirtualVariable | Tmp, AILCodeLocation])

angr.analyses.s_reaching_definitions.s_rda_model.**populate_model**(*model*, *blocks*, *func_args*, ***, *fix_undefined_vvars=True*, *track_tmps=False*)

Populate the scan-derived part of an SRDAModel (vvar/tmp definitions and uses, phi bookkeeping) with a linear scan over `blocks`. An SRDAModel is never serialized; it is always rebuilt from an AIL graph through this function (via `SReachingDefinitions` or directly).

**Return type**
None

**Parameters**

- **model** (SRDAModel)
- **blocks** (*dict[tuple[int, int], Block]*)
- **func_args** (*set[VirtualVariable] | None*)
- **fix_undefined_vvars** (*bool*)
- **track_tmps** (*bool*)

### angr.analyses.s_reaching_definitions.s_rda_view

angr.analyses.s_reaching_definitions.s_rda_view.**get_call_clobbered_regs**(*call*, *variable_map*, *functions*, *arch*, *platform*, *language*, *default_cc_cls=None*)

**Return type**
set[int]

**Parameters**

- **call** (Call)
- **functions** (FunctionManager | *None*)
- **platform** (*str* | *None*)
- **language** (*str* | *None*)
- **default_cc_cls** (type[SimCC] | *None*)

**class** angr.analyses.s_reaching_definitions.s_rda_view.**RegVVarPredicate**

Bases: object

Implements a predicate that is used in get_reg_vvar_by_stmt_idx and get_reg_vvar_by_insn.

**__init__**(*reg_offset*, *min_size*, *vvars*, *arch*, *platform=None*, *language=None*, *variable_map=None*, *functions=None*, *default_cc_cls=None*)

**Parameters**

- **reg_offset** (*int*)

- **min_size** (*int*)
- **vvars** (*list[VirtualVariable]*)
- **platform** (*str | None*)
- **language** (*str | None*)
- **functions** (*FunctionManager | None*)
- **default_cc_cls** (*type[SimCC] | None*)

**predicate**(*stmt*)

**Return type**
bool

**Parameters**
**stmt** (*Statement*)

class angr.analyses.s_reaching_definitions.s_rda_view.**StackVVarPredicate**

Bases: object

Implements a predicate that is used in get_stack_vvar_by_stmt_idx and get_stack_vvar_by_insn.

**__init__**(*stack_offset*, *size*, *vvars*)

**Parameters**

- **stack_offset** (*int*)
- **size** (*int*)
- **vvars** (*list[VirtualVariable]*)

**predicate**(*stmt*)

**Return type**
bool

**Parameters**
**stmt** (*Statement*)

class angr.analyses.s_reaching_definitions.s_rda_view.**SRDAView**

Bases: object

A view of SRDA model that provides various functionalities for querying the model.

**__init__**(*model*)

**Parameters**
**model** (*SRDAModel*)

**get_reg_vvar_by_stmt**(*reg_offset*, *min_size*, *block_addr*, *block_idx*, *stmt_idx*, *op_type*)

**Return type**
*VirtualVariable* | None

**Parameters**

- **reg_offset** (*int*)
- **min_size** (*int*)
- **block_addr** (*int*)
- **block_idx** (*int*)

- **stmt_idx** (*int*)
- **op_type** (ObservationPointType)

**get_stack_vvar_by_stmt**(*stack_offset*, *size*, *block_addr*, *block_idx*, *stmt_idx*, *op_type*)

**Return type**
*VirtualVariable* | None

**Parameters**

- **stack_offset** (*int*)
- **size** (*int*)
- **block_addr** (*int*)
- **block_idx** (*int*)
- **stmt_idx** (*int*)
- **op_type** (ObservationPointType)

**get_reg_vvar_by_insn**(*reg_offset*, *min_size*, *addr*, *op_type*, *block_idx=0*)

**Return type**
*VirtualVariable* | None

**Parameters**

- **reg_offset** (*int*)
- **min_size** (*int*)
- **addr** (*int*)
- **op_type** (ObservationPointType)
- **block_idx** (*int*)

**get_stack_vvar_by_insn**(*stack_offset*, *size*, *addr*, *op_type*, *block_idx=0*)

**Return type**
*VirtualVariable* | None

**Parameters**

- **stack_offset** (*int*)
- **size** (*int*)
- **addr** (*int*)
- **op_type** (ObservationPointType)
- **block_idx** (*int*)

**get_vvar_value**(*vvar*)

**Return type**
*Expression* | None

**Parameters**
**vvar** (VirtualVariable)

**observe**(*observation_points*, *entry=None*)

**Parameters**

- **observation_points** (*list[tuple[Literal['insn', 'node', 'stmt', 'exit'], int | tuple[int, int] | tuple[int, int, int], ~angr.knowledge_plugins.key_definitions.constants.ObservationPointType]]*)
- **entry** (*Block | None*)

### angr.analyses.s_reaching_definitions.s_reaching_definitions

**class** angr.analyses.s_reaching_definitions.s_reaching_definitions.**SReachingDefinitions**

Bases: object

Constant and expression propagation that only supports SSA AIL graphs.

Deliberately not an Analysis: it is instantiated hundreds of times per decompilation (often once per block), so it skips the analysis-factory ceremony. Instantiate it directly with the project as the first argument; exceptions always propagate.

**__init__**(*project*, *subject*, *func_addr=None*, *func_graph=None*, *func_args=None*, *use_callee_saved_regs_at_return=False*, *track_tmps=False*, *variable_map=None*)

**Parameters**

- **project** (Project)
- **func_addr** (*int | None*)
- **func_graph** (*networkx.DiGraph[Block] | None*)
- **func_args** (*set[VirtualVariable] | None*)
- **use_callee_saved_regs_at_return** (*bool*)
- **track_tmps** (*bool*)

**class** angr.analyses.s_reaching_definitions.s_reaching_definitions.**SReachingDefinitionsAnalysis**

Bases: *Analysis*, *SReachingDefinitions*

A wrapper around SReachingDefinitions to make it usable as an Analysis and registered in the analysis hub.

**__init__**(*subject*, *func_addr=None*, *func_graph=None*, *func_args=None*, *use_callee_saved_regs_at_return=False*, *track_tmps=False*, *variable_map=None*)

**Parameters**

- **func_addr** (*int | None*)
- **func_graph** (*networkx.DiGraph[Block] | None*)
- **func_args** (*set[VirtualVariable] | None*)
- **use_callee_saved_regs_at_return** (*bool*)
- **track_tmps** (*bool*)

### 10.3.45 angr.analyses.smc

**class** angr.analyses.smc.**TraceActions**

Bases: IntFlag

Describe memory access actions.

**WRITE = 1**

**EXECUTE = 2**

**__new__**(*value*)

**class** angr.analyses.smc.**TraceClassifier**

Bases: object

Classify traces.

**__init__**(*state=None*)

**Parameters**
**state** (SimState | *None*)

**act_mem_write**(*state*)

SimInspect callback for memory writes.

**Return type**
None

**act_instruction**(*state*)

SimInspect callback for instruction execution.

**Return type**
None

**instrument**(*state*)

Instrument *state* for tracing.

**Return type**
None

**get_smc_address_and_lengths**()

Evaluate the trace to find which areas of memory were both written to and executed.

**Return type**
Generator[tuple[int, int]]

**determine_smc**()

Evaluate the trace to find areas of memory that were both written to and executed.

**Return type**
bool

**pp**()

**class** angr.analyses.smc.**SelfModifyingCodeAnalysis**

Bases: *Analysis*

Determine if some piece of code is self-modifying.

This determination is made by simply executing. If an address is executed that is also written to, the code is determined to be self-modifying. The determination is stored in the *result* property. The *regions* property contains a list of (addr, length) regions that were both written to and executed.

**__init__**(*subject*, *max_bytes=0*, *state=None*)

**Parameters**

- **subject** (int | str | *Function* | None) – Subject of analysis
- **max_bytes** (int) – Maximum number of bytes from subject address. 0 for no limit (default).
- **state** (*SimState* | None) – State to begin executing from.

**regions:** list[tuple[int, int]]

**result:** bool

### 10.3.46 angr.analyses.soot_class_hierarchy

**exception** angr.analyses.soot_class_hierarchy.**SootClassHierarchyError**

Bases: Exception

**exception** angr.analyses.soot_class_hierarchy.**NoConcreteDispatch**

Bases: *SootClassHierarchyError*

**class** angr.analyses.soot_class_hierarchy.**SootClassHierarchy**

Bases: *Analysis*

Generate complete hierarchy.

**__init__**()

**init_hierarchy**()

**has_super_class**(*cls*)

**is_subclass_including**(*cls_child*, *cls_parent*)

**is_subclass**(*cls_child*, *cls_parent*)

**is_visible_method**(*cls*, *method*)

**is_visible_class**(*cls_from*, *cls_to*)

**get_super_classes**(*cls*)

**get_super_classes_including**(*cls*)

**get_implementers**(*interface*)

**get_sub_interfaces_including**(*interface*)

**get_sub_interfaces**(*interface*)

**get_sub_classes**(*cls*)

**get_sub_classes_including**(*cls*)

**resolve_abstract_dispatch**(*cls*, *method*)

**resolve_concrete_dispatch**(*cls*, *method*)

**resolve_special_dispatch**(*method*, *container*)

**resolve_invoke**(*invoke_expr*, *method*, *container*)

### 10.3.47 angr.analyses.stack_pointer_tracker

**class** angr.analyses.stack_pointer_tracker.**BottomType**

Bases: object

The bottom value for register values.

**class** angr.analyses.stack_pointer_tracker.**Constant**

Bases: object

Represents a constant value.

**__init__**(*val*)

**val**

**class** angr.analyses.stack_pointer_tracker.**Register**

Bases: object

Represent a register.

**__init__**(*offset*, *bitlen*)

**offset**

**bitlen**

**class** angr.analyses.stack_pointer_tracker.**OffsetVal**

Bases: object

Represent a value with an offset added.

**__init__**(*reg*, *offset*)

**property reg**

**property offset**

**class** angr.analyses.stack_pointer_tracker.**Eq**

Bases: object

Represent an equivalence condition.

**__init__**(*val0*, *val1*)

**val0**

**val1**

**class** angr.analyses.stack_pointer_tracker.**FrozenStackPointerTrackerState**

Bases: object

Abstract state for StackPointerTracker analysis with registers and memory values being in frozensets.

**__init__**(*regs*, *memory*, *is_tracking_memory*, *resilient*)

**regs**

**memory**

**is_tracking_memory**

**resilient**

**unfreeze**()

**merge**(*other*, *addr*, *reg_merge_cache*, *mem_merge_cache*)

**Parameters**

- **addr** (*int*)
- **reg_merge_cache** (*dict[tuple[int, int], Any]*)
- **mem_merge_cache** (*dict[tuple[int, int], Any]*)

**class** angr.analyses.stack_pointer_tracker.**StackPointerTrackerState**

Bases: object

Abstract state for StackPointerTracker analysis.

**__init__**(*regs*, *memory*, *is_tracking_memory*, *resilient*)

**Parameters**
**resilient** (*bool*)

**regs**

**memory**

**is_tracking_memory**

**resilient**

**give_up_on_memory_tracking**()

**store**(*addr*, *val*)

**pop_dirty**()

**load**(*addr*)

**get**(*reg*)

**put**(*reg*, *val*, *force=False*)

**Parameters**
**force** (*bool*)

**copy**()

**freeze**()

**merge**(*other*, *addr*, *reg_merge_cache*, *mem_merge_cache*)

**Parameters**

- **addr** (*int*)
- **reg_merge_cache** (*dict[tuple[int, int], Any]*)
- **mem_merge_cache** (*dict[tuple[int, int], Any]*)

**exception** angr.analyses.stack_pointer_tracker.**CouldNotResolveException**

Bases: Exception

An exception used in StackPointerTracker analysis to represent internal resolving failures.

**class** angr.analyses.stack_pointer_tracker.**StackPointerTracker**

Bases: *Analysis*, *ForwardAnalysis*

Track the offset of stack pointer at the end of each basic block of a function.

**__init__**(*func*, *reg_offsets*, *block=None*, *track_memory=True*, *cross_insn_opt=True*, *initial_reg_values=None*, *resilient=True*, *cross_insn_opt_callback=None*, *flavor=None*)

**Parameters**

- **flavor** (str | None) – The decompilation flavor whose callee and call-site prototypes are consulted (None: the default flavor).
- **func** (*Function | None*)
- **reg_offsets** (*set[int]*)
- **block** (*Block | None*)
- **resilient** (*bool*)
- **cross_insn_opt_callback** (*Callable[[int, int], bool] | None*)

**reg_values:** dict[int, dict[int, Any]]

**mem_values:** dict[int, dict[int, Any]]

**reg_deltas:** dict[int, dict[int, dict[int, Any]]]

**mem_deltas:** dict[int, dict[int, dict[int, Any]]]

**offset_after**(*addr*, *reg*)

**offset_before**(*addr*, *reg*)

**offset_after_block**(*block_addr*, *reg*)

**offset_before_block**(*block_addr*, *reg*)

**constant_after**(*addr*, *reg*)

**constant_before**(*addr*, *reg*)

**constant_after_block**(*block_addr*, *reg*)

**constant_before_block**(*block_addr*, *reg*)

**property inconsistent**

**inconsistent_for**(*reg*)

**offsets_for**(*reg*)

**callee_cleanup_size_at**(*node*)

The number of bytes this analysis assumes the callee pops at the call site ending node.

**Return type**
int

### 10.3.48 angr.analyses.static_hooker

**class** angr.analyses.static_hooker.**StaticHooker**

Bases: *Analysis*

This analysis works on statically linked binaries - it finds the library functions statically linked into the binary and hooks them with the appropriate simprocedures.

Right now it only works on unstripped binaries, but hey! There's room to grow!

**__init__**(*library*, *binary=None*)

### 10.3.49 angr.analyses.typehoon

**class** angr.analyses.typehoon.**TypeTranslator**

Bases: object

Translate type constants to SimType and SimType to type constants.

**__init__**(*arch*, *func_addr=None*)

**Parameters**

- **arch** (*archinfo.Arch*)
- **func_addr** (*int | None*)

**arch:** Arch

**func_addr:** int | None

**translated:** dict[*TypeConstant*, *SimType*]

**translated_simtypes:** dict[*SimType*, *TypeConstant*]

**structs**

**memo:** dict[str, *Struct*]

**named_struct_id_counter**

**struct_name_to_idx**

**known_structs:** dict[str, *SimStruct*]

**struct_name**()

Create a name for an auto-generated struct. Do not conflict with struct names in self.known_structs.

**Return type**
str

**tc2simtype**(*tc*)

**simtype2tc**(*simtype*)

**Return type**
*TypeConstant*

**Parameters**
**simtype** (SimType)

**lift**(*simtype*)

**Return type**
*TypeConstant*

**Parameters**
**simtype** (SimType)

**concretize**(*tc*)

**backpatch**(*st*, *translated*)

**Parameters**

- **st** (sim_type.SimType)
- **translated** (*dict*)

**Returns**

**class** angr.analyses.typehoon.**Typehoon**

Bases: *Analysis*

A spiritual tribute to the long-standing typehoon project that @jmg (John Grosen) worked on during his days in the angr team. Now I feel really bad of asking the poor guy to work directly on VEX IR without any fancy static analysis support as we have right now...

Typehoon analysis implements a pushdown system that simplifies and solves type constraints. Our type constraints are largely an implementation of the paper Polymorphic Type Inference for Machine Code by Noonan, Loginov, and Cok from GrammaTech (with missing functionality support and bugs, of course). Type constraints are collected by running VariableRecoveryFast (maybe VariableRecovery later as well) on a function, and then solved using this analysis.

User may specify ground truth, which will override all types at certain program points during constraint solving.

**__init__**(*constraints*, *func_var*, *ground_truth=None*, *var_mapping=None*, *must_struct=None*, *stackvar_max_sizes=None*, *stack_offset_tvs=None*, *constraint_set_degradation_threshold=150*, *type_translator=None*, *tv_manager=None*)

**Parameters**

- **constraints**
- **ground_truth** – A set of SimType-style solutions for some or all type variables. They will be respected during type solving.
- **var_mapping** (dict[*SimVariable*, set[*TypeVariable*]] | None)
- **must_struct** (set[*TypeVariable*] | None)
- **stackvar_max_sizes** (*dict[TypeVariable, int] | None*)
- **stack_offset_tvs** (*dict[int, TypeVariable] | None*)
- **constraint_set_degradation_threshold** (*int*)
- **type_translator** (*TypeTranslator | None*)
- **tv_manager** (*TypeVariableManager | None*)

**update_variable_types**(*func_addr*, *var_to_typevars*, *stack_offset_tvs=None*, *flavor=None*)

**Parameters**

- **flavor** (str | None) – The decompilation flavor whose global manager receives the types when func_addr is "global".

- **func_addr** (*int | str*)
- **var_to_typevars** (*dict[SimVariable, set[TypeVariable]]*)
- **stack_offset_tvs** (*dict[int, TypeVariable] | None*)

**Return type**
None

**pp_constraints**()

Pretty-print constraints between *variables* using the variable mapping.

**Return type**
None

**pp_solution**()

Pretty-print solutions using the variable mapping.

**Return type**
None

## Submodules

| | |
|---|---|
| *dfa* | |

| *typehoon* | |
| *typevars* | |
| *variance* | |

### angr.analyses.typehoon.dfa

**exception** angr.analyses.typehoon.dfa.**EmptyEpsilonNFAError**

Bases: *AngrError*

A notification exception generated when the epsilon NFA is empty.

**class** angr.analyses.typehoon.dfa.**DFAConstraintSolver**

Bases: object

Implements a DFA-based graph solver.

**static graph_to_epsilon_nfa**(*graph*, *starts*, *ends*)

**Return type**
EpsilonNFA

**Parameters**

- **graph** (*DiGraph*)
- **starts** (*set*)
- **ends** (*set*)

**generate_constraints_between**(*graph*, *starts*, *ends*)

**Return type**
set

**Parameters**

- **graph** (*DiGraph*)
- **starts** (*set*)
- **ends** (*set*)

### angr.analyses.typehoon.simple_solver

**class** angr.analyses.typehoon.simple_solver.**TypeLattice**

Bases: object

A lattice of type constants with a lowest-common-ancestor table for caching purposes.

The lattice graph (*self.g*) should be treated as read-only, otherwise the cached LCA table will be invalidated once the lattice graph changes.

**__init__**(*g*)

**Parameters**
**g** (*DiGraph*)

**g: DiGraph**

**inverted**()

Return a new lattice with every edge reversed, i.e. ordered from the most specific to the most general.

**Return type**
*TypeLattice*

**lca**(*node_a*, *node_b*)

Return the lowest common ancestor of node_a and node_b, or None if they have none. Initialize the LCA table on the first query and memoize it for subsequent queries. This is critical for performance when the lattice is relatively small (< 100 nodes) and the number of queries is large.

Reconsider this implementation when the type lattice is large.

**class** angr.analyses.typehoon.simple_solver.**SketchNodeBase**

Bases: object

The base class for nodes in a sketch.

**class** angr.analyses.typehoon.simple_solver.**SketchNode**

Bases: *SketchNodeBase*

Represents a node in a sketch graph.

**__init__**(*typevar*)

**Parameters**
**typevar** (TypeVariable | DerivedTypeVariable)

**typevar: *TypeVariable* | *DerivedTypeVariable***

**upper_bound: *TypeConstant***

**lower_bound: *TypeConstant***

**property size: int | None**

Best-effort estimation of the size of the typevar (in bits). Returns None if we cannot determine.

class angr.analyses.typehoon.simple_solver.**RecursiveRefNode**

Bases: *SketchNodeBase*

Represents a cycle in a sketch graph.

This is equivalent to sketches.LabelNode in the reference implementation of retypd.

**__init__**(*target*)

**Parameters**
**target** (TypeVariable | DerivedTypeVariable)

**target:** *TypeVariable | DerivedTypeVariable*

class angr.analyses.typehoon.simple_solver.**Sketch**

Bases: object

Describes the sketch of a type variable.

**__init__**(*solver*, *root*)

**Parameters**

- **solver** (SimpleSolver)
- **root** (TypeVariable)

**root:** *SketchNode*

**graph**

**node_mapping:** dict[*TypeVariable | DerivedTypeVariable*, *SketchNodeBase*]

**solver**

**lookup**(*typevar*)

**Return type**
*SketchNodeBase* | None

**Parameters**
**typevar** (TypeVariable | DerivedTypeVariable)

**add_edge**(*src*, *dst*, *label*)

**Return type**
None

**Parameters**

- **src** (SketchNodeBase)
- **dst** (SketchNodeBase)

**add_constraint**(*constraint*)

**Return type**
None

**Parameters**
**constraint** (TypeConstraint)

**static flatten_typevar**(*derived_typevar*)

**Return type**
tuple[*DerivedTypeVariable* | *TypeVariable* | *TypeConstant*, bool]

**Parameters**
**derived_typevar** (TypeVariable | TypeConstant | DerivedTypeVariable)

**class** angr.analyses.typehoon.simple_solver.**ConstraintGraphTag**

Bases: Enum

**__init__**(*n*)

**LEFT = 0**

**RIGHT = 1**

**UNKNOWN = 2**

**class** angr.analyses.typehoon.simple_solver.**FORGOTTEN**

Bases: Enum

**__init__**(*n*)

**PRE_FORGOTTEN = 0**

**POST_FORGOTTEN = 1**

**class** angr.analyses.typehoon.simple_solver.**ConstraintGraphNode**

Bases: object

**__init__**(*typevar*, *variance*, *tag*, *forgotten*)

**Parameters**

- **typevar** (TypeVariable | DerivedTypeVariable | TypeConstant)
- **variance** (Variance)
- **tag** (ConstraintGraphTag)
- **forgotten** (FORGOTTEN)

**typevar**

**variance**

**tag**

**forgotten**

**forget_last_label**()

**Return type**
tuple[*ConstraintGraphNode*, *BaseLabel*] | None

**recall**(*label*)

**Return type**
*ConstraintGraphNode*

**Parameters**
**label** (BaseLabel)

**recall_many**(*new_labels*)

Recall all labels at once. Recalling them one by one builds (and hashes) a DerivedTypeVariable per label, which is quadratic in the length of the label chain.

**Return type**
*ConstraintGraphNode*

**Parameters**
**new_labels** (*Sequence[BaseLabel]*)

**inverse**()

**Return type**
*ConstraintGraphNode*

**inverse_wo_tag**()

Invert the variance only.

**Return type**
*ConstraintGraphNode*

angr.analyses.typehoon.simple_solver.**map_offsets_to_bases**(*candidate_bases*)

Map each candidate field offset to the offset of the lowest field that covers it.

`candidate_bases` maps a field offset to the set of sizes that this field is accessed with; a field at offset `o` covers the bytes in `[o, o + max(sizes))`. Fields may overlap, in which case the lowest one wins.

We only ever need the bases of offsets that are candidate bases themselves, so the covered ranges are compared directly instead of being expanded byte by byte – a single field can be hundreds of megabytes wide.

**Return type**
SortedDict

**Parameters**
**candidate_bases** (*SortedDict*)

**class** angr.analyses.typehoon.simple_solver.**SimpleSolver**

Bases: `object`

SimpleSolver is, by its name, a simple solver. Most of this solver is based on the (complex) simplification logic that the retypd paper describes and the retypd re-implementation (https://github.com/GrammaTech/retypd) implements. Additionally, we add some improvements to allow type propagation of known struct names, among a few other improvements.

**OFFSET_MIRROR_ROUNDS = 4**

**__init__**(*bits*, *constraints*, *typevars*, *constraint_set_degradation_threshold=150*, *stackvar_max_sizes=None*, *tv_manager=None*)

**Parameters**

- **bits** (*int*)
- **typevars** (*dict[TypeVariable, set[TypeVariable]]*)
- **constraint_set_degradation_threshold** (*int*)
- **stackvar_max_sizes** (*dict[TypeVariable, int] | None*)
- **tv_manager** (*TypeVariableManager | None*)

**processed_constraints_count: int**

**simplified_constraints_count:** int

**eqclass_constraints_count:** list[int]

**get_tv_max_stack_size**(*tv*)

Get the potential maximum stack variable size of a given type variable, if any. Also considers other type variables that are equivalent to the given type variable.

**Return type**
int | None

**Parameters**
**tv** (TypeVariable)

**preprocess**(*func_tv*)

**Parameters**
**func_tv** (TypeVariable)

**solve**()

Steps:

For each type variable, - Infer the shape in its sketch - Build the constraint graph - Collect all constraints - Apply constraints to derive the lower and upper bounds - Determine a solution for type variables with constraints - Rewrite the constraint graph by replacing determined type variables with their solutions - Solve repeatedly until all interesting type variables have solutions

By repeatedly solving until exhausting interesting type variables, we ensure the S-Trans rule is applied.

**infer_shapes**(*typevars*, *constraints*)

Computing sketches from constraint sets. Implements Algorithm E.1 in the retypd paper.

**Return type**
tuple[dict, dict[*TypeVariable*, *Sketch*]]

**Parameters**

- **typevars** (*set[TypeVariable]*)
- **constraints** (*set[TypeConstraint]*)

**compute_quotient_graph**(*constraints*, *extra_typevars=None*)

Compute the quotient graph (the constraint graph modulo ~ in Algorithm E.1 in the retypd paper) with respect to a given set of type constraints. extra_typevars are the program variables' type variables: an offset term (p.+N) holding a variable belongs in the graph even when no constraint mentions it.

**Parameters**

- **constraints** (*set[TypeConstraint]*)
- **extra_typevars** (*set[TypeVariable] | None*)

**static to_typevar_or_typeconst**(*obj*)

**Return type**
*TypeVariable* | *TypeConstant*

**Parameters**
**obj** (TypeVariable | DerivedTypeVariable | TypeConstant)

**join**(*t1*, *t2*)

**Return type**
*TypeConstant*

**Parameters**

- **t1** (TypeConstant)
- **t2** (TypeConstant)

**meet**(*t1*, *t2*)

**Return type**
*TypeConstant*

**Parameters**

- **t1** (TypeConstant)
- **t2** (TypeConstant)

**classmethod join_simtypes**(*t1*, *t2*, *arch*)

Compute the join (the least general common supertype) of two SimTypes on the type lattice.

The two types are lifted to internal type constants, joined on the base lattice for `arch.bits`, and the result is translated back into a SimType. When the two types have no meaningful common supertype, the result is a `SimTypeBottom`.

**Parameters**

- **t1** (*SimType*) – The first SimType.
- **t2** (*SimType*) – The second SimType.
- **arch** (Arch) – The architecture, used to determine the pointer size and to build the resulting SimType.

**Return type**
*SimType*

**Returns**
The join of `t1` and `t2` as a SimType.

**classmethod meet_simtypes**(*t1*, *t2*, *arch*)

Compute the meet (the greatest common subtype) of two SimTypes on the type lattice.

See *join_simtypes()* for details. When the two types have no meaningful common subtype, the result is a `SimTypeBottom`.

**Return type**
*SimType*

**Parameters**

- **t1** (SimType)
- **t2** (SimType)
- **arch** (*archinfo.Arch*)

**static abstract**(*t*)

**Return type**
*TypeConstant* | *TypeVariable*

**Parameters**
**t** (TypeConstant | TypeVariable)

**determine**(*sketches*, *tvs*, *equivalence_classes*, *solution*, *nodes=None*)

Determine C-like types from sketches.

**Parameters**

- **sketches** – A dictionary storing sketches for each type variable.
- **solution** (dict) – The dictionary storing C-like types for each type variable. Output.
- **nodes** (set[*SketchNode*] | None) – Optional. Nodes that should be considered in the sketch.
- **equivalence_classes** (*dict[TypeVariable, TypeVariable]*)

**Return type**
None

**Returns**
None

**static dump_constraint_graph**(*graph*, *filename*)

Dump the constraint graph to a file.

**Return type**
None

**Parameters**

- **graph** (*DiGraph*)
- **filename** (*str*)

### angr.analyses.typehoon.translator

**class** angr.analyses.typehoon.translator.**SimTypeTempRef**

Bases: *SimType*

Represents a temporary reference to another type. TypeVariableReference is translated to SimTypeTempRef.

**c_repr**(*name=None*, *full=0*, *memo=None*, *indent=0*, *name_parens=True*)

**Return type**
str

**Parameters**

- **indent** (*int | None*)
- **name_parens** (*bool*)

**class** angr.analyses.typehoon.translator.**TypeTranslator**

Bases: object

Translate type constants to SimType and SimType to type constants.

**__init__**(*arch*, *func_addr=None*)

**Parameters**

- **arch** (*archinfo.Arch*)
- **func_addr** (*int | None*)

**arch:** Arch

**func_addr:** int | None

**translated:** dict[*TypeConstant*, *SimType*]

**translated_simtypes:** dict[*SimType*, *TypeConstant*]

**structs**

**memo:** dict[str, *Struct*]

**named_struct_id_counter**

**struct_name_to_idx**

**known_structs:** dict[str, *SimStruct*]

**struct_name**()

Create a name for an auto-generated struct. Do not conflict with struct names in self.known_structs.

**Return type**
str

**tc2simtype**(*tc*)

**simtype2tc**(*simtype*)

**Return type**
*TypeConstant*

**Parameters**
**simtype** (SimType)

**lift**(*simtype*)

**Return type**
*TypeConstant*

**Parameters**
**simtype** (SimType)

**concretize**(*tc*)

**backpatch**(*st*, *translated*)

**Parameters**

- **st** (sim_type.SimType)
- **translated** (*dict*)

**Returns**

### angr.analyses.typehoon.typeconsts

All type constants used in type inference. They can be mapped, translated, or rewritten to C-style types.

angr.analyses.typehoon.typeconsts.**memoize**(*f*)

**class** angr.analyses.typehoon.typeconsts.**TypeConstant**

Bases: object

SIZE = None

TYPE_HASH: int = 1984226046

__init__(*name=None*)

**Parameters**
**name** (*str | None*)

pp_str(*mapping*)

**Return type**
str

property size: int

replace(*mapping*, *memo=None*)

**Return type**
*TypeConstant*

**Parameters**

- **mapping** (*dict[int, TypeConstant]*)
- **memo** (*set[TypeConstant] | None*)

class angr.analyses.typehoon.typeconsts.**TopType**

**Parameters**
**name** (*str | None*)

TYPE_HASH: int = 3659745635

class angr.analyses.typehoon.typeconsts.Pointer64

Bases: *Pointer*, *Int64*

64-bit pointers.

__init__(*basetype=None*, *name=None*)

**Parameters**
**name** (*str | None*)

TYPE_HASH: int = 1312233491

class angr.analyses.typehoon.typeconsts.Array

Bases: TypeConstant

__init__(*element=None*, *count=None*, *name=None*)

**Parameters**
**name** (*str | None*)

element: TypeConstant | None

count: int | None

property size: int

replace(*mapping*, *memo=None*)

**Return type**
*TypeConstant*

**Parameters**

- **mapping** (*dict[int, TypeConstant]*)
- **memo** (*set | None*)

TYPE_HASH: int = 1624097203

class angr.analyses.typehoon.typeconsts.Struct

Bases: TypeConstant

__init__(*fields=None*, *name=None*, *field_names=None*, *is_cppclass=False*, *idx=-1*, *size=None*)

**Parameters**

- **is_cppclass** (*bool*)
- **idx** (*int*)
- **size** (*int | None*)

property fields: dict[int, TypeConstant]

property size: int

TYPE_HASH: int = 3175010840

class angr.analyses.typehoon.typeconsts.EnumVariant

Bases: object

__init__(*name*, *fields*, *discriminant*, *discriminant_size*, *size*)

fields: list[tuple[TypeConstant, str | None]]

class angr.analyses.typehoon.typeconsts.RustEnum

Bases: TypeConstant

__init__(*name=None*, *variants=None*)

get_variant(*name*)

**Return type**
*EnumVariant* | None

property size: int

replace(*mapping*, *memo=None*)

**Return type**
*TypeConstant*

**Parameters**

- **mapping** (*dict[int, TypeConstant]*)
- **memo** (*set | None*)

TYPE_HASH: int = 3260887885

class angr.analyses.typehoon.typeconsts.Enum

Bases: *TypeConstant*

Enum type constant for type inference.

**Variables**

- **members** (dict[str, int]) – Mapping of enum member names to their integer values
- **base_type** – The underlying type constant (defaults to Int32)
- **idx** – Unique identifier for this enum

__init__(*members=None*, *base_type=None*, *name=None*, *idx=-1*)

**Parameters**

- **members** (*dict[str, int] | None*)
- **base_type** (*TypeConstant | None*)
- **name** (*str | None*)
- **idx** (*int*)

members: dict[str, int]

property size: int

Return the size of the enum in bytes.

replace(*mapping*, *memo=None*)

**Return type**
*TypeConstant*

**Parameters**

- **mapping** (*dict[int, TypeConstant]*)
- **memo** (*set | None*)

TYPE_HASH: int = 2928410991

class angr.analyses.typehoon.typeconsts.Function

Bases: *TypeConstant*

__init__(*params*, *outputs*, *name=None*)

**Parameters**

- **params** (*list*)
- **outputs** (*list*)
- **name** (*str | None*)

replace(*mapping*, *memo=None*)

**Return type**
*TypeConstant*

**Parameters**

- **mapping** (*dict[int, TypeConstant]*)
- **memo** (*set | None*)

TYPE_HASH: int = 869823595

class angr.analyses.typehoon.typeconsts.**TypeVariableReference**

Bases: *TypeConstant*

__init__(*typevar*, *name=None*)

**Parameters**
**name** (*str | None*)

TYPE_HASH: int = 3866462522

angr.analyses.typehoon.typeconsts.**int_type**(*bits*)

**Return type**
*Int*

**Parameters**
**bits** (*int*)

angr.analyses.typehoon.typeconsts.**signed_int_type**(*bits*)

**Return type**
*Int*

**Parameters**
**bits** (*int*)

angr.analyses.typehoon.typeconsts.**unsigned_int_type**(*bits*)

**Return type**
*Int*

**Parameters**
**bits** (*int*)

angr.analyses.typehoon.typeconsts.**float_type**(*bits*)

**Return type**
*Float* | None

**Parameters**
**bits** (*int*)

### angr.analyses.typehoon.typehoon

**class** angr.analyses.typehoon.typehoon.**Typehoon**

Bases: *Analysis*

A spiritual tribute to the long-standing typehoon project that @jmg (John Grosen) worked on during his days in the angr team. Now I feel really bad of asking the poor guy to work directly on VEX IR without any fancy static analysis support as we have right now...

Typehoon analysis implements a pushdown system that simplifies and solves type constraints. Our type constraints are largely an implementation of the paper Polymorphic Type Inference for Machine Code by Noonan, Loginov, and Cok from GrammaTech (with missing functionality support and bugs, of course). Type constraints are collected by running VariableRecoveryFast (maybe VariableRecovery later as well) on a function, and then solved using this analysis.

User may specify ground truth, which will override all types at certain program points during constraint solving.

**__init__**(*constraints*, *func_var*, *ground_truth=None*, *var_mapping=None*, *must_struct=None*, *stackvar_max_sizes=None*, *stack_offset_tvs=None*, *constraint_set_degradation_threshold=150*, *type_translator=None*, *tv_manager=None*)

**Parameters**

- **constraints**
- **ground_truth** – A set of SimType-style solutions for some or all type variables. They will be respected during type solving.
- **var_mapping** (dict[*SimVariable*, set[*TypeVariable*]] | None)
- **must_struct** (set[*TypeVariable*] | None)
- **stackvar_max_sizes** (*dict[TypeVariable, int] | None*)
- **stack_offset_tvs** (*dict[int, TypeVariable] | None*)
- **constraint_set_degradation_threshold** (*int*)
- **type_translator** (*TypeTranslator | None*)
- **tv_manager** (*TypeVariableManager | None*)

**update_variable_types**(*func_addr*, *var_to_typevars*, *stack_offset_tvs=None*, *flavor=None*)

**Parameters**

- **flavor** (str | None) – The decompilation flavor whose global manager receives the types when func_addr is "global".
- **func_addr** (*int | str*)
- **var_to_typevars** (*dict[SimVariable, set[TypeVariable]]*)
- **stack_offset_tvs** (*dict[int, TypeVariable] | None*)

**Return type**
None

**pp_constraints**()

Pretty-print constraints between *variables* using the variable mapping.

**Return type**
None

**pp_solution**()

Pretty-print solutions using the variable mapping.

**Return type**
None

### angr.analyses.typehoon.typevars

**class** angr.analyses.typehoon.typevars.**TypeConstraint**

Bases: object

**pp_str**(*mapping*)

**Return type**
str

**Parameters**
**mapping** (*dict[TypeVariable, Any]*)

**class** angr.analyses.typehoon.typevars.**Equivalence**

Bases: *TypeConstraint*

**__init__**(*type_a*, *type_b*)

**type_a**

**type_b**

**pp_str**(*mapping*)

**Return type**
str

**Parameters**
**mapping** (*dict[TypeVariable, Any]*)

**class** angr.analyses.typehoon.typevars.**Existence**

Bases: *TypeConstraint*

**__init__**(*type_*)

**type_**

**pp_str**(*mapping*)

**Return type**
str

**Parameters**
**mapping** (*dict[TypeVariable, Any]*)

**replace**(*replacements*)

**class** angr.analyses.typehoon.typevars.**Subtype**

Bases: *TypeConstraint*

**__init__**(*sub_type*, *super_type*)

**Parameters**

- **sub_type** (*TypeType*)

- **super_type** (*TypeType*)

**super_type**

**sub_type**

**pp_str**(*mapping*)

**Return type**
str

**Parameters**
**mapping** (*dict[TypeVariable, Any]*)

**replace**(*replacements*)

**class** angr.analyses.typehoon.typevars.**Add**

Bases: *TypeConstraint*

Describes the constraint that type_r == type0 + type1

**__init__**(*type_0*, *type_1*, *type_r*)

**type_0**

**type_1**

**type_r**

**pp_str**(*mapping*)

**Return type**
str

**Parameters**
**mapping** (*dict[TypeVariable, Any]*)

**replace**(*replacements*)

**class** angr.analyses.typehoon.typevars.**Sub**

Bases: *TypeConstraint*

Describes the constraint that type_r == type0 - type1

**__init__**(*type_0*, *type_1*, *type_r*)

**type_0**

**type_1**

**type_r**

**pp_str**(*mapping*)

**Return type**
str

**Parameters**
**mapping** (*dict[TypeVariable, Any]*)

**replace**(*replacements*)

class angr.analyses.typehoon.typevars.**TypeVariableManager**

Bases: object

A manager for creating new type variables and derived type variables and keeping track of their indices.

Usually we create a new TypeVariableManager for each function we analyze.

**__init__**(*func_addr*, *idx=0*)

**Parameters**

- **func_addr** (*int*)
- **idx** (*int*)

**next_id**()

**Return type**
int

**property max_tv_id: int**

**new_tv**(*name=None*)

Create a new TypeVariable with a managed ID.

**Return type**
*TypeVariable*

**Parameters**
**name** (*str | None*)

**new_dtv**(*type_var*, ***, *label=None*, *labels=None*)

Create a new DerivedTypeVariable with a managed ID.

**Return type**
*TypeVariable* | *DerivedTypeVariable* | *TypeConstant*

**Parameters**

- **type_var** (TypeVariable | DerivedTypeVariable | TypeConstant)
- **label** (BaseLabel | *None*)
- **labels** (*Sequence[*BaseLabel*]* | *None*)

**new_dtv_with_merged_labels**(*type_var*, ***, *label=None*, *labels=None*)

Create a new DerivedTypeVariable with the given type variable (or DerivedTypeVariable) and labels. Merge the last AddN and SubN labels when possible.

**Return type**
*TypeVariable* | *DerivedTypeVariable* | *TypeConstant*

**Parameters**

- **type_var** (TypeVariable | TypeConstant)
- **label** (BaseLabel | *None*)
- **labels** (*Sequence[*BaseLabel*]* | *None*)

class angr.analyses.typehoon.typevars.**TypeVariable**

Bases: object

__init__(*idx=None*, *name=None*)

**Parameters**

- **idx** (*tuple[int, int] | None*)
- **name** (*str | None*)

**idx:** tuple[int, int]

**name**

**pp_str**(*mapping*)

**Return type**
str

**Parameters**
**mapping** (*dict[TypeVariable, Any]*)

class angr.analyses.typehoon.typevars.**DerivedTypeVariable**

Bases: *TypeVariable*

__init__(*type_var*, *label*, *labels=None*, *idx=None*)

**Parameters**

- **type_var** (TypeVariable | DerivedTypeVariable | TypeConstant)
- **label** (BaseLabel | *None*)
- **labels** (*Iterable[BaseLabel] | None*)
- **idx** (*tuple[int, int] | None*)

**type_var:** *TypeVariable* | *TypeConstant*

**labels:** tuple[*BaseLabel*, ...]

**one_label**()

**Return type**
*BaseLabel* | None

**first_label**()

**Return type**
*BaseLabel*

**path**()

**Return type**
tuple[*BaseLabel*, ...]

**longest_prefix**()

**Return type**
Union[*TypeConstant*, *TypeVariable*, *DerivedTypeVariable*, None]

**pp_str**(*mapping*)

**Return type**
str

**Parameters**
**mapping** (*dict[TypeVariable, Any]*)

**replace**(*replacements*)

class angr.analyses.typehoon.typevars.**TypeVariables**

Bases: object

**__init__**()

**copy**()

**add_type_variable**(*var*, *typevar*, *latest=True*)

**Parameters**

- **var** (SimVariable)
- **typevar** (TypeVariable)
- **latest** (*bool*)

**get_type_variable**(*var*)

**has_type_variable_for**(*var*)

**Parameters**
**var** (SimVariable)

**typevar_to_variable**(*typevar*)

**Return type**
*SimVariable* | None

**Parameters**
**typevar** (TypeVariable)

class angr.analyses.typehoon.typevars.**BaseLabel**

Bases: object

**__init__**()

**property variance:** *Variance*

class angr.analyses.typehoon.typevars.**FuncIn**

Bases: *BaseLabel*

**__init__**(*loc*)

**loc**

class angr.analyses.typehoon.typevars.**FuncOut**

Bases: *BaseLabel*

**__init__**(*loc*)

**loc**

class angr.analyses.typehoon.typevars.**Load**

Bases: *BaseLabel*

class angr.analyses.typehoon.typevars.**Store**

Bases: *BaseLabel*

**property variance:** *Variance*

class angr.analyses.typehoon.typevars.**AddN**

Bases: *BaseLabel*

**__init__**(*n*)

**n**

class angr.analyses.typehoon.typevars.**SubN**

Bases: *BaseLabel*

**__init__**(*n*)

**n**

angr.analyses.typehoon.typevars.**add_label**(*value*, *bits*)

Build the label for `ptr + value`, where `value` is a `bits`-wide constant. The constant is interpreted as signed, so that `ptr + 0xffff_ffff_ffff_ffe8` yields `SubN(24)` instead of `AddN(2 ** 64 - 24)`.

**Return type**
*AddN* | *SubN*

**Parameters**

- **value** (*int*)
- **bits** (*int*)

angr.analyses.typehoon.typevars.**sub_label**(*value*, *bits*)

Build the label for `ptr - value`. See *add_label()*.

**Return type**
*AddN* | *SubN*

**Parameters**

- **value** (*int*)
- **bits** (*int*)

class angr.analyses.typehoon.typevars.**ConvertTo**

Bases: *BaseLabel*

**__init__**(*to_bits*)

**to_bits**

class angr.analyses.typehoon.typevars.**ReinterpretAs**

Bases: *BaseLabel*

**__init__**(*to_type*, *to_bits*)

**to_type**

**to_bits**

class angr.analyses.typehoon.typevars.**HasField**

Bases: *BaseLabel*

Has a field of the given bit size * elem_count at the given offset.

**__init__**(*bits*, *offset*, *elem_count=1*)

**Parameters**
**elem_count** (*int*)

**bits**

**offset**

**elem_count**

class angr.analyses.typehoon.typevars.**IsArray**

Bases: *BaseLabel*

### angr.analyses.typehoon.variance

class angr.analyses.typehoon.variance.**Variance**

Bases: Enum

Enum class describing the variance of type constraints.

**__init__**(*n*)

**COVARIANT = 0**

**CONTRAVARIANT = 1**

## 10.3.50 angr.analyses.unpacker

class angr.analyses.unpacker.**ObfuscationDetector**

Bases: *Analysis*

This analysis detects, usually in ways that are more robust than section name matching or signature matching, the existence of obfuscation techniques in a binary.

**__init__**(*cfg=None*)

**Parameters**
**cfg** (*CFGModel | None*)

**analyze**()

class angr.analyses.unpacker.**PackingDetector**

Bases: *Analysis*

This analysis detects if a binary is likely packed or not. We may extend it to identify which packer is in use in the future.

**PACKED_MIN_BYTES = 256**

**PACKED_ENTROPY_MIN_THRESHOLD = 0.88**

__init__(*cfg=None*, *region_size_threshold=32*)

**Parameters**

- **cfg** (CFGModel | *None*)
- **region_size_threshold** (*int*)

**packed:** bool

**region_size_threshold:** int

**analyze**()

### Submodules

*obfuscation_detector*
*packing_detector*

### angr.analyses.unpacker.obfuscation_detector

**class** angr.analyses.unpacker.obfuscation_detector.**ObfuscationDetector**

Bases: *Analysis*

This analysis detects, usually in ways that are more robust than section name matching or signature matching, the existence of obfuscation techniques in a binary.

__init__(*cfg=None*)

**Parameters**

**cfg** (CFGModel | *None*)

**analyze**()

### angr.analyses.unpacker.packing_detector

**class** angr.analyses.unpacker.packing_detector.**PackingDetector**

Bases: *Analysis*

This analysis detects if a binary is likely packed or not. We may extend it to identify which packer is in use in the future.

**PACKED_MIN_BYTES = 256**

**PACKED_ENTROPY_MIN_THRESHOLD = 0.88**

__init__(*cfg=None*, *region_size_threshold=32*)

**Parameters**

- **cfg** (CFGModel | *None*)
- **region_size_threshold** (*int*)

**packed:** bool

**region_size_threshold:** int

**analyze**()

### 10.3.51 angr.analyses.variable_recovery

**class** angr.analyses.variable_recovery.**VariableRecovery**

Bases: *ForwardAnalysis*, *VariableRecoveryBase*

Recover "variables" from a function using forced execution.

While variables play a very important role in programming, it does not really exist after compiling. However, we can still identify and recovery their counterparts in binaries. It is worth noting that not every variable in source code can be identified in binaries, and not every recognized variable in binaries have a corresponding variable in the original source code. In short, there is no guarantee that the variables we identified/recognized in a binary are the same variables in its source code.

This analysis uses heuristics to identify and recovers the following types of variables: - Register variables. - Stack variables. - Heap variables. (not implemented yet) - Global variables. (not implemented yet)

This analysis takes a function as input, and performs a data-flow analysis on nodes. It runs concrete execution on every statement and hooks all register/memory accesses to discover all places that are accessing variables. It is slow, but has a more accurate analysis result. For a fast but inaccurate variable recovery, you may consider using VariableRecoveryFast.

This analysis follows SSA, which means every write creates a new variable in registers or memory (statck, heap, etc.). Things may get tricky when overlapping variable (in memory, as you cannot really have overlapping accesses to registers) accesses exist, and in such cases, a new variable will be created, and this new variable will overlap with one or more existing variables. A decision procedure (which is pretty much TODO) is required at the end of this analysis to resolve the conflicts between overlapping variables.

**__init__**(*func*, *max_iterations=20*, *store_live_variables=False*)

**Parameters**
**func** (*knowledge.Function*) – The function to analyze.

**class** angr.analyses.variable_recovery.**VariableRecoveryFast**

Bases: *ForwardAnalysis*, *VariableRecoveryBase*

Recover "variables" from a function by keeping track of stack pointer offsets and pattern matching VEX statements.

If calling conventions are recovered prior to running VariableRecoveryFast, variables can be recognized more accurately. However, it is not a requirement. In this case, the function graph you pass must contain information indicating the call-out sites inside the analyzed function. These graph edges must be annotated with either `"type": "call"` or `"outside": True`.

**Parameters**
**flavor** (`str` | `None`) – The decompilation flavor on whose behalf variables are recovered. Only `"rust"` lifts types through the Rust type translator; `None` (the default) recovers C types.

### angr.analyses.variable_recovery.annotations

**class** angr.analyses.variable_recovery.annotations.**StackLocationAnnotation**

Bases: Annotation

**eliminatable = False**

**relocatable = False**

**__init__**(*offset*)

**class** angr.analyses.variable_recovery.annotations.**VariableSourceAnnotation**

Bases: Annotation

**eliminatable = False**

**relocatable = False**

**__init__**(*block_addr*, *stmt_idx*, *ins_addr*)

**static from_state**(*state*)

### angr.analyses.variable_recovery.engine_ail

**class** angr.analyses.variable_recovery.engine_ail.**SimEngineVRAIL**

Bases: *SimEngineNostmtAIL*[VariableRecoveryFastState, *RichR*[BV | FP], None, None], *SimEngineVRBase*[VariableRecoveryFastState, Block]

The engine for variable recovery on AIL.

**__init__**(**args*, *type_lifter*, *call_info=None*, *vvar_to_vvar*, *vvar_type_hints=None*, *func_ret_var=None*, *tv_manager=None*, *variable_map=None*, *flavor=None*, *stack_region_vars=None*, *multi_value_returns=False*, ***kwargs*)

**Parameters**

- **type_lifter** (TypeTranslator)
- **vvar_to_vvar** (*dict[int, int] | None*)
- **vvar_type_hints** (*dict[int, TypeConstant] | None*)
- **func_ret_var** (SimVariable | *None*)
- **tv_manager** (TypeVariableManager | *None*)
- **flavor** (*str | None*)
- **multi_value_returns** (*bool*)

### angr.analyses.variable_recovery.engine_base

**class** angr.analyses.variable_recovery.engine_base.**RichR**

Bases: Generic[]

A rich representation of calculation results. The variable recovery data domain.

**__init__**(*data*, *variable=None*, *typevar=None*, *type_constraints=None*)

**Parameters**

- **data** (*RichRT_co*)

- **typevar** (TypeConstant | TypeVariable | *None*)
- **type_constraints** (*set[TypeConstraint]* | *None*)

**data**

**variable**

**typevar:** *TypeConstant* | *TypeVariable* | None

**type_constraints**

**property bits:** int

**class** angr.analyses.variable_recovery.engine_base.**SimEngineVRBase**

Bases: *SimEngineLight*[VRStateType, *RichR*[BV | FP], BlockType, None], Generic[VRStateType, BlockType]

The base class for variable recovery analyses. Contains methods for basic interactions with the state, like loading and storing data.

**__init__**(*project*, *kb*, *vvar_type_hints=None*, *tv_manager=None*, *stack_region_vars=None*)

**Parameters**

- **vvar_type_hints** (*dict[int, TypeConstant]* | *None*)
- **tv_manager** (TypeVariableManager | *None*)
- **stack_region_vars** (*dict[int, tuple[SimStackVariable, int]]* | *None*)

**vvar_type_hints:** dict[int, *TypeConstant*]

**stack_region_vars:** dict[int, tuple[*SimStackVariable*, int]]

**vvar_region:** dict[int, Any]

**property func_addr**

**property block_idx:** int | None

### angr.analyses.variable_recovery.engine_vex

**class** angr.analyses.variable_recovery.engine_vex.**SimEngineVRVEX**

Bases: *SimEngineNostmtVEX*[VariableRecoveryFastState, *RichR*[BV | FP], None], *SimEngineVRBase*[VariableRecoveryFastState, *Block*]

Implements the VEX engine for variable recovery analysis.

**reg_read_stmts_to_ignore:** set[int]

**stmts_to_lower:** set[int]

**__init__**(**args*, *call_info=None*, ***kwargs*)

### angr.analyses.variable_recovery.irsb_scanner

**class** angr.analyses.variable_recovery.irsb_scanner.**VEXIRSBScanner**

Bases: *SimEngineLightVEX*[None, None, None, None]

Scan the VEX IRSB to determine if any argument-passing registers should be narrowed by detecting cases of loading the whole register and immediately narrowing the register before writing to the tmp.

__init__(*args*, ***kwargs*)

process(*state*, ***, *block=None*, *whitelist=None*, ***kwargs*)

### angr.analyses.variable_recovery.variable_recovery

class angr.analyses.variable_recovery.variable_recovery.**VariableRecoveryState**

Bases: *VariableRecoveryStateBase*

The abstract state of variable recovery analysis.

**Variables**
**variable_manager** (*angr.knowledge.variable_manager.VariableManager*) – The variable manager.

__init__(*project*, *block_addr*, *analysis*, *arch*, *func*, *concrete_states*, ***, *tv_manager*, *stack_region=None*, *register_region=None*)

**Parameters**
- **project** (Project)
- **block_addr** (*int*)
- **arch** (*Arch*)
- **func** (Function)
- **tv_manager** (TypeVariableManager)

property concrete_states

get_concrete_state(*addr*)

**Parameters**
**addr**

**Returns**

copy()

register_callbacks(*concrete_states*)

**Parameters**
**concrete_states**

**Returns**

merge(*others*, *successor=None*)

Merge two abstract states.

**Parameters**
**others** (tuple[*VariableRecoveryState*, ...]) – Other abstract states to merge.

**Returns**
The merged abstract state.

**Return type**
tuple[*VariableRecoveryState*, bool]

class angr.analyses.variable_recovery.variable_recovery.**VariableRecovery**

Bases: *ForwardAnalysis*, *VariableRecoveryBase*

Recover "variables" from a function using forced execution.

While variables play a very important role in programming, it does not really exist after compiling. However, we can still identify and recovery their counterparts in binaries. It is worth noting that not every variable in source code can be identified in binaries, and not every recognized variable in binaries have a corresponding variable in the original source code. In short, there is no guarantee that the variables we identified/recognized in a binary are the same variables in its source code.

This analysis uses heuristics to identify and recovers the following types of variables: - Register variables. - Stack variables. - Heap variables. (not implemented yet) - Global variables. (not implemented yet)

This analysis takes a function as input, and performs a data-flow analysis on nodes. It runs concrete execution on every statement and hooks all register/memory accesses to discover all places that are accessing variables. It is slow, but has a more accurate analysis result. For a fast but inaccurate variable recovery, you may consider using VariableRecoveryFast.

This analysis follows SSA, which means every write creates a new variable in registers or memory (statck, heap, etc.). Things may get tricky when overlapping variable (in memory, as you cannot really have overlapping accesses to registers) accesses exist, and in such cases, a new variable will be created, and this new variable will overlap with one or more existing variables. A decision procedure (which is pretty much TODO) is required at the end of this analysis to resolve the conflicts between overlapping variables.

**__init__**(*func*, *max_iterations=20*, *store_live_variables=False*)

**Parameters**
**func** (*knowledge.Function*) – The function to analyze.

## angr.analyses.variable_recovery.variable_recovery_base

angr.analyses.variable_recovery.variable_recovery_base.**parse_stack_pointer**(*sp*)

Convert multiple supported forms of stack pointer representations into stack offsets.

**Parameters**
**sp** – A stack pointer representation.

**Returns**
A stack pointer offset.

**Return type**
int

class angr.analyses.variable_recovery.variable_recovery_base.**VariableAnnotation**

Bases: Annotation

**relocatable = True**

**eliminatable = False**

**__init__**(*addr_and_variables*)

**Parameters**
**addr_and_variables** (*list[tuple[int, SimVariable]]*)

**addr_and_variables**

class angr.analyses.variable_recovery.variable_recovery_base.**VariableRecoveryBase**

Bases: *Analysis*

The base class for VariableRecovery and VariableRecoveryFast.

**__init__**(*func*, *max_iterations*, *store_live_variables*, *vvar_to_vvar=None*, *func_graph=None*, *entry_node_addr=None*, *flavor=None*)

**Parameters**

- **func** (Function)
- **store_live_variables** (*bool*)
- **vvar_to_vvar** (*dict[int, int] | None*)
- **func_graph** (*networkx.DiGraph[CodeNode] | networkx.DiGraph[ailment.Block] | None*)
- **entry_node_addr** (*int | ailment.Address | None*)
- **flavor** (*str | None*)

**property global_variable_manager:** *VariableManagerInternal*

**get_variable_definitions**(*block_addr*)

Get variables that are defined at the specified block.

**Parameters**
**block_addr** (*int*) – Address of the block.

**Returns**
A set of variables.

**initialize_dominance_frontiers**()

class angr.analyses.variable_recovery.variable_recovery_base.**VariableRecoveryStateBase**

Bases: object

The base abstract state for variable recovery analysis.

**__init__**(*block_addr*, *analysis*, *arch*, *func*, *project*, ***, *tv_manager*, *stack_region=None*, *register_region=None*, *global_region=None*, *typevars=None*, *type_constraints=None*, *func_typevar=None*, *delayed_type_constraints=None*, *stack_offset_typevars=None*)

**Parameters**

- **block_addr** (*int*)
- **analysis** (VariableRecoveryBase)
- **arch** (*archinfo.Arch*)
- **func** (Function)
- **project** (Project)
- **tv_manager** (TypeVariableManager)

**arch:** Arch

**stack_region:** *MultiValuedMemory*

**register_region:** *MultiValuedMemory*

**global_region:** *MultiValuedMemory*

**successor_block_addr:** int | None

**phi_variables:** dict[*SimVariable*, *SimVariable*]

**stack_offset_typevars:** dict[int, *TypeVariable*]

**static top**(*bits*)

**Return type**
BV

**static is_top**(*thing*)

**Return type**
bool

**static extract_variables**(*expr*)

**Return type**
Generator[tuple[int, *SimVariable*]]

**Parameters**
**expr** (*Base*)

**static annotate_with_variables**[*T: Base*](*expr*, *addr_and_variables*)

**Return type**
T

**Parameters**

- **expr** (*T*)
- **addr_and_variables** (*Iterable[tuple[int, SimVariable]]*)

**stack_address**(*offset*)

**Return type**
BV

**Parameters**
**offset** (*int*)

**static is_stack_address**(*addr*)

**Return type**
bool

**Parameters**
**addr** (*Base*)

**is_global_variable_address**(*addr*)

**Return type**
bool

**Parameters**
**addr** (*Bits*)

get_stack_offset(*addr*)

**Return type**
int | None

**Parameters**
**addr** (*Bits*)

stack_addr_from_offset(*offset*)

**Return type**
int

**Parameters**
**offset** (*int*)

property func_addr

property dominance_frontiers

property variable_manager

property global_variable_manager: *VariableManagerInternal*

property variables

get_variable_definitions(*block_addr*)

Get variables that are defined at the specified block.

**Parameters**
**block_addr** (*int*) – Address of the block.

**Returns**
A set of variables.

add_type_constraint(*constraint*)

Add a new type constraint.

**Parameters**
**constraint**

**Returns**

add_type_constraint_for_function(*func_typevar*, *constraint*)

Add a new type constraint for a specified function.

**Parameters**

- **func_typevar**
- **constraint**

**Returns**

downsize()

Remove unnecessary members.

**Return type**
None

**Returns**
None

**static downsize_region**(*region*)

Get rid of unnecessary references in region so that it won't avoid garbage collection on those referenced objects.

**Parameters**
**region** (*MultiValuedMemory*) – A MultiValuedMemory region.

**Return type**
*MultiValuedMemory*

**Returns**
None

### angr.analyses.variable_recovery.variable_recovery_fast

**class** angr.analyses.variable_recovery.variable_recovery_fast.**VariableRecoveryFastState**

Bases: *VariableRecoveryStateBase*

The abstract state of variable recovery analysis.

**Variables**

- **stack_region** (KeyedRegion) – The stack store.
- **register_region** (KeyedRegion) – The register store.

**__init__**(*block_addr*, *analysis*, *arch*, *func*, *project*, *stack_region=None*, *register_region=None*, *global_region=None*, *typevars=None*, *type_constraints=None*, *func_typevar=None*, *delayed_type_constraints=None*, *stack_offset_typevars=None*, *ret_val_size=None*, ***, *tv_manager*)

**Parameters**
**tv_manager** (TypeVariableManager)

**copy**()

**merge**(*others*, *successor=None*)

Merge two abstract states.

For any node A whose dominance frontier that the current node (at the current program location) belongs to, we create a phi variable V' for each variable V that is defined in A, and then replace all existence of V with V' in the merged abstract state.

**Parameters**
**others** (tuple[*VariableRecoveryFastState*, ...]) – Other abstract states to merge.

**Return type**
tuple[*VariableRecoveryFastState*, bool]

**Returns**
The merged abstract state.

**class** angr.analyses.variable_recovery.variable_recovery_fast.**VariableRecoveryFast**

Bases: *ForwardAnalysis*, *VariableRecoveryBase*

Recover "variables" from a function by keeping track of stack pointer offsets and pattern matching VEX statements.

If calling conventions are recovered prior to running VariableRecoveryFast, variables can be recognized more accurately. However, it is not a requirement. In this case, the function graph you pass must contain information indicating the call-out sites inside the analyzed function. These graph edges must be annotated with either `"type": "call"` or `"outside": True`.

**Parameters**

**flavor** (str | None) – The decompilation flavor on whose behalf variables are recovered. Only "rust" lifts types through the Rust type translator; None (the default) recovers C types.

### 10.3.52 angr.analyses.veritesting

**exception** angr.analyses.veritesting.**VeritestingError**

Bases: Exception

**class** angr.analyses.veritesting.**CallTracingFilter**

Bases: object

Filter to apply during CFG creation on a given state and jumpkind to determine if it should be skipped at a certain depth

**whitelist = {<class 'angr.procedures.cgc.receive.receive'>, <class 'angr.procedures.cgc.transmit.transmit'>, <class 'angr.procedures.glibc.__ctype_b_loc.__ctype_b_loc'>, <class 'angr.procedures.libc.atoi.atoi'>, <class 'angr.procedures.libc.fgetc.fgetc'>, <class 'angr.procedures.libc.strcmp.strcmp'>, <class 'angr.procedures.libc.strlen.strlen'>, <class 'angr.procedures.posix.read.read'>}**

**cfg_cache = {}**

**__init__**(*project*, *depth*, *blacklist=None*)

**filter**(*call_target_state*, *jumpkind*)

The call will be skipped if it returns True.

**Parameters**

- **call_target_state** – The new state of the call target.
- **jumpkind** – The Jumpkind of this call.

**Returns**

True if we want to skip this call, False otherwise.

**class** angr.analyses.veritesting.**Veritesting**

Bases: *Analysis*

An exploration technique made for condensing chunks of code to single (nested) if-then-else constraints via CFG accurate to conduct Static Symbolic Execution SSE (conversion to single constraint)

**cfg_cache = {}**

**all_stashes = ('successful', 'errored', 'deadended', 'deviated', 'unconstrained')**

**__init__**(*input_state*, *boundaries=None*, *loop_unrolling_limit=10*, *enable_function_inlining=False*, *terminator=None*, *deviation_filter=None*)

SSE stands for Static Symbolic Execution, and we also implemented an extended version of Veritesting (Avgerinos, Thanassis, et al, ICSE 2014).

**Parameters**

- **input_state** – The initial state to begin the execution with.
- **boundaries** – Addresses where execution should stop.
- **loop_unrolling_limit** – The maximum times that Veritesting should unroll a loop for.

- **enable_function_inlining** – Whether we should enable function inlining and syscall inlining.
- **terminator** – A callback function that takes a state as parameter. Veritesting will terminate if this function returns True.
- **deviation_filter** – A callback function that takes a state as parameter. Veritesting will put the state into "deviated" stash if this function returns True.

**is_not_in_cfg**(*s*)

Returns if s.addr is not a proper node in our CFG.

**Parameters**
**s** (SimState) – The SimState instance to test.

**Returns bool**
False if our CFG contains p.addr, True otherwise.

**is_overbound**(*state*)

Filter out all states that run out of boundaries or loop too many times.

param SimState state: SimState instance to check returns bool: True if outside of mem/loop_ctr boundary

### 10.3.53 angr.analyses.vfg

**class** angr.analyses.vfg.**VFGJob**

Bases: *CFGJobBase*

A job descriptor that contains local variables used during VFG analysis.

**__init__**(**args*, ***kwargs*)

**Return type**
None

**call_stack_suffix:** list

**vfg_node:** *VFGNode* | None

**sim_successors:** *SimSuccessors* | None

**call_function_key:** *FunctionKey* | None

**call_task:** *CallAnalysis* | None

**property block_id:** *BlockID* | None

**callstack_repr**(*kb*)

**Parameters**
**kb** (KnowledgeBase)

**class** angr.analyses.vfg.**PendingJob**

Bases: object

Describes a pending job during VFG analysis.

**__init__**(*block_id*, *state*, *call_stack*, *src_block_id*, *src_stmt_idx*, *src_ins_addr*)

**Parameters**

- **block_id** (BlockID)

- **state** (SimState)
- **call_stack** (CallStack)
- **src_block_id** (BlockID)
- **src_stmt_idx** (*int*)
- **src_ins_addr** (*int*)

**Return type**
None

**block_id**

**state**

**call_stack**

**src_block_id**

**src_stmt_idx**

**src_ins_addr**

class angr.analyses.vfg.**AnalysisTask**

Bases: object

An analysis task describes a task that should be done before popping this task out of the task stack and discard it.

**__init__**()

**Return type**
None

**property done**

class angr.analyses.vfg.**FunctionAnalysis**

Bases: *AnalysisTask*

Analyze a function, generate fix-point states from all endpoints of that function, and then merge them to one state.

**__init__**(*function_address*, *return_address*)

**Parameters**

- **function_address** (*int*)
- **return_address** (*int | None*)

**Return type**
None

**call_analysis:** *AnalysisTask* | None

**property done:** bool

class angr.analyses.vfg.**CallAnalysis**

Bases: *AnalysisTask*

Analyze a call by analyze all functions this call might be calling, collect all final states generated by analyzing those functions, and merge them into one state.

__init__(*address*, *return_address*, *function_analysis_tasks=None*, *mergeable_plugins=None*)

**Parameters**

- **address** (*int*)
- **return_address** (*None*)
- **function_analysis_tasks** (*list[Any] | None*)
- **mergeable_plugins** (*tuple[str, str] | None*)

**Return type**
None

**property done: bool**

**register_function_analysis**(*task*)

**Return type**
None

**Parameters**
**task** (FunctionAnalysis)

**add_final_job**(*job*)

**Return type**
None

**Parameters**
**job** (VFGJob)

**merge_jobs**()

**Return type**
*VFGJob*

**class** angr.analyses.vfg.**VFGNode**

Bases: object

A descriptor of nodes in a Value-Flow Graph

__init__(*addr*, *key*, *state=None*)

Constructor.

**Parameters**

- **addr** (int)
- **key** (*BlockID*)
- **state** (*SimState* | None)

**Return type**
None

**widened_state: *SimState* | None**

**narrowing_times: int**

**all_states: list[*SimState*]**

**events: list**

**input_variables:** list

**actions:** list

**final_states:** list[*SimState*]

**state:** *SimState* | None

**append_state**(*s*, *is_widened_state=False*)

Appended a new state to this VFGNode. :type s: :param s: The new state to append :type is_widened_state: :param is_widened_state: Whether it is a widened state or not.

class angr.analyses.vfg.**VFG**

Bases: *ForwardAnalysis*[*SimState*, *VFGNode*, *VFGJob*, *BlockID*, *SimState*], *Analysis*

This class represents a control-flow graph with static analysis result.

Perform abstract interpretation analysis starting from the given function address. The output is an invariant at the beginning (or the end) of each basic block.

Steps:

- Generate a CFG first if CFG is not provided.
- Identify all merge points (denote the set of merge points as Pw) in the CFG.
- Cut those loop back edges (can be derived from Pw) so that we gain an acyclic CFG.
- **Identify all variables that are 1) from memory loading 2) from initial values, or 3) phi functions. Denote**
  the set of those variables as S_{var}.
- **Start real AI analysis and try to compute a fix point of each merge point. Perform widening/narrowing only on**
  variables in S_{var}.

**__init__**(*cfg=None*, *context_sensitivity_level=2*, *start=None*, *function_start=None*, *interfunction_level=0*, *initial_state=None*, *avoid_runs=None*, *remove_options=None*, *timeout=None*, *max_iterations_before_widening=8*, *max_iterations=40*, *widening_interval=3*, *final_state_callback=None*, *status_callback=None*, *record_function_final_states=False*)

**Parameters**

- **cfg** (*CFGEmulated* | None) – The control-flow graph to base this analysis on. If none is provided, we will construct a CFGEmulated.
- **context_sensitivity_level** (int) – The level of context-sensitivity of this VFG. It ranges from 0 to infinity. Default 2.
- **function_start** (int | None) – The address of the function to analyze.
- **interfunction_level** (int) – The level of interfunction-ness to be
- **initial_state** (*SimState* | None) – A state to use as the initial one
- **avoid_runs** (list[int] | None) – A list of runs to avoid
- **remove_options** (set[str] | None) – State options to remove from the initial state. It only works when *initial_state* is None
- **timeout** (int | None)
- **final_state_callback** (Callable[[*SimState*, *CallStack*], Any] | None) – callback function when countering final state

- **status_callback** (Callable[[*VFG*], Any] | None) – callback function used in _analysis_core_baremetal
- **start** (*int* | *None*)
- **max_iterations_before_widening** (*int*)
- **max_iterations** (*int*)
- **widening_interval** (*int*)
- **record_function_final_states** (*bool*)

**Return type**
None

**final_states: list[*SimState*]**

**property function_initial_states**

**property function_final_states**

**get_any_node**(*addr*)

Get any VFG node corresponding to the basic block at @addr. Note that depending on the context sensitivity level, there might be multiple nodes corresponding to different contexts. This function will return the first one it encounters, which might not be what you want.

**Return type**
*VFGNode* | None

**Parameters**
**addr** (*int*)

**get_all_nodes**(*addr*)

**Return type**
Generator[*VFGNode*]

**irsb_from_node**(*node*)

**copy**()

**MAX_NARROWING_ROUNDS = 2**

### 10.3.54 angr.analyses.vsa_ddg

**class** angr.analyses.vsa_ddg.**DefUseChain**

Bases: object

Stand for a def-use chain. it is generated by the DDG itself.

**__init__**(*def_loc*, *use_loc*, *variable*)

Constructor.

**Parameters**

- **def_loc**
- **use_loc**
- **variable**

**Returns**

class angr.analyses.vsa_ddg.**VSA_DDG**

Bases: *Analysis*

A Data dependency graph based on VSA states. That means we don't (and shouldn't) expect any symbolic expressions.

**__init__**(*vfg=None*, *start_addr=None*, *interfunction_level=0*, *context_sensitivity_level=2*, *keep_data=False*)

Constructor.

**Parameters**

- **vfg** – An already constructed VFG. If not specified, a new VFG will be created with other specified parameters. *vfg* and *start_addr* cannot both be unspecified.
- **start_addr** – The address where to start the analysis (typically, a function's entry point).
- **interfunction_level** – See VFG analysis.
- **context_sensitivity_level** – See VFG analysis.
- **keep_data** – Whether we keep set of addresses as edges in the graph, or just the cardinality of the sets, which can be used as a "weight".

**get_predecessors**(*code_location*)

Returns all predecessors of *code_location*.

**Parameters**
**code_location** – A CodeLocation instance.

**Returns**
A list of all predecessors.

**get_all_nodes**(*simrun_addr*, *stmt_idx*)

Get all DDG nodes matching the given basic block address and statement index.

### 10.3.55 angr.analyses.vtable

class angr.analyses.vtable.**Vtable**

Bases: object

This contains the addr, size and function addresses of a Vtable

**__init__**(*vaddr*, *size*, *func_addrs=None*)

class angr.analyses.vtable.**VtableFinder**

Bases: *Analysis*

This analysis locates Vtables in a binary based on heuristics taken from - "Reconstruction of Class Hierarchies for Decompilation of C++ Programs"

**__init__**()

**is_cross_referenced**(*addr*)

**is_function**(*addr*)

**analyze**()

**create_extract_vtable**(*start_addr*, *sec_size*)

### 10.3.56 angr.analyses.xrefs

**class** angr.analyses.xrefs.**SimEngineXRefsVEX**

Bases: *SimEngineNostmtVEX*[None, None, None]

The VEX engine class for XRefs analysis.

**__init__**(*xref_manager*, *project*, *replacements=None*)

**add_xref**(*xref_type*, *from_loc*, *to_loc*)

**static extract_value_if_concrete**(*expr*)

Extract the concrete value from expr if it is a concrete claripy AST.

**Parameters**
**expr** – A claripy AST.

**Return type**
int | None

**Returns**
A concrete value or None if nothing concrete can be extracted.

**class** angr.analyses.xrefs.**XRefsAnalysis**

Bases: *ForwardAnalysis*, *Analysis*

XRefsAnalysis recovers in-depth x-refs (cross-references) in disassembly code.

Here is an example:

```
.text:
000023C8                LDR     R2, =time_now
000023CA                LDR     R3, [R2]
000023CC                ADDS    R3, #1
000023CE                STR     R3, [R2]
000023D0                BX      LR

.bss:
1FFF36F4 time_now       % 4
```

You will have the following x-refs for time_now:

```
23c8 - offset
23ca - read access
23ce - write access
```

## 10.4 angr.angrdb

**class** angr.angrdb.**AngrDB**

Bases: object

AngrDB provides a storage solution for an angr project, its knowledge bases, and some other types of data. It is designed to use an SQL-based database as the storage backend.

**ALL_TABLES = ['objects']**

**VERSION = 3**

COMPATIBLE_VERSIONS = (1, 2, 3)

__init__(*project=None*, *nullpool=False*)

open_db(*db_str='sqlite:///:memory:'*)

static session_scope(*Session*)

static save_info(*session*, *key*, *value*)

Save an information entry to the database.

**Parameters**

- session
- key
- value

**Returns**

static loaded_type_collection_names()

Primary names of all loaded type collections.

**Return type**
list[str]

static load_type_collections(*names*)

Make sure the type collections *names* are loaded; warn about the ones that cannot be found.

**Return type**
None

**Parameters**
**names** (*list[str]*)

static get_info(*session*, *key*)

Get an information entry from the database.

**Parameters**

- session
- key

**Returns**

update_dbinfo(*session*, *extra_info=None*)

Update the information in database.

**Parameters**

- session
- extra_info (*dict[str, str] | None*)

**Returns**

get_dbinfo(*session*, *extra_info=None*)

Get database information.

**Parameters**

- session
- extra_info (*dict[str, str] | None*)

**Returns**
A dict of information entries.

**db_compatible**(*version*)

Checks if the given database version is compatible with the current AngrDB class.

**Parameters**
**version** (*int*) – The version of the database.

**Returns**
True if compatible, False otherwise.

**Return type**
bool

**invalidate**()

**dump**(*db_path*, *kbs=None*, *extra_info=None*)

**Parameters**

- **kbs** (*list[KnowledgeBase] | None*)
- **extra_info** (*dict[str, Any] | None*)

**load**(*db_path*, *kb_names=None*, *other_kbs=None*, *extra_info=None*)

**Parameters**

- **db_path** (*str*)
- **kb_names** (*list[str] | None*)
- **other_kbs** (*dict[str, KnowledgeBase] | None*)
- **extra_info** (*dict[str, Any] | None*)

## 10.4.1 angr.angrdb.db

**class** angr.angrdb.db.**AngrDB**

Bases: object

AngrDB provides a storage solution for an angr project, its knowledge bases, and some other types of data. It is designed to use an SQL-based database as the storage backend.

**ALL_TABLES = ['objects']**

**VERSION = 3**

**COMPATIBLE_VERSIONS = (1, 2, 3)**

**__init__**(*project=None*, *nullpool=False*)

open_db(*db_str='sqlite:///:memory:'*)

static session_scope(*Session*)

static save_info(*session*, *key*, *value*)

Save an information entry to the database.

**Parameters**

- **session**
- **key**
- **value**

**Returns**

static loaded_type_collection_names()

Primary names of all loaded type collections.

**Return type**
list[str]

static load_type_collections(*names*)

Make sure the type collections *names* are loaded; warn about the ones that cannot be found.

**Return type**
None

**Parameters**
**names** (*list[str]*)

static get_info(*session*, *key*)

Get an information entry from the database.

**Parameters**

- **session**
- **key**

**Returns**

update_dbinfo(*session*, *extra_info=None*)

Update the information in database.

**Parameters**

- **session**
- **extra_info** (*dict[str, str] | None*)

**Returns**

get_dbinfo(*session*, *extra_info=None*)

Get database information.

**Parameters**

- **session**
- **extra_info** (*dict[str, str] | None*)

**Returns**
A dict of information entries.

**db_compatible**(*version*)

Checks if the given database version is compatible with the current AngrDB class.

**Parameters**
**version** (*int*) – The version of the database.

**Returns**
True if compatible, False otherwise.

**Return type**
bool

**invalidate**()

**dump**(*db_path*, *kbs=None*, *extra_info=None*)

**Parameters**

- **kbs** (*list[KnowledgeBase] | None*)
- **extra_info** (*dict[str, Any] | None*)

**load**(*db_path*, *kb_names=None*, *other_kbs=None*, *extra_info=None*)

**Parameters**

- **db_path** (*str*)
- **kb_names** (*list[str] | None*)
- **other_kbs** (*dict[str, KnowledgeBase] | None*)
- **extra_info** (*dict[str, Any] | None*)

### 10.4.2 angr.angrdb.models

**class** angr.angrdb.models.**DbInformation**

Bases: Base

Stores information related to the current database. Basically a key-value store.

**id**

**key**

**value**

**__init__**(***kwargs*)

A simple constructor that allows initialization from kwargs.

Sets attributes on the constructed instance using the names and values in `kwargs`.

Only keys that are present as attributes of the instance's class are allowed. These could be, for example, any mapped columns or relationships.

**class** angr.angrdb.models.**DbObject**

Bases: Base

Models a binary object.

**id**

**main_object**

**path**

**content**

**backend**

**backend_args**

**__init__**(***kwargs*)

A simple constructor that allows initialization from kwargs.

Sets attributes on the constructed instance using the names and values in `kwargs`.

Only keys that are present as attributes of the instance's class are allowed. These could be, for example, any mapped columns or relationships.

**class** angr.angrdb.models.**DbKnowledgeBase**

Bases: `Base`

Models a knowledge base.

**id**

**name**

**cfgs**

**funcs**

**callgraphs**

**xrefs**

**comments**

**bookmarks**

**patterns**

**labels**

**callsite_prototypes**

**var_collections**

**dec_var_collections**

**structured_code**

**decompilation_caches**

**__init__**(***kwargs*)

A simple constructor that allows initialization from kwargs.

Sets attributes on the constructed instance using the names and values in `kwargs`.

Only keys that are present as attributes of the instance's class are allowed. These could be, for example, any mapped columns or relationships.

**class** angr.angrdb.models.**DbCFGModel**

Bases: `Base`

Models a CFGFast instance.

**id**

**kb_id**

**kb**

**ident**

**blob**

**__init__**(***kwargs*)

A simple constructor that allows initialization from kwargs.

Sets attributes on the constructed instance using the names and values in `kwargs`.

Only keys that are present as attributes of the instance's class are allowed. These could be, for example, any mapped columns or relationships.

**class** angr.angrdb.models.**DbFunction**

Bases: `Base`

Models a Function instance.

**id**

**kb_id**

**kb**

**addr**

**blob**

**__init__**(***kwargs*)

A simple constructor that allows initialization from kwargs.

Sets attributes on the constructed instance using the names and values in `kwargs`.

Only keys that are present as attributes of the instance's class are allowed. These could be, for example, any mapped columns or relationships.

**class** angr.angrdb.models.**DbCallGraph**

Bases: `Base`

Models the callgraph of a function manager.

**id**

**kb_id**

**kb**

**blob**

**__init__**(***kwargs*)

A simple constructor that allows initialization from kwargs.

Sets attributes on the constructed instance using the names and values in `kwargs`.

Only keys that are present as attributes of the instance's class are allowed. These could be, for example, any mapped columns or relationships.

class angr.angrdb.models.**DbVariableCollection**

Bases: Base

Models a VariableManagerInternal instance.

**id**

**kb_id**

**kb**

**func_addr**

**ident**

**blob**

**__init__**(***kwargs*)

A simple constructor that allows initialization from kwargs.

Sets attributes on the constructed instance using the names and values in **kwargs**.

Only keys that are present as attributes of the instance's class are allowed. These could be, for example, any mapped columns or relationships.

class angr.angrdb.models.**DbDecVariableCollection**

Bases: Base

Models a VariableManagerInternal instance of the decompilation variable manager (kb.dec_variables). A separate table from variables (the disassembly-level kb.variables) so databases created before it existed remain loadable: create_all adds missing tables.

**id**

**kb_id**

**kb**

**func_addr**

**ident**

**blob**

**__init__**(***kwargs*)

A simple constructor that allows initialization from kwargs.

Sets attributes on the constructed instance using the names and values in **kwargs**.

Only keys that are present as attributes of the instance's class are allowed. These could be, for example, any mapped columns or relationships.

class angr.angrdb.models.**DbStructuredCode**

Bases: Base

Models a StructuredCode instance.

**id**

**kb_id**

**kb**

**func_addr**

**flavor**

**expr_comments**

**stmt_comments**

**configuration**

**const_formats**

**ite_exprs**

**errors**

**__init__**(***kwargs*)

A simple constructor that allows initialization from kwargs.

Sets attributes on the constructed instance using the names and values in `kwargs`.

Only keys that are present as attributes of the instance's class are allowed. These could be, for example, any mapped columns or relationships.

**class** angr.angrdb.models.**DbDecompilationCache**

Bases: `Base`

Models a fully serialized DecompilationCache instance (a protobuf DecompilationCache message). A separate table from `structured_code` (which stores only codegen metadata) so databases created before it existed remain loadable: `create_all` adds missing tables.

**id**

**kb_id**

**kb**

**func_addr**

**flavor**

**blob**

**__init__**(***kwargs*)

A simple constructor that allows initialization from kwargs.

Sets attributes on the constructed instance using the names and values in `kwargs`.

Only keys that are present as attributes of the instance's class are allowed. These could be, for example, any mapped columns or relationships.

**class** angr.angrdb.models.**DbXRefs**

Bases: `Base`

Models an XRefManager instance.

**id**

**kb_id**

**kb**

**blob**

**__init__**(***kwargs*)

A simple constructor that allows initialization from kwargs.

Sets attributes on the constructed instance using the names and values in `kwargs`.

Only keys that are present as attributes of the instance's class are allowed. These could be, for example, any mapped columns or relationships.

class angr.angrdb.models.**DbComment**

Bases: `Base`

Models a comment.

**id**

**kb_id**

**kb**

**addr**

**comment**

**type**

**__init__**(***kwargs*)

A simple constructor that allows initialization from kwargs.

Sets attributes on the constructed instance using the names and values in `kwargs`.

Only keys that are present as attributes of the instance's class are allowed. These could be, for example, any mapped columns or relationships.

class angr.angrdb.models.**DbBookmark**

Bases: `Base`

Models a bookmark.

**id**

**kb_id**

**kb**

**addr**

**label**

**created_at**

**__init__**(***kwargs*)

A simple constructor that allows initialization from kwargs.

Sets attributes on the constructed instance using the names and values in `kwargs`.

Only keys that are present as attributes of the instance's class are allowed. These could be, for example, any mapped columns or relationships.

class angr.angrdb.models.**DbPattern**

Bases: Base

Models a user-authored fuzzy pattern; the pattern itself is stored as JSON.

**id**

**kb_id**

**kb**

**name**

**enabled**

**min_similarity**

**origin_func**

**require_verified**

**created_at**

**pattern**

**__init__**(***kwargs*)

A simple constructor that allows initialization from kwargs.

Sets attributes on the constructed instance using the names and values in `kwargs`.

Only keys that are present as attributes of the instance's class are allowed. These could be, for example, any mapped columns or relationships.

class angr.angrdb.models.**DbLabel**

Bases: Base

Models a label.

**id**

**kb_id**

**kb**

**addr**

**name**

**__init__**(***kwargs*)

A simple constructor that allows initialization from kwargs.

Sets attributes on the constructed instance using the names and values in `kwargs`.

Only keys that are present as attributes of the instance's class are allowed. These could be, for example, any mapped columns or relationships.

class angr.angrdb.models.**DbCallsitePrototype**

Bases: Base

Models one call-site prototype: the calling convention and prototype of a callee at a call site, per flavor and kind.

**id**

**kb_id**

**kb**

**flavor**

**addr**

**kind**

**cc**

**prototype**

**__init__**(***kwargs*)

A simple constructor that allows initialization from kwargs.

Sets attributes on the constructed instance using the names and values in `kwargs`.

Only keys that are present as attributes of the instance's class are allowed. These could be, for example, any mapped columns or relationships.

### 10.4.3 angr.angrdb.serializers

**class** angr.angrdb.serializers.**KnowledgeBaseSerializer**

Bases: `object`

Serialize/unserialize a KnowledgeBase object.

**static dump**(*session*, *kb*)

**Parameters**

- **session** – The database session object.
- **kb** (*KnowledgeBase*) – The KnowledgeBase instance to serialize.

**Returns**
None

**static load**(*session*, *project*, *name*)

**Parameters**
**session**

**Returns**

**class** angr.angrdb.serializers.**LoaderSerializer**

Bases: `object`

Serialize/unserialize a CLE Loader object into/from an angr DB.

Corner cases:

- For certain backends (e.g., CART), we do not store the data of the main object. angr will unpack the CART file again after loading the database.

**NO_MAINBIN_BACKENDS = [<class 'cle.backends.cartfile.CARTFile'>]**

**LOAD_ARG_BLACKLIST = {'is_main_bin', 'loader'}**

backend2name = {<class 'cle.backends.blob.Blob'>: 'blob', <class 'cle.backends.cartfile.CARTFile'>: 'cart', <class 'cle.backends.cgc.backedcgc.BackedCGC'>: 'backedcgc', <class 'cle.backends.cgc.cgc.CGC'>: 'cgc', <class 'cle.backends.coff.Coff'>: 'COFF', <class 'cle.backends.elf.elf.ELF'>: 'elf', <class 'cle.backends.elf.elfcore.ELFCore'>: 'elfcore', <class 'cle.backends.ihex.Hex'>: 'hex', <class 'cle.backends.java.apk.Apk'>: 'apk', <class 'cle.backends.java.dex.Dex'>: 'dex', <class 'cle.backends.java.jar.Jar'>: 'jar', <class 'cle.backends.macho.macho.MachO'>: 'mach-o', <class 'cle.backends.minidump.Minidump'>: 'minidump', <class 'cle.backends.mz.MZ'>: 'mz', <class 'cle.backends.named_region.NamedRegion'>: 'named_region', <class 'cle.backends.pe.pe.PE'>: 'pe', <class 'cle.backends.srec.SRec'>: 'srec', <class 'cle.backends.static_archive.StaticArchive'>: 'AR', <class 'cle.backends.stm32.STM32Backend'>: 'stm32', <class 'cle.backends.te.TE'>: 'te', <class 'cle.backends.uefi_firmware.UefiFirmware'>: 'uefi', <class 'cle.backends.universal2.Universal2'>: 'Universal2', <class 'cle.backends.xbe.XBE'>: 'xbe'}

static json_serialize_load_args(*load_args*)

**Return type**
str

**Parameters**
**load_args** (*dict[str, Any]*)

static should_skip_main_binary(*loader*)

**Return type**
tuple[bool, Backend | None]

static dump(*session*, *loader*)

static load(*session*)

### Submodules

### angr.angrdb.serializers.bookmarks

class angr.angrdb.serializers.bookmarks.**BookmarksSerializer**

Bases: object

Serialize/unserialize bookmarks to/from a database session.

static **dump**(*session*, *db_kb*, *bookmarks*)

**Parameters**

- **session**
- **db_kb** (DbKnowledgeBase)
- **bookmarks** (Bookmarks)

**Returns**
None

static **load**(*session*, *db_kb*, *kb*)

**Parameters**

- **session**
- **db_kb** (DbKnowledgeBase)
- **kb** (KnowledgeBase)

**Returns**

### angr.angrdb.serializers.callgraph

class angr.angrdb.serializers.callgraph.**CallGraphSerializer**

Bases: object

Serialize/unserialize the callgraph of a function manager (a networkx.MultiDiGraph whose nodes are function addresses).

The graph is stored as a JSON document with the exact node set as well as all edges, including their keys and data dicts, so that edge multiplicity and edge data round-trip exactly.

static **dump**(*session*, *db_kb*, *callgraph*)

**Parameters**

- **session**
- **db_kb** (*DbKnowledgeBase*) – The database object for KnowledgeBase.
- **callgraph** (MultiDiGraph) – The callgraph to dump.

**Return type**
None

static **load**(*session*, *db_kb*)

**Parameters**

- **session**
- **db_kb** (*DbKnowledgeBase*) – The database object for KnowledgeBase.

**Return type**
MultiDiGraph | None

**Returns**
The loaded callgraph, or None if no callgraph is stored in the database (e.g., for databases created before callgraph serialization was introduced).

### angr.angrdb.serializers.callsite_prototypes

**class** angr.angrdb.serializers.callsite_prototypes.**CallsitePrototypesSerializer**

Bases: object

Serialize/unserialize call-site prototypes of every flavor to/from a database session.

**static dump**(*session*, *db_kb*, *callsite_prototypes*)

**Parameters**
**callsite_prototypes** (CallsitePrototypes)

**static load**(*session*, *db_kb*, *kb*)

**Return type**
*CallsitePrototypes*

### angr.angrdb.serializers.cfg_model

**class** angr.angrdb.serializers.cfg_model.**CFGModelSerializer**

Bases: object

Serialize/unserialize a CFGModel.

**static dump**(*session*, *db_kb*, *ident*, *cfg_model*)

**Parameters**

- **session**
- **db_kb** (DbKnowledgeBase) – The database object for KnowledgeBase.
- **ident** (*str*) – Identifier of the CFG model.
- **cfg_model** (CFGModel) – The CFG model to dump.

**Returns**
None

**static load**(*session*, *db_kb*, *ident*, *cfg_manager*, *loader=None*)

### angr.angrdb.serializers.comments

**class** angr.angrdb.serializers.comments.**CommentsSerializer**

Bases: object

Serialize/unserialize comments to/from a database session.

**static dump**(*session*, *db_kb*, *comments*)

**Parameters**

- **session**
- **db_kb** (DbKnowledgeBase)
- **comments** (Comments)

**Returns**
None

static load(*session*, *db_kb*, *kb*)

**Parameters**

- **session**
- **db_kb** (DbKnowledgeBase)
- **kb** (KnowledgeBase)

**Returns**

### angr.angrdb.serializers.funcs

class angr.angrdb.serializers.funcs.**FunctionManagerSerializer**

Bases: object

Serialize/unserialize a function manager and its functions.

static dump(*session*, *db_kb*, *func_manager*)

**Parameters**

- **session**
- **db_kb** (*DbKnowledgeBase*)
- **func_manager** (*FunctionManager*)

**Returns**

static load(*session*, *db_kb*, *kb*, *callgraph=None*, *cfg_model=None*)

**Parameters**

- **session**
- **db_kb** (*DbKnowledgeBase*)
- **kb** (*KnowledgeBase*)
- **callgraph** (MultiDiGraph | None) – A deserialized callgraph (if the database stores one). When provided, it is used directly and the (much slower) callgraph rebuilding logic is skipped.
- **cfg_model** (*CFGModel* | None) – An optional CFG model. When provided, the function_address member of all CFG nodes that belong to a function will be set accordingly.

**Returns**

A loaded function manager.

### angr.angrdb.serializers.kb

class angr.angrdb.serializers.kb.**KnowledgeBaseSerializer**

Bases: object

Serialize/unserialize a KnowledgeBase object.

static dump(*session*, *kb*)

**Parameters**

- **session** – The database session object.
- **kb** (*KnowledgeBase*) – The KnowledgeBase instance to serialize.

**Returns**
None

`static load`(*session*, *project*, *name*)

**Parameters**
**session**

**Returns**

### angr.angrdb.serializers.labels

`class angr.angrdb.serializers.labels.LabelsSerializer`

Bases: `object`

Serialize/unserialize labels to/from a database session.

`static dump`(*session*, *db_kb*, *labels*)

**Parameters**

- **session**
- **db_kb** (`DbKnowledgeBase`)
- **labels** (`Labels`)

**Returns**
None

`static load`(*session*, *db_kb*, *kb*)

**Parameters**

- **session**
- **db_kb** (`DbKnowledgeBase`)
- **kb** (`KnowledgeBase`)

**Returns**

### angr.angrdb.serializers.loader

`class angr.angrdb.serializers.loader.LoadArgsJSONEncoder`

Bases: `JSONEncoder`

A JSON encoder that supports serializing bytes.

`class angr.angrdb.serializers.loader.LoadArgsJSONDecoder`

Bases: `JSONDecoder`

A JSON decoder that supports unserializing into bytes.

`class angr.angrdb.serializers.loader.LoaderSerializer`

Bases: `object`

Serialize/unserialize a CLE Loader object into/from an angr DB.

Corner cases:

- For certain backends (e.g., CART), we do not store the data of the main object. angr will unpack the CART file again after loading the database.

NO_MAINBIN_BACKENDS = [<class 'cle.backends.cartfile.CARTFile'>]

LOAD_ARG_BLACKLIST = {'is_main_bin', 'loader'}

backend2name = {<class 'cle.backends.blob.Blob'>: 'blob', <class 'cle.backends.cartfile.CARTFile'>: 'cart', <class 'cle.backends.cgc.backedcgc.BackedCGC'>: 'backedcgc', <class 'cle.backends.cgc.cgc.CGC'>: 'cgc', <class 'cle.backends.coff.Coff'>: 'COFF', <class 'cle.backends.elf.elf.ELF'>: 'elf', <class 'cle.backends.elf.elfcore.ELFCore'>: 'elfcore', <class 'cle.backends.ihex.Hex'>: 'hex', <class 'cle.backends.java.apk.Apk'>: 'apk', <class 'cle.backends.java.dex.Dex'>: 'dex', <class 'cle.backends.java.jar.Jar'>: 'jar', <class 'cle.backends.macho.macho.MachO'>: 'mach-o', <class 'cle.backends.minidump.Minidump'>: 'minidump', <class 'cle.backends.mz.MZ'>: 'mz', <class 'cle.backends.named_region.NamedRegion'>: 'named_region', <class 'cle.backends.pe.pe.PE'>: 'pe', <class 'cle.backends.srec.SRec'>: 'srec', <class 'cle.backends.static_archive.StaticArchive'>: 'AR', <class 'cle.backends.stm32.STM32Backend'>: 'stm32', <class 'cle.backends.te.TE'>: 'te', <class 'cle.backends.uefi_firmware.UefiFirmware'>: 'uefi', <class 'cle.backends.universal2.Universal2'>: 'Universal2', <class 'cle.backends.xbe.XBE'>: 'xbe'}

static json_serialize_load_args(*load_args*)

**Return type**
str

**Parameters**
**load_args** (*dict[str, Any]*)

static should_skip_main_binary(*loader*)

**Return type**
tuple[bool, Backend | None]

static dump(*session*, *loader*)

static load(*session*)

### angr.angrdb.serializers.patterns

class angr.angrdb.serializers.patterns.**PatternsSerializer**

Bases: object

Serialize/unserialize user-authored fuzzy patterns to/from a database session.

static dump(*session*, *db_kb*, *patterns*)

**Parameters**
**patterns** (Patterns)

static load(*session*, *db_kb*, *kb*)

**Return type**
*Patterns*

### angr.angrdb.serializers.structured_code

**class** angr.angrdb.serializers.structured_code.**ConstFormatsSerializer**

Bases: object

Serialize/deserialize the constant formats dictionary.

**static to_json**(*const_formats*)

**Return type**
dict[int, dict[str, dict[str, bool]]]

**Parameters**
**const_formats** (*dict[IdentType, dict[str, bool]]*)

**static from_json**(*data*)

**Return type**
dict[tuple[int, int, str], dict[str, bool]]

**Parameters**
**data** (*dict[int, dict[str, dict[str, str | bool]]]*)

**class** angr.angrdb.serializers.structured_code.**StructuredCodeManagerSerializer**

Bases: object

Serialize/deserialize a structured code manager.

**static dump**(*session*, *db_kb*, *code_manager*)

Store every decompilation cache as its fully serialized protobuf bytes (the `decompilation_caches` table). Caches that cannot be serialized (e.g. dummy or rust-flavor codegens) fall back to the legacy `structured_code` rows storing codegen metadata only.

**Parameters**

- **session**
- **db_kb** (*DbKnowledgeBase*)
- **code_manager** (*StructuredCodeManager*)

**Returns**

**static dict_strkey_to_intkey**(*d*)

**Return type**
dict[int, Any]

**Parameters**
**d** (*dict[str, Any]*)

**static load**(*session*, *db_kb*, *kb*)

Load decompilation caches: fully serialized caches from the `decompilation_caches` table first, then legacy `structured_code` rows (from this database or from old databases) for any key not already loaded.

**Parameters**

- **session**
- **db_kb** (*DbKnowledgeBase*)
- **kb** (*KnowledgeBase*)

**Return type**
*StructuredCodeManager*

**Returns**
A loaded structured code manager

### angr.angrdb.serializers.variables

**class** angr.angrdb.serializers.variables.**VariableManagerSerializer**

Bases: object

Serialize/unserialize a variable manager and its variables.

The same machinery serializes the disassembly-level manager (`kb.variables` into the `variables` table) and the decompilation manager (`kb.dec_variables` into the `dec_variables` table); the target table and manager class are parameterized.

**static dump**(*session*, *db_kb*, *var_manager*, *table=<class 'angr.angrdb.models.DbVariableCollection'>*)

**Parameters**

- **db_kb** (DbKnowledgeBase)
- **var_manager** (VariableManager)

**static dump_dvars**(*session*, *db_kb*, *var_manager*)

**Parameters**

- **db_kb** (DbKnowledgeBase)
- **var_manager** (VariableManager)

**static load**(*session*, *db_kb*, *kb*, *ident=None*, *table=<class 'angr.angrdb.models.DbVariableCollection'>*)

**Parameters**

- **db_kb** (DbKnowledgeBase)
- **kb** (KnowledgeBase)

**static load_dvars**(*session*, *db_kb*, *kb*, *ident=None*)

**Parameters**

- **db_kb** (DbKnowledgeBase)
- **kb** (KnowledgeBase)

**static load_internal**(*db_varcoll*, *variable_manager*)

**Return type**
*VariableManagerInternal*

**Parameters**
**variable_manager** (VariableManager)

### angr.angrdb.serializers.xrefs

**class** angr.angrdb.serializers.xrefs.**XRefsSerializer**

Bases: object

Serialize/unserialize an XRefs object to/from a database session.

**static dump**(*session*, *db_kb*, *xrefs*)

**Parameters**

- **session**
- **db_kb** (DbKnowledgeBase)
- **xrefs** (XRefManager)

**Returns**

**static load**(*session*, *db_kb*, *kb*, *cfg_model=None*)

**Parameters**

- **session**
- **db_kb** (DbKnowledgeBase)
- **kb** (KnowledgeBase)
- **cfg_model** (CFGModel)

**Returns**

### 10.4.4 angr.angrdb.v1

angrDb Version 1 compatibility logic.

angrDb v1 stores function graphs as per-block and per-edge protobuf messages. We will deprecate the v1 compatibility logic in about a year's time.

**class** angr.angrdb.v1.**AngrDbV1**

Bases: object

Reader and writer of the angrDb v1-specific data types. Static methods only.

**static serialize_function**(*function*)

Serialize a Function with its metadata as FunctionParser.serialize() writes it and its graph in the angrDb v1 per-block / per-edge layout.

**Return type**
Function

**static local_block_addrs**(*cmsg*)

The addresses of the local blocks of an angrDb v1 function record, without building the Function.

**Return type**
set[int]

**static write_graph**(*function*, *obj*)

**Return type**
None

**Parameters**
**function** (Function)

**static node_to_block_cmsg**(*node*)

**Return type**
Block

**static node_from_block_cmsg**(*block*, *project*)

**static parse_function**(*cmsg*, *obj*, *project*, *meta_only*)

Rebuild the graph of *obj* from the per-block / per-edge layout of *cmsg*.

**Parameters**
**meta_only** (*bool*)

**static add_endpoint**(*func*, *block*, *endpoint_type*)

**Return type**
None

**Parameters**
**block** (CodeNode)

**static get_external_node**(*addr*, *external_nodes*, *external_func_addrs*, *project*)

**Return type**
*CodeNode*

**Parameters**

- **external_nodes** (*dict[int, list[CodeNode]]*)
- **external_func_addrs** (*set[int]*)

### 10.4.5 angr.angrdb.v2

**class** angr.angrdb.v2.**AngrDbV2**

Bases: object

Reader and writer of the angrDb v2-specific CFG layout: one Edge message per CFG edge, addressed by node address (v3 stores the graph as segment blobs instead). Static methods only.

**static edge_data**(*edge_pb2*)

**Return type**
dict

**static parse_cfg_edges**(*cmsg*, *model*)

Add the per-edge messages of a v2 CFG record to a model whose nodes are already in place.

**Return type**
None

**Parameters**
**model** (CFGModel)

**static parse_cfg_edges_spilled**(*cmsg*, *graph*)

Like parse_cfg_edges, for a graph whose nodes were bulk-imported without CFGNode objects.

**Return type**
None

**Parameters**
**graph** (SpillingCFG)

**static serialize_cfg**(*model*)

Serialize a CFG model in the v2 layout: nodes plus per-edge messages, no graph segments.

**Parameters**
**model** (CFGModel)

## 10.5 angr.annocfg

**class** angr.annocfg.**AnnotatedCFG**

Bases: object

AnnotatedCFG is a control flow graph with statement whitelists and exit whitelists to describe a slice of the program.

**__init__**(*project*, *cfg=None*, *detect_loops=False*)

Constructor.

**Parameters**

- **project** – The angr Project instance
- **cfg** – Control flow graph.
- **detect_loops**

**from_digraph**(*digraph*)

Initialize this AnnotatedCFG object with a networkx.DiGraph consisting of the following form of nodes:

Tuples like (block address, statement ID)

Those nodes are connected by edges indicating the execution flow.

**Parameters**
**digraph** (*networkx.DiGraph*) – A networkx.DiGraph object

**get_addr**(*run*)

**add_block_to_whitelist**(*block*)

**add_statements_to_whitelist**(*block*, *stmt_ids*)

**add_exit_to_whitelist**(*run_from*, *run_to*)

**set_last_statement**(*block_addr*, *stmt_id*)

**add_loop**(*loop_tuple*)

A loop tuple contains a series of IRSB addresses that form a loop. Ideally it always starts with the first IRSB that we meet during the execution.

**should_take_exit**(*addr_from*, *addr_to*)

**should_execute_statement**(*addr*, *stmt_id*)

**get_run**(*addr*)

**get_whitelisted_statements**(*addr*)

**Return type**
list[int] | None

**Returns**
True if all statements are whitelisted

**get_last_statement_index**(*addr*)

Get the statement index of the last statement to execute in the basic block specified by *addr*.

**Parameters**
**addr** (*int*) – Address of the basic block.

**Returns**
The statement index of the last statement to be executed in the block. Usually if the default exit is taken, it will be the last statement to execute. If the block is not in the slice or we should never take any exit going to this block, None is returned.

**Return type**
int or None

**get_loops**()

**get_targets**(*source_addr*)

**dbg_repr**()

**dbg_print_irsb**(*irsb_addr*, *project=None*)
Pretty-print an IRSB with whitelist information

**keep_path**(*path*)
Given a path, returns True if the path should be kept, False if it should be cut.

**merge_points**(*path*)

**successor_func**(*path*)
Callback routine that takes in a path, and returns all feasible successors to path group. This callback routine should be passed to the keyword argument "successor_func" of PathGroup.step().

**Parameters**
**path** – A Path instance.

**Returns**
A list of all feasible Path successors.

## 10.6 angr.blade

**exception** angr.blade.**BadJumpkindNotification**
Bases: Exception

Notifies the caller that the jumpkind is bad (e.g., Ijk_NoDecode)

**class** angr.blade.**Blade**
Bases: object

Blade is a light-weight program slicer that works with networkx DiGraph containing CFGNodes. It is meant to be used in angr for small or on-the-fly analyses.

**__init__**(*graph*, *dst_run*, *dst_stmt_idx*, *direction='backward'*, *project=None*, *cfg=None*, *ignore_sp=False*, *ignore_bp=False*, *ignored_regs=None*, *max_level=3*, *base_state=None*, *stop_at_calls=False*, *cross_insn_opt=False*, *max_predecessors=10*, *include_imarks=True*, *control_dependence=True*, *block_cache=None*)

**Parameters**

- **graph** (DiGraph) – A graph representing the control flow graph. Note that it does not take angr.analyses.CFGEmulated or angr.analyses.CFGFast.
- **dst_run** (int) – An address specifying the target SimRun.
- **dst_stmt_idx** (int) – The target statement index. -1 means executing until the last statement.

- **direction** (str) – 'backward' or 'forward' slicing. Forward slicing is not yet supported.
- **project** (*angr.Project*) – The project instance.
- **cfg** (*angr.analyses.CFGBase*) – the CFG instance. It will be made mandatory later.
- **ignore_sp** (bool) – Whether the stack pointer should be ignored in dependency tracking. Any dependency from/to stack pointers will be ignored if this options is True.
- **ignore_bp** (bool) – Whether the base pointer should be ignored or not.
- **max_level** (int) – The maximum number of blocks that we trace back for.
- **stop_at_calls** (bool) – Limit slicing within a single function. Do not proceed when encounters a call edge.
- **include_imarks** (bool) – Should IMarks (instruction boundaries) be included in the slice.
- **control_dependence** (bool) – Whether to consider control dependencies. If True, the temps controlling conditional exits will be added to the tainting set.
- **block_cache** (dict[int, *Block*] | None) – Lifted blocks keyed by address, shared with the caller so that slices of the same region (e.g., at growing depths) lift each block once. The caller must only share it between slices lifted with the same parameters.
- **max_predecessors** (*int*)

**Returns**
None

**property slice**

**get_block**(*addr*)

The block at addr, lifted with this slice's parameters (cached).

**Return type**
*Block*

**Parameters**
**addr** (*int*)

**dbg_repr**(*arch=None*)

## 10.7 angr.block

**class** angr.block.**DisassemblerBlock**

Bases: object

Helper class to represent a block of disassembled target architecture instructions

**__init__**(*addr*, *insns*, *thumb*, *arch*)

**addr**

**insns**

**thumb**

**arch**

**pp**()

class angr.block.**DisassemblerInsn**

Bases: object

Helper class to represent a disassembled target architecture instruction

**property size:** int

**property address:** int

**property mnemonic:** str

**property op_str:** str

class angr.block.**CapstoneBlock**

Bases: *DisassemblerBlock*

Deep copy of the capstone blocks, which have serious issues with having extended lifespans outside of capstone itself

class angr.block.**CapstoneInsn**

Bases: *DisassemblerInsn*

Represents a capstone instruction.

**__init__**(*capstone_insn*)

**insn**

**property size:** int

**property address:** int

**property mnemonic:** str

**property op_str:** str

class angr.block.**PCodeBlock**

Bases: *DisassemblerBlock*

Deep copy of the pcode blocks

class angr.block.**PCodeInsn**

Bases: *DisassemblerInsn*

Represents a capstone instruction.

**__init__**(*pcode_insn*)

**insn**

**property size:** int

**property address:** int

**property mnemonic:** str

**property op_str:** str

class angr.block.**Block**

Bases: *Serializable*

Represents a basic block in a binary or a program.

BLOCK_MAX_SIZE = 4096

__init__(*addr*, *project=None*, *arch=None*, *size=None*, *max_size=None*, *byte_string=None*, *thumb=False*, *backup_state=None*, *extra_stop_points=None*, *opt_level=None*, *num_inst=None*, *traceflags=0*, *strict_block_end=None*, *collect_data_refs=False*, *cross_insn_opt=True*, *load_from_ro_regions=False*, *const_prop=False*, *initial_regs=None*, *skip_stmts=False*)

**Parameters**
**arch** (*Arch | None*)

arch

addr

thumb

size

pp(***kwargs*)

set_initial_regs()

static reset_initial_regs()

property vex: IRSB | *IRSB*

property vex_nostmt

property disassembly: *DisassemblerBlock*

Provide a disassembly object using whatever disassembler is available

property capstone: *CapstoneBlock*

property pcode: *PCodeBlock*

property codenode

property bytes: *bytes* | None

property instructions: int

property instruction_addrs

class angr.block.SootBlock

Bases: object

Represents a Soot IR basic block.

__init__(*addr*, ***, *project*, *arch*)

**Parameters**

- **project** (Project)
- **arch** (*Arch*)

property soot

property size

property codenode

## 10.8 angr.callable

**class** angr.callable.**Callable**

Bases: object

Callable is a representation of a function in the binary that can be interacted with like a native python function.

If you set perform_merge=True (the default), the result will be returned to you, and you can get the result state with callable.result_state.

Otherwise, you can get the resulting simulation manager at callable.result_path_group.

**__init__**(*project*, *addr*, *prototype=None*, *concrete_only=False*, *perform_merge=True*, *base_state=None*, *toc=None*, *cc=None*, *add_options=None*, *remove_options=None*, *step_limit=None*, *techniques=None*)

**Parameters**

- **project** (*Project*) – The project to operate on
- **addr** (int) – The address of the function to use
- **prototype** (*SimTypeFunction* | None) – The signature of the calls you would like to make. This really shouldn't be optional.
- **concrete_only** – Throw an exception if the execution splits into multiple paths
- **perform_merge** – Merge all result states into one at the end (only relevant if concrete_only=False)
- **base_state** (*SimState* | None) – The state from which to do these runs
- **toc** – The address of the table of contents for ppc64
- **cc** (*SimCC* | None) – The SimCC to use for a calling convention
- **add_options** (*set[str] | None*)
- **remove_options** (*set[str] | None*)
- **step_limit** (*int | None*)
- **techniques** (*list[ExplorationTechnique] | None*)

**set_base_state**(*state*)

Swap out the state you'd like to use to perform the call.

**Parameters**
**state** – The state to use to perform the call

**perform_call**(**args*, *prototype=None*)

**call_c**(*c_args*)

Call this Callable with a string of C-style arguments.

**Parameters**
**c_args** (*str*) – C-style arguments.

**Returns**
The return value from the call.

**Return type**
claripy.Ast

## 10.9 angr.calling_conventions

**class** angr.calling_conventions.**PointerWrapper**

Bases: object

**__init__**(*value*, *buffer=False*)

**class** angr.calling_conventions.**AllocHelper**

Bases: object

**__init__**(*ptrsize*)

**alloc**(*size*)

**dump**(*val*, *state*, *loc=None*)

**translate**(*val*, *base*)

**apply**(*state*, *base*)

**size**()

**classmethod calc_size**(*val*, *arch*)

**classmethod stack_loc**(*val*, *arch*, *offset=0*)

angr.calling_conventions.**opaque_cpp_class**(*ty*)

Whether `ty` is a C++ class whose definition angr never saw.

`sim_type` builds one of these from a demangled name it cannot resolve: no members, and a size forced to one word. There is no layout to lay out.

**Return type**
bool

**Parameters**
**ty** (SimType)

angr.calling_conventions.**refine_locs_with_struct_type**(*arch*, *locs*, *arg_type*, *offset=0*, *treat_bot_as_int=True*, *treat_unsupported_as_int=True*)

**Parameters**

- **arch** (*Arch*)
- **locs** (*list*)
- **arg_type** (SimType)
- **offset** (*int*)

**class** angr.calling_conventions.**SerializableIterator**

Bases: object

**getstate**()

**setstate**(*state*)

**class** angr.calling_conventions.**SerializableListIterator**

Bases: *SerializableIterator*

__init__(*lst*)

getstate()

setstate(*state*)

class angr.calling_conventions.**SerializableCounter**

Bases: *SerializableIterator*

__init__(*start*, *stride*, *mapping=<function SerializableCounter.<lambda>>*)

getstate()

setstate(*state*)

class angr.calling_conventions.**SimFunctionArgument**

Bases: object

Represent a generic function argument.

**Variables**

- **size** (*int*) – The size of the argument, in number of bytes.
- **is_fp** (*bool*) – Whether loads from this location should return a floating point bitvector

__init__(*size*, *is_fp=False*)

**Parameters**

- **size** (*int*)
- **is_fp** (*bool*)

check_value_set(*value*, *arch*)

check_value_get(*value*)

set_value(*state*, *value*, ***kwargs*)

get_value(*state*, ***kwargs*)

refine(*size*, *arch=None*, *offset=None*, *is_fp=None*)

get_footprint()

Return a list of SimRegArg and SimStackArgs that are the base components used for this location

**Return type**

Iterable[*SimRegArg* | *SimStackArg*]

class angr.calling_conventions.**SimRegArg**

Bases: *SimFunctionArgument*

Represents a function argument that has been passed in a register.

**Variables**

- **reg_name** (string) – The name of the represented register.
- **size** (*int*) – The size of the data to store, in number of bytes.
- **reg_offset** – The offset into the register to start storing data.
- **clear_entire_reg** – Whether a store to this register should zero the unused parts of the register.

- **is_fp** (*bool*) – Whether loads from this location should return a floating point bitvector

**__init__**(*reg_name*, *size*, *reg_offset=0*, *is_fp=False*, *clear_entire_reg=False*)

**Parameters**

- **reg_name** (*str*)
- **size** (*int*)

**check_offset**(*arch*)

**Return type**
int

**set_value**(*state*, *value*, ***kwargs*)

**get_value**(*state*, ***kwargs*)

**refine**(*size*, *arch=None*, *offset=None*, *is_fp=None*)

**sse_extend**()

**class** angr.calling_conventions.**SimStackArg**

Bases: *SimFunctionArgument*

Represents a function argument that has been passed on the stack.

**Variables**

- **stack_offset** (*int*) – The position of the argument relative to the stack pointer after the function prelude.
- **size** (*int*) – The size of the argument, in number of bytes.
- **is_fp** (*bool*) – Whether loads from this location should return a floating point bitvector

**__init__**(*stack_offset*, *size*, *is_fp=False*)

**Parameters**

- **stack_offset** (*int*)
- **size** (*int*)
- **is_fp** (*bool*)

**stack_offset:** **int**

**set_value**(*state*, *value*, *stack_base=None*, ***kwargs*)

**get_value**(*state*, *stack_base=None*, ***kwargs*)

**refine**(*size*, *arch=None*, *offset=None*, *is_fp=None*)

**class** angr.calling_conventions.**SimComboArg**

Bases: *SimFunctionArgument*, Generic[T]

An argument which spans multiple storage locations. Locations should be given least-significant first.

**__init__**(*locations*, *is_fp=False*)

**Parameters**
**locations** (*list[T]*)

**set_value**(*state*, *value*, ***kwargs*)

**get_value**(*state*, ***kwargs*)

**class** angr.calling_conventions.**SimStructArg**

Bases: *SimFunctionArgument*

An argument which de/serializes a struct from a list of storage locations

**Variables**

- **struct** – The simtype describing the structure
- **locs** – The storage locations to use

**__init__**(*struct*, *locs*)

**Parameters**

- **struct** (SimStruct)
- **locs** (*dict[str, SimFunctionArgument]*)

**get_single_footprint**()

**Return type**
*SimStackArg* | *SimRegArg* | *SimComboArg*

**get_value**(*state*, ***kwargs*)

**set_value**(*state*, *value*, ***kwargs*)

**class** angr.calling_conventions.**SimArrayArg**

Bases: *SimFunctionArgument*

**__init__**(*locs*)

**get_value**(*state*, ***kwargs*)

**set_value**(*state*, *value*, ***kwargs*)

**class** angr.calling_conventions.**SimReferenceArgument**

Bases: *SimFunctionArgument*

A function argument which is passed by reference.

**Variables**

- **ptr_loc** – The location the reference's pointer is stored
- **main_loc** – A SimStackArgument describing how to load the argument's value as if it were stored at offset zero on the stack. It will be passed `stack_base=ptr_loc.get_value(state)`

**__init__**(*ptr_loc*, *main_loc*)

**Parameters**

- **ptr_loc** (SimFunctionArgument)
- **main_loc** (SimFunctionArgument)

**get_value**(*state*, ***kwargs*)

**set_value**(*state*, *value*, ***kwargs*)

**class** angr.calling_conventions.**ArgSession**

Bases: object

A class to keep track of the state accumulated in laying parameters out into memory

**__init__**(*cc*)

**cc**

**fp_iter**

**int_iter**

**both_iter**

**getstate**()

**setstate**(*state*)

**class** angr.calling_conventions.**UsercallArgSession**

Bases: object

An argsession for use with SimCCUsercall

**__init__**(*cc*)

**cc**

**real_args**

**getstate**()

**setstate**(*state*)

**class** angr.calling_conventions.**SimCC**

Bases: object

A calling convention allows you to extract from a state the data passed from function to function by calls and returns. Most of the methods provided by SimCC that operate on a state assume that the program is just after a call but just before stack frame allocation, though this may be overridden with the *stack_base* parameter to each individual method.

This is the base class for all calling conventions.

**__init__**(*arch*, *x87_args=0*)

**Parameters**

- **arch** (Arch) – The Archinfo arch for this CC
- **x87_args** (int) – How many leading arguments are passed on the x87 stack (st(0), st(1), ...) and popped by the callee, as by MSVC's _CI* and _ftol helpers.

**ARG_REGS: list[str] = []**

**FP_ARG_REGS: list[str] = []**

**x87_args: int = 0**

**FP_RET_WHOLE_FUNCTION_SCAN: bool = False**

STACKARG_SP_BUFF = 0

STACKARG_SP_DIFF = 0

CALLER_SAVED_REGS: list[str] = []

RETURN_ADDR: *SimFunctionArgument* | None = None

RETURN_VAL: *SimFunctionArgument* | None = None

OVERFLOW_RETURN_VAL: *SimFunctionArgument* | None = None

FP_RETURN_VAL: *SimFunctionArgument* | None = None

ARCH: type[Arch] | None = None

EXTRA_ARCHES: tuple[type[Arch], ...] = ()

CALLEE_CLEANUP = False

STACK_ALIGNMENT = 1

ARG_SLOT_SIZE: int | None = None

ARG_REG_SANITY_FILTER = False

STRICT_CALLER_SAVED_MATCH = True

SHARED_ARG_SLOTS = False

classmethod arg_reg_offsets(*arch*)

Every register file offset covered by this convention's argument registers.

**Return type**
frozenset[int]

**Parameters**
**arch** (*Arch*)

property arg_slot_size: int

The width in bytes of one argument slot. See ARG_SLOT_SIZE.

property int_args

Iterate through all the possible arg positions that can only be used to store integer or pointer values.

Returns an iterator of SimFunctionArguments

property memory_args

Iterate through all the possible arg positions that can be used to store any kind of argument.

Returns an iterator of SimFunctionArguments

property fp_args

Iterate through all the possible arg positions that can only be used to store floating point values.

Returns an iterator of SimFunctionArguments

is_fp_arg(*arg*)

This should take a SimFunctionArgument instance and return whether or not that argument is a floating-point argument.

**Returns True for MUST be a floating point arg,**
False for MUST NOT be a floating point arg, None for when it can be either.

**class ArgSession**

Bases: object

A class to keep track of the state accumulated in laying parameters out into memory

**both_iter**

**cc**

**fp_iter**

**int_iter**

**__init__**(*cc*)

**getstate**()

**setstate**(*state*)

**arg_session**(*ret_ty*)

Return an arg session.

A session provides the control interface necessary to describe how integral and floating-point arguments are laid out into memory. The default behavior is that there are a finite list of int-only and fp-only argument slots, and an infinite number of generic slots, and when an argument of a given type is requested, the most slot available is used. If you need different behavior, subclass ArgSession.

You need to provide the return type of the function in order to kick off an arg layout session.

**Return type**
*ArgSession*

**Parameters**
**ret_ty** (SimType | *None*)

**return_in_implicit_outparam**(*ty*)

**Return type**
bool

**stack_space**(*args*)

**Parameters**
**args** – A list of SimFunctionArguments

**Returns**
The number of bytes that should be allocated on the stack to store all these args, NOT INCLUDING the return address.

**return_val**(*ty*, *perspective_returned=False*)

The location the return value is stored, based on its type.

**property return_addr**

The location the return address is stored.

**next_arg**(*session*, *arg_type*)

**Return type**
*SimFunctionArgument*

**Parameters**

- **session** (ArgSession)
- **arg_type** (SimType)

**static is_fp_value**(*val*)

**static guess_prototype**(*args*, *prototype=None*)

Come up with a plausible SimTypeFunction for the given args (as would be passed to e.g. setup_callsite).

You can pass a variadic function prototype in the *base_type* parameter and all its arguments will be used, only guessing types for the variadic arguments.

**arg_locs**(*prototype*)

**Return type**
list[*SimFunctionArgument*]

**x87_arg_locs**(*prototype*)

Locations of the leading arguments passed on the x87 stack.

**Return type**
list[*SimFunctionArgument*]

**get_args**(*state*, *prototype*, *stack_base=None*)

**set_return_val**(*state*, *val*, *ty*, *stack_base=None*, *perspective_returned=False*)

**setup_callsite**(*state*, *ret_addr*, *args*, *prototype*, *stack_base=None*, *alloc_base=None*, *grow_like_stack=True*)

This function performs the actions of the caller getting ready to jump into a function.

**Parameters**

- **state** – The SimState to operate on
- **ret_addr** – The address to return to when the called function finishes
- **args** – The list of arguments that that the called function will see
- **prototype** – The signature of the call you're making. Should include variadic args concretely.
- **stack_base** – An optional pointer to use as the top of the stack, circa the function entry point
- **alloc_base** – An optional pointer to use as the place to put excess argument data
- **grow_like_stack** – When allocating data at alloc_base, whether to allocate at decreasing addresses

The idea here is that you can provide almost any kind of python type in *args* and it'll be translated to a binary format to be placed into simulated memory. Lists (representing arrays) must be entirely elements of the same type and size, while tuples (representing structs) can be elements of any type and size. If you'd like there to be a pointer to a given value, wrap the value in a *PointerWrapper*.

If stack_base is not provided, the current stack pointer will be used, and it will be updated. If alloc_base is not provided, the stack base will be used and grow_like_stack will implicitly be True.

grow_like_stack controls the behavior of allocating data at alloc_base. When data from args needs to be wrapped in a pointer, the pointer needs to point somewhere, so that data is dumped into memory at alloc_base. If you set alloc_base to point to somewhere other than the stack, set grow_like_stack to False so that sequential allocations happen at increasing addresses.

**teardown_callsite**(*state*, *return_val=None*, *prototype=None*, *force_callee_cleanup=False*)

This function performs the actions of the callee as it's getting ready to return. It returns the address to return to.

**Parameters**

- **state** – The state to mutate
- **return_val** – The value to return
- **prototype** – The prototype of the given function
- **force_callee_cleanup** – If we should clean up the stack allocation for the arguments even if it's not the callee's job to do so

TODO: support the stack_base parameter from setup_callsite… ? Does that make sense in this context? Maybe it could make sense by saying that you pass it in as something like the "saved base pointer" value?

**static find_cc**(*arch*, *args*, *sp_delta*, *platform='Linux'*, *unused_hint=None*, *extra_pop=None*, *language=None*, *candidates=None*)

Pinpoint the best-fit calling convention and return the corresponding SimCC instance, or None if no fit is found.

**Parameters**

- **arch** (Arch) – An ArchX instance. Can be obtained from archinfo.
- **args** (list[*SimRegArg* | *SimStackArg*]) – A list of arguments. It may be updated by the first matched calling convention to remove non-argument arguments.
- **sp_delta** (int) – The change of stack pointer before and after the call is made.
- **extra_pop** (int | None) – The number of bytes that are popped by the callee. This is used to distinguish between callee-cleanup and caller-cleanup conventions. None means unknown, in which case callee-cleanup conventions with stack arguments are only matched if no other convention fits the arguments.
- **language** (str | None) – The source language of the binary (e.g. "go"), if known. Languages with their own ABI are matched against that ABI alone.
- **candidates** (list[type[*SimCC*]] | None) – The conventions to consider, overriding the lookup by architecture, platform and language (e.g. the one Go convention a binary's Go release uses).
- **platform** (*str | None*)
- **unused_hint** (*list[SimRegArg] | None*)

**Return type**
*SimCC* | None

**Returns**
A calling convention instance, or None if none of the SimCC subclasses seems to fit the arguments provided.

**classmethod arches**()

**Return type**
tuple[type[Arch], ...]

**get_arg_info**(*state*, *prototype*)

This is just a simple wrapper that collects the information from various locations prototype is as passed to self.arg_locs and self.get_args :type state: angr.SimState :param state: The state to evaluate and extract the values from :return: A list of tuples, where the nth tuple is (type, name, location, value) of the nth argument

class angr.calling_conventions.**SimLyingRegArg**

Bases: *SimRegArg*

A register that LIES about the types it holds

**__init__**(*name*, *size=8*)

**get_value**(*state*, ***kwargs*)

**set_value**(*state*, *value*, ***kwargs*)

**refine**(*size*, *arch=None*, *offset=None*, *is_fp=None*)

**property x87_index: int | None**

i for an x87 stack slot st(i), None for any other register.

angr.calling_conventions.**is_x87_stack_arg**(*loc*)

Whether the argument location is an x87 stack slot, whose register depends on the caller's x87 stack top.

**Return type**
bool

**Parameters**
**loc** (SimFunctionArgument)

class angr.calling_conventions.**SimCCUsercall**

Bases: *SimCC*

**ArgSession**

alias of *UsercallArgSession*

**next_arg**(*session*, *arg_type*)

**class** angr.calling_conventions.**SimCCGoAMD64**

Bases: *SimCC*

Go's register-based internal ABI (ABIInternal), used by the gc toolchain on amd64 since go1.17.

Integer arguments and results are assigned to RAX, RBX, RCX, RDI, RSI, R8, R9, R10, R11 and floating-point ones to X0-X14. Results restart at the beginning of the same two sequences, so a multi-value return comes back in RAX, RBX, … – model it as a struct return type.

RDX carries the closure context pointer, R12/R13 are scratch, R14 pins the current goroutine (g) and X15 is a zero register; none of them are arguments. Unlike the System V ABI, Go assigns registers per scalar leaf rather than per eightbyte, and an aggregate that does not fit entirely in registers is passed wholly on the stack with the register counters rolled back.

**ARG_REGS**: list[str] = ['rax', 'rbx', 'rcx', 'rdi', 'rsi', 'r8', 'r9', 'r10', 'r11']

**FP_ARG_REGS**: list[str] = ['xmm0', 'xmm1', 'xmm2', 'xmm3', 'xmm4', 'xmm5', 'xmm6', 'xmm7', 'xmm8', 'xmm9', 'xmm10', 'xmm11', 'xmm12', 'xmm13', 'xmm14']

**STACKARG_SP_DIFF = 8**

**CALLER_SAVED_REGS: list[str] = ['rax', 'rbx', 'rcx', 'rdx', 'rdi', 'rsi', 'r8', 'r9', 'r10', 'r11', 'r12', 'r13', 'r15', 'xmm0', 'xmm1', 'xmm2', 'xmm3', 'xmm4', 'xmm5', 'xmm6', 'xmm7', 'xmm8', 'xmm9', 'xmm10', 'xmm11', 'xmm12', 'xmm13', 'xmm14']**

Go on 386 only ever had the all-stack ABI0: arguments start at 4(SP), above the return address.

**STACKARG_SP_DIFF = 4**

**CALLER_SAVED_REGS: list[str] = ['eax', 'ebx', 'ecx', 'edx', 'esi', 'edi', 'xmm0', 'xmm1', 'xmm2', 'xmm3', 'xmm4', 'xmm5', 'xmm6', 'xmm7']**

**RETURN_ADDR: *SimFunctionArgument* | None = [0x0]**

**ARCH**

alias of ArchX86

**class** angr.calling_conventions.**SimCCGoARM**

Bases: *SimCCGoStackABI0*

Go on 32-bit arm only ever had the all-stack ABI0. BL leaves the return address in LR and pushes nothing, but 0(R13) at entry is reserved for the callee's saved LR (the prologue's `MOVW.W R14, -framesize(R13)` stores it at the bottom of the new frame), so arguments start at 4(R13). R7 carries the closure context, R10 pins the current goroutine (g) and R11 is the linker temporary; a call clobbers every other register.

**STACKARG_SP_DIFF = 4**

**CALLER_SAVED_REGS: list[str] = ['r0', 'r1', 'r2', 'r3', 'r4', 'r5', 'r6', 'r7', 'r8', 'r9', 'r11', 'r12', 'lr', 'd0', 'd1', 'd2', 'd3', 'd4', 'd5', 'd6', 'd7', 'd8', 'd9', 'd10', 'd11', 'd12', 'd13', 'd14', 'd15']**

**RETURN_ADDR: *SimFunctionArgument* | None = <lr>**

**ARCH**

alias of ArchARM

angr.calling_conventions.**go_cc_class**(*arch*, *versions=None*, *goos=None*, *abi0=False*)

The calling convention the gc toolchain uses for Go functions on `arch`.

Go functions were compiled with the all-stack ABI0 until the register-based ABIInternal was turned on, per GOARCH (internal/buildcfg/exp.go and the release notes):

- amd64: go1.17, but only for linux, android, darwin and windows; go1.18 on every GOOS.
- arm64, ppc64, ppc64le: go1.18. riscv64: go1.19. loong64: go1.22. s390x: go1.27.
- 386 and 32-bit arm: never.

angr models the register ABI on amd64 and arm64 only. Without the exact release (runtime.buildVersion or the build-info blob), the pclntab layout bounds it: layouts older than go1.16 mean ABI0 on both, the go1.16 layout (go1.16-go1.17) means ABI0 on arm64 but either ABI on amd64, and the go1.18 layout or newer means the register ABI. When the release cannot be pinned down, the register ABI is assumed.

**Parameters**

- **arch** (str) – The architecture name.
- **versions** (tuple[tuple[int, int], tuple[int, int] | None] | None) – The (oldest, newest) Go releases ((major, minor)) the binary may have been built with, as returned by *angr.go.utils.version.go_version_range()*; newest is None when unbounded.
- **goos** (str | None) – The binary's GOOS, if known.
- **abi0** (bool) – The function is an ABI0 symbol (the linker suffixes those with ".abi0").

**Return type**
type[*SimCC*] | None

**Returns**
The convention class, or None if angr has no Go convention for `arch`.

angr.calling_conventions.**go_cc_class_for_project**(*project*, *abi0=False*)

*go_cc_class()* for the project's architecture, Go release and GOOS. The release is identified once per project.

**Return type**
type[*SimCC*] | None

**Parameters**
**abi0** (*bool*)

**class** angr.calling_conventions.**SimCCAMD64LinuxSyscall**

**static syscall_num**(*state*)

angr.calling_conventions.**register_default_cc_by_language**(*language*, *arch*, *cc*, *platform='Linux'*)

**Parameters**

- **language** (*str*)
- **arch** (*str*)
- **cc** (type[SimCC])
- **platform** (*str*)

angr.calling_conventions.**register_default_cc**(*arch*, *cc*, *platform='Linux'*)

**Parameters**

- **arch** (*str*)
- **cc** (type[SimCC])
- **platform** (*str*)

angr.calling_conventions.**default_cc**(*arch*, *platform='Linux'*, *language=None*, *syscall=False*, *default=None*)

Return the default calling convention for a given architecture, platform, and language combination.

**Parameters**

- **arch** (str) – The architecture name.
- **platform** (str | None) – The platform name (e.g., "Linux" or "Win32").
- **language** (str | None) – The programming language name (e.g., "go").
- **syscall** (bool) – Return syscall convention (True), or normal calling convention (False, default).
- **default** (type[*SimCC*] | None) – The default calling convention to return if nothing fits.

**Return type**

type[*SimCC*] | None

**Returns**

A default calling convention class if we can find one for the architecture, platform, and language combination, or the default if nothing fits.

angr.calling_conventions.**project_language**(*project*)

The source language to pick a calling convention for, or None when there is no confident answer.

A language-specific ABI reinterprets every argument and return value in the binary, so a detection that rests on something as thin as a single matching symbol name is not acted upon.

**Return type**
str | None

angr.calling_conventions.**default_cc_for_project**(*project*, *syscall=False*, *default=None*)

Return the default calling convention for a project, taking its architecture, platform and detected source language into account.

**Return type**
type[*SimCC*] | None

**Parameters**

- **syscall** (*bool*)
- **default** (*type[SimCC] | None*)

angr.calling_conventions.**unify_arch_name**(*arch*)

Return the unified architecture name.

**Parameters**
**arch** (str) – The architecture name.

**Return type**
str

**Returns**
A unified architecture name.
